The treatment consists in attempting to sterilize the biliary passages by very large doses of urotropine and in promoting biliary drainage. The question of diet I will leave to Dr. McNee. Dr. Knott has shown that the urotropine acts as a biliary antiseptic in spite of the alkalinity of the bile, although it is inactive in alkaline urine and alkaline serum. Consequently its action on the bile is not impaired when sufficiently large doses of alkalis are given to keep the urine permanently alkaline in order to prevent the bladder from being irritated by formalin, which is set free in acid urine. A mixture is prepared containing 100 grains of urotropine to the ounce, and another containing 1 drachm each of sodium bicarbonate and potassium citrate to the ounce. Half an ounce of the former and one ounce of the latter are given after breakfast, after tea, and after a tumbler of milk or water last thing at night. The dose of the urotropine mixture is increased by 1 drachm each day until the full dose of 100 grains of urotropine is taken three times a day. This can often be continued for many weeks without unpleasant symptoms; if any bladder irritation occurs, the dose of urotropine is temporarily reduced, and, if the urine is found to be occasionally acid, more alkali is added to the second mixture. Dr. Knott has recovered urotropine from the bile obtained through a duodenal tube, and in several patients has actually demonstrated the sterilization of infected bile. In most cases we have also given the patient a course of vaccine made from the organism isolated from the bile.

Biliary drainage is promoted by giving magnesium sulphate in concentrated solution one hour before breakfast, in just sufficient quantity to get the bowels satisfactorily opened without the use of any other aperient. My colleague, Dr. J. F. Venables, has demonstrated that magnesium sulphate given in this way produces just as good a flow of bile as when it is introduced direct into the duodenum, so that the unpleasant method of non-surgical biliary drainage recommended by Lyon, in which a duodenal tube is passed every day, is quite unnecessary.

When achlorhydria is present one drachm or more of dilute hydrochloric acid should be given in about five ounces of sweetened water, to which the juice and pulp of an orange may be added, half an hour before breakfast, to help to sterilize the stomach and duodenum, and, with the addition of pepsin, as a beverage with lunch and dinner, in order to make gastric digestion possible. When hyperchlorhydria is present the pain, which is then often very similar to that of duodenal ulcer, can generally be relieved by taking half an ounce of olive oil before meals. This has the additional advantage of causing a flow of bile by a similar reflex to that produced by magnesium sulphate.

I hope I have succeeded in showing how recent advances in our knowledge of the gall bladder have made it possible to diagnose and treat cholecystitis with such success that we may hope that in the future the dissemination of this knowledge will result in a great reduction in the incidence of gall stones.

## GENERAL DISCUSSION.

Dr. F. A. KNOTT (London) said that during the past three years he had made, with Dr. J. F. Venables, slightly over three hundred examinations of specimens obtained by the Einhorn tube. They had particularly followed up those which were surgically proved or clinically almost certain cases of gall-bladder disease, and a few facts from an analysis of this short case series might therefore serve to illustrate the clinical value of this type of test.

It was not necessary to describe the various abnormal elements in duodenal specimens, such as leucocytes, crystals, pigment granules, detached epithelial fragments, and bacteria; but he emphasized the necessity for examining a series of upper alimentary specimens rather than the duodenal contents alone. This series should include the saliva, gastric resting juice, final gastric washings, and the duodenal contents before and after the administration of magnesium sulphate; in this way changes were more readily noted. The speaker thought that in practice it was essential that, after the resting juice had been obtained, the stomach should be thoroughly washed out with distilled water before the tube was passed into the duodenum. In the same way the duodenum should be washed out before obtaining the free flow of bile which was ultimately produced by the magnesium sulphate. This technique tended to reduce contamination and to make the individual specimens more definitely representative.

In routine work one other important point arose. It was not always practicable to confirm the exact position of the tube by x rays; they rarely had the chance to do so. But it was suggested that the results obtained had shown that much clinically useful information could be obtained without this x-ray confirmation. They had noted the following points when deciding the position of the tube. When the end was truly in the duodenum they found (1) a sudden change in reaction of the samples withdrawn; (2) their bulk was very much less; (3) swallowed water could not immediately be withdrawn via the tube; (4) the physical characters and appearance of the duodenal specimens generally differed markedly from the gastric samples; and (5) the typical flow of dark bile after magnesium sulphate was obtained only when the tube was in the duodenum. Admittedly the ideal procedure was to confirm the position by x rays, but if the above conditions were fulfilled the samples might be accepted as satisfactory. In all cases specimens containing food debris or any number of squamous epithelial cells were discarded. Taking these precautions, the speaker and Dr. Venables had examined samples from 71 cases of certain or very probable gall-bladder disease. These cases might be divided into two groups—the first contained 25 cases of gall stones, and the second 46 cases of cholecystitis. In the first, 20 cases were proved to be gall stones at operation, and 5 gave histories of typical gall-stone colic, and from radiological appearances and the van den Bergh reaction were judged to be certain cases of gall stones. In this series only 12 per cent. gave normal duodenal contents after magnesium sulphate. Otherwise 56 per cent. contained either cholesterol crystals or pigment granules, 36 per cent. contained leucocytes or abnormal epithelial debris, 40 per cent. produced pathogenic strains of coliform bacilli, one case the *B. typhosus*, and one *Streptococcus viridans*. In the second series of 46 cases which were considered to be cholecystitis, only 22 per cent. gave normal specimens after magnesium sulphate. In this case 13 per cent. showed crystals or pigment, 26 per cent. contained leucocytes or epithelial fragments, and from 42 per cent. they had obtained coliform bacilli. *B. typhosus* occurred once, streptococci once, and *Staphylococcus aureus* once.

These figures suggested that in practice clinically useful information might be obtained in the cases by the use of the Einhorn tube. With regard to the suggestion that the low gastric acidity predisposed to biliary tract infection, Dr. Knott had noticed that their series did not support this very strongly, as low values were recorded in less than 25 per cent. of these cases. Coliform infection appeared to be much more frequent than micrococcal. In fact, if no coliform bacilli appeared until the bile containing specimens were reached and the gastric acidity had been found to be

normal, then it seemed that serious consideration must be given to the possibility of biliary infection. In examining normal duodenal contents in persons with normal gastric acidity they had found that over 75 were not infected. Dr. Knott had found experimentally that it was possible to sterilize lightly infected bile with very small amounts of urotropine, provided that the tubes were kept at blood heat and that the organisms, continuing at first to multiply, tended to produce acid in their immediate vicinity. At the time it seemed possible that another factor must come into play in producing this sterility—namely, the lowered surface tension, which allowed more effective action by the small amounts of antiseptic present. He had noticed, therefore, with great interest that recently Frobisher in America had been testing the effect of lowered surface tensions upon living bacteria, and had observed that a reduced surface tension was definitely inimical to the growth of many organisms. This was in accord with Dr. Knott's own results, which suggested that antiseptics were somewhat more effective when acting in a medium such as that which bile provided. This did not explain why, experimentally, urotropine was found to be a more effective biliary antiseptic than salicylates. The difference here seemed to arise from the fact that sufficient concentration of salicylate could not be produced in the bile without the appearance of general toxic symptoms, whereas a sufficient concentration of urotropine could be obtained if it was given in the way that Dr. Hurst had already explained.

Professor D. P. D. WILKIE (Edinburgh) considered that cholecystography had already taken its place among the standard methods of diagnosis, but that no finality or perfection had yet been reached. The greater certainty of the intravenous method had led some to persevere in its use to the exclusion of the oral method. The necessity for freshly prepared solutions and meticulous care in injection could not be too strongly emphasized if unfortunate general and local reactions were to be avoided. The immunity of the male sex from symptoms following injection, compared with the female sex, was noteworthy, and possibly of some significance in relation to the comparative immunity of the male from biliary disease. There was no more striking vindication of the importance of physiological research and the experimental method in relation to medical and surgical problems than the work in recent years on the biliary apparatus. The researches of Meltzer and Lyon on duodenal intubation; of Rous and McMaster on the functions of the gall bladder and ducts; of Rosenthal and of Rowntree on liver function tests; of Aschoff and McNeo on jaundice and the reticulo-endothelial system; and, finally, of Graham and his assistants on cholecystography, formed a remarkable record of scientific advance the full significance of which was not yet realized or appreciated.

The exact nature of the gall-bladder function was not yet fully known. The experiments of Dr. Kodama suggested that it played a more purely mechanical role than some had believed. When an organ possessed a muscular coat and was richly supplied with nerves there was strong presumptive evidence that it took more than a passive part in functional processes. The work of Dr. Graham and his associates had also cast doubt on the presumed predominance of the sphincter of Oddi in relation to the physiology and pathology of the biliary tract. They would await with keen interest further evidence on the question of whether they were to recognize for the pars duodenalis of the common bile duct a primary part—namely, a definite measure of independent action and initiative—or merely a secondary role dependent on the peristaltic activity of the duodenal wall. That it must work in harmony with duodenal peristalsis was but natural, and the proving of this did not *ipso facto* preclude the possibility of independent sphincteric function under nerve control.

In cholecystography they had the means of studying the function of the gall bladder and its behaviour under various conditions, as had never been the case before. As experience with the method increased they might be able to recognize kinetic changes in the early stages of biliary

disease and to establish or disprove the existence of the hyper- and hypo-kinetic types of biliary stasis described by Westphal. The gradual disappearance of the gall-bladder shadow, and its uninterrupted persistence when repeated doses of the drug were administered, gave further proofs that the gall bladder never emptied itself completely. This retention of a constant residuum of content might explain in some measure the liability of the gall bladder to calculous disease, as also the relatively silent course which gall-stone cases so often pursued. In Professor Wilkie's experience there was only one condition in which an empty gall bladder was found, and that was a complete obstruction of the common duct or of both hepatic ducts above the entrance of the cystic duct. Dr. Graham's visit to explain and demonstrate his methods and results was emblematic of the catholicity of medicine, of the close bond between the members of the profession in the two nations, and a compliment to the Association which was appreciated very heartily.

Dr. C. F. W. ILLINGWORTH (Edinburgh) stated that cholecystography was in fairly general use in Edinburgh and was becoming an almost routine diagnostic measure. The cases of which he had kept accurate records numbered 132, the great majority of these being under the care of Professor Wilkie. In all of them the intravenous method was used, 4 or 5½ grams of sodium tetraiodophenolphthalein being injected. They had given the drug by the mouth in only a few cases early in their series; the results were not satisfactory. They then commenced to give the dye intravenously, and as by this method the test had proved reliable and without danger, they had hesitated to change the technique. Dr. Illingworth believed, however, that if the oral method could be shown to be equally reliable it was obviously the method of choice. Until, however, complete absorption of the drug from the intestine could be ensured, accurate results could be hoped for only by intravenous injection.

Their technique differed in no essential respect from that of others, but recently they had introduced a slight modification. A few hours before the injection a large dose of magnesium sulphate was given, with the object of securing a partial emptying of the gall bladder and ducts, which were then refilled by the fresh dye-laden bile from the liver. With regard to the after-effects of the injection, their experience had, perhaps, been more fortunate than that of others; only once had any alarming sequel occurred. In this case there was a rather serious collapse before half the fluid had been injected, the collapse persisting for nearly half an hour. A rigor occurred once, but it was transitory and passed off without later ill effect. One patient had a severe headache and one complained of tingling in the limbs. Of the remainder, 61 per cent. suffered no discomfort; the others had varying degrees of nausea or vomiting, never alarming, and invariably passing off in a few hours.

In 111 cases Professor Wilkie had carefully examined the gall bladder at the operation. Dr. Illingworth had classified this series in various groups to illustrate the value of the test.

**Group 1.**—In 39 cases no gall-bladder shadow was present in the x-ray film (which was usually taken twelve to fifteen hours after the injection). Of these patients, 35 were found to present gross disease of the gall bladder or ducts, stones, neoplasm, or well marked cholecystitis, thus confirming the x-ray diagnosis. In the remaining four cases the gall bladder and ducts appeared quite healthy. The reason for this discrepancy was to be found, perhaps, in their technique. In these cases radiograms were taken at one period only, some twelve or fifteen hours after the injection. If a whole series of exposures had been made at varying intervals after the injection a correct diagnosis might have been made.

**Group 2.**—This group included 53 cases in which a gall-bladder shadow of apparently normal appearance was obtained. The results of this group were rather less satisfactory. In 45 the diagnosis was confirmed, the gall bladder being healthy. In the remaining 8, however, the investigation was misleading. One gall bladder contained stones, few in number and too small to be visible on the x-ray film. In 4 a slight degree of cholecystitis was visible to the naked eye. The remaining 3 cases were of particular interest. At operation the gall bladders were of healthy appearance and no stones were present. The clinical histories had, however, been very typical, and it was thought advisable to carry out a bacteriological examination of the bile and the gall-bladder wall. In all 3 cases culture of one or both tissues gave a growth of avirulent diplo-streptococci.

**Group 3.**—This group was a smaller one and required little description. It included those 8 cases where gall stones were visible within the shadow of the gall bladder. It was a point worth mentioning that the concentration of the dye around the stones might be of value as an index of the condition of the gall-bladder wall and as a guide to operative treatment.

**Group 4.**—In 9 cases the cholecystogram was poor and ill defined, and in these cases gross disease of the gall bladder was found to account for the appearance. Reliance could only be placed on the density of the gall-bladder shadow as an index of its functional capacity if the radiogram was a good one; in very stout patients this might be difficult to obtain.

**Group 5.**—There was only one case in this group. The cholecystogram showed a well marked hour-glass deformity, which was found later to be due to a very localized induration of the gall-bladder wall.

**Group 6.**—In patients suffering from obstructive jaundice the investigation had proved of no value. Whether the obstruction was complete or partial, the amount of dye excreted by the liver was insufficient to produce a shadow.

**Group 7.**—The last group included those cases in which a palpable swelling was present in the upper abdomen. In these cases cholecystography had proved of great value. The position of the lump in relation to the gall bladder could be accurately defined and the differential diagnosis was thereby narrowed down. Their series included 5 such cases, and in each the investigation had been of real value. One patient, previously operated upon for an endothelioma in the thigh, developed a swinging temperature and a palpable swelling in the right upper quadrant of the abdomen. Cholecystography revealed a well defined gall-bladder shadow below the level of the lump; a diagnosis was made of secondary metastasis in the liver, and the patient was saved a further operation. In another patient a large epigastric swelling was similarly diagnosed as situated above the gall bladder, and was found to be a large hydatid cyst in the liver. In a third patient the gall bladder was seen flattened and compressed upwards by a tumour which proved to be in the transverse colon. The fourth case was similar, the gall bladder being compressed upwards by a growth in the colon. In the last case a hydronephrosis was responsible for displacing the gall bladder and also rotating it into a horizontal position.

Their conclusions based on this experience were, therefore, that cholecystography was of distinct practical value. The absence of a gall-bladder shadow was strong evidence of gross disease. A good shadow excluded gross disease, but could not be expected to give evidence of minor pathological changes. In jaundiced patients the investigation was of no value, though in their experience it was devoid of risk. Lastly, cholecystography was of considerable assistance in the differential diagnosis of abdominal tumours.

Dr. J. W. McNEIL (London) said he would first deal with recent advances in knowledge of the biliary secretion which normally passes along the bile passages, and with the changes met with in this secretion in disease. It would be remembered that the normal constituents of the bile were water, the pigment bilirubin, the bile acids and their salts, free cholesterol, and a small amount of mucin. In inflammatory disease of the bile passages other constituents, derived from the inflammatory exudate, were present and played an important role in certain end-results, such as the formation of gall stones. The most important of these constituents were, perhaps, the salts of calcium. In considering the biliary secretion in relation to disease it was necessary to remember the great differences between bile as secreted into the intrahepatic bile passages and bile as found in the gall bladder. Professor Graham had referred to the two main functions of the gall bladder—namely, the regulation of the pressure in the biliary passages and the absorption of water. Rous and McMaster had shown that, in the dog, the bile in the gall bladder was concentrated down to roughly one-tenth of its original bulk. The average power of concentration of the human gall bladder was not known, nor had the degree of concentration at which some of the constituents of abnormal bile were almost at the point of precipitation been discovered.

The gall bladder, as was well known to surgeons, could be done without; but it was ridiculous to describe it as a rudimentary organ on this account, or because certain animals had no gall bladder. It would be as logical to describe the spleen, the greater part of the stomach, the large intestine, or even an arm or leg, as rudimentary organs, on the basis of a similar argument. Since too little was known of the functions of the gall bladder, he would put in a word against its surgical removal in the absence of adequate proof that it was diseased and was not recovering.

At the Annual Meeting of this Association two years ago the newer views on the formation of bile pigment in the body had been discussed. This pigment was derived from haemoglobin, and it might be supposed that the amount of the pigment excreted in the bile was dependent on the amount of blood destruction, provided that the parts of the liver concerned with bile pigment metabolism (Kupffer cells and the glandular cells) were functionally intact. There was considerable indirect clinical and experimental support for this simple view—as, for example, the relative frequency of deeply pigmented gall stones in young patients with acholuric jaundice, and the excessive excretion of thick dark bile (pleocholia) in animals after the injection of blood-destroying agents. But other experiments in animals were by no means conclusively in favour of such a simple mechanism. Whipple and Hooper had found very variable results, with no constant increase in the bile pigment, in dogs after injection of large amounts of haemoglobin. These investigators, studying healthy dogs with a biliary fistula, found that on a mixed diet the average daily excretion of pigment was very constant; a large dose of sugar, either by the mouth or intravenously, caused at once a very definitely increased output of pigment lasting for several hours; other carbohydrates acted in the same way. Raw meat, on the other hand, brought about a constant diminution in the amount of pigment excreted. From their experiments Whipple and Hooper had suggested that these facts might upset the accepted theory that bile pigment was only formed when blood was destroyed, but Dr. McNee did not agree with their view.

Numerous attempts had been made to evolve suitable methods of estimating bile acids in health and disease, but at present no satisfactory technique was known. It was inevitable that the presence of increased or of diminished amounts of bile salts would alter enormously the physical properties of the bile. It might even be that the key to many important biliary diseases would be obtained when suitable methods were available. From his own observations Dr. McNee had found that in obstruction of the biliary passages the earliest secretion of the liver to stop entirely was that of the bile acids. As a rule they soon disappeared from the blood and urine when biliary obstruction was complete, whereas bile pigment might pass out in the urine for many months without interruption.

Dr. McNee next dealt with the role of cholesterol in health and disease. There was one controversial point in connexion with the cholesterol content of the bile which was important. Naunyn still believed that cholesterol was actually secreted into the bile from the wall of the gall bladder and biliary passages, but most observers were now opposed to this view, and the speaker thought that from all the experimental evidence available it might safely be assumed that the cholesterol in the bile was derived from the blood plasma by transference through the liver cells. Recent work by Gardner and his associates, by Landau and the speaker himself, had shown that the cholesterol esters of the blood plasma were changed to free cholesterol during their passage through the liver, and that the free cholesterol, when it reached the intestine with the bile, was again absorbed as cholesterol esters. There appeared to be a very conservative metabolism of cholesterol, so that little escaped from the body; what loss occurred was easily made up by absorption from the food, as Gardner had shown. All animal experiments in which the cholesterol ester content of the blood was artificially raised showed at once an increased cholesterol output in the bile. The same fact could be demonstrated in man; and in 1913 Dr. McNee had shown that in pregnancy, during which an increase in cholesterol in the blood was the rule, the same occurred in the bile. He believed that the cholesterol esters in the blood plasma were derived by absorption from the food. French writers had suggested that the suprarenal cortex and the corpus luteum of the ovary were to be regarded as important producers of cholesterol esters for the body. Hurst appears to have accepted this second view without considering the many experimental facts against it. Landau and McNee, after much experimental work, had rejected the French view entirely, and concluded that the suprarenal cortex and corpus luteum were mere depots and not producers of cholesterol esters. Every

experimental increase or decrease in the cholesterol ester content of the plasma was at once reflected in the cholesterol content of these two organs.

With regard to disease of the biliary tract, it was generally agreed that infection of the gall-bladder wall with organisms, as in acute and chronic cholecystitis without calculi, was a common disease and one more often missed than recognized early. By infection was meant a condition associated with definite inflammatory changes in the walls of the gall bladder. The mere presence of organisms in the bile was quite insufficient for such a diagnosis. In all experimental blood infections in animals and in prolonged bacteraemias, such as infective endocarditis, the capillaries of the liver shared with the lung capillaries and the splenic pulp the chief role in removing micro-organisms, and no doubt many living organisms passed out through the bile without harming the biliary tract. It was evident that there were other important factors concerned in the etiology of real cholecystitis. Professor Graham had referred already to the probability of lymphatic infection, and he and his colleagues had done very interesting work in connexion with this and the resulting hepatitis. Stasis of the bile had been in the foreground as an etiological factor for many years, and the speaker thought its position was justified. Recently a new conception had been introduced by the work of the Swedish surgeon Berg of Stockholm, who, from a series of extensive observations on the extrinsic bile passages, had concluded that the form, position, and even the extent of development of certain valves, varied enormously in different biliary tracts and gall bladders, and that therefore certain types of gall bladder were far more prone to stasis and partial obstruction or imperfect emptying because of their anatomical peculiarities. This was a matter of particular interest to surgeons.

How were acute and chronic cholecystitis, without gall stones, to be recognized? The clinical picture might be difficult to interpret and might closely resemble duodenal ulcer, not only in the symptomatology but in the results of examination of the gastric contents. Duodenal drainage might help to some extent, but the speaker felt sure that the correct use of the dye technique introduced by Professor Graham would be recognized as of enormous aid to the clinician. What were the effects on the biliary secretion of cholecystitis, including with it cholangitis, and, as a result of Professor Graham's work, hepatitis also? The bile received, in addition to its usual constituents, all the products of the inflamed gall-bladder wall—an excess of mucin, dead cells and their debris, many of them containing myelin droplets of cholesterol, and last, but not least, calcium salts. The quantitative changes in the biliary constituents during cholecystitis were not known, but quite probably during the acute inflammatory period little new bile entered the gall bladder, and changes were mainly exerted on the bile already there. Precipitation certainly tended to occur, and in that way gall stones might have their beginning.

Many acute infections of the gall bladder must heal altogether. Others died out more slowly, as they could infer from the presence of aseptic bile in pathological gall bladders containing stones. What kept up the inflammatory reaction, and how it should be dealt with apart from surgery, were problems for the future. Dr. McNee could not believe that dietetic treatment was of great value in the prevention of gall stones. While giving an adequate although modified diet, he saw no way of cutting off the small amount of cholesterol that the body needed to replace wastage from the cholesterol metabolism. The metabolism of cholesterol in the body was as conservative as iron metabolism, and it would be almost as logical to try to cure erythraemia by removing the iron in the food required for haemoglobin. The only aim at present must be the prevention of additional damage to the bile passages in patients where this was believed to have occurred. Whether the use of urotropine in large doses, or non-surgical drainage by the Lyon technique, would yield good results in future, was not known. At present the only reliable curative method was surgery. It was important to give ample glucose when possible in diseases of the liver and bile passages. The effects of glucose, when stored as

glycogen, in protecting the liver cells from many poisons were already well known. Whipple and Hooper had shown that sugar also had a definite effect in assisting and increasing the excretion of bile pigment.

Dr. T. IZOD BENNETT (London) dealt with the three great questions which presented themselves to the physician when confronted by signs suggestive of gall-bladder disease. The first of these was whether the evidence of gall-bladder disease was definite. Textbooks asserted that gall stones were chiefly found in fat fertile females of 55, but good aphorisms made bad diagnoses, and they all knew that gall stones were sometimes found in thin males and in quite young and seemingly healthy women, so that physical appearance was of little help. Further, it was known that the symptomatology of cholecystitis and of biliary calculus was immensely varied, ranging from sharp attacks of colic with jaundice to slight feelings of general malaise or even no symptoms at all. On rare occasions it was possible to see a swollen gall bladder through the abdominal wall, or to palpate it, or even to hear with a stethoscope the grating of the stones within it, but usually physical signs were conspicuously absent. While recognizing the value of right scapular pain, of pain below the costal margin together with flatulence, of pain at the right side of the lumbar vertebrae as suggesting gall-bladder disease, it must be realized that these were suggestive rather than decisive. Of the various physical signs, the one most constantly present and of the greatest diagnostic value was the presence of tenderness to pressure below the right costal margin when the patient was examined in the upright position.

The rather unsatisfactory state of the clinical methods of examining these cases had been completely changed by the introduction of cholecystography, and Dr. Bennett did not think it was yet generally adopted in the profession that it was now a comparatively simple matter to obtain precise information in nearly every case. Thanks to Dr. Graham and his colleagues, they had reached a new stage in their knowledge, and the speaker did not hesitate to say that no examination of the biliary tract could be looked upon to-day as complete unless it included x-ray films taken before and after the administration of a suitable dye. In his private practice and at the Middlesex Hospital he had, during the last eighteen months, had the opportunity of seeing a very large number of these cases, and the results of examination had been most satisfactory. They had employed the oral method almost exclusively; not from fear of toxic general symptoms so much as from the risk of occasional venous thrombosis following slight extravasations. Admittedly such should not occur, but, in routine hospital work, such accidents might occur if intravenous injections were given, and a purely diagnostic test which involved such risks was not without grave disadvantages. The difficulties of the oral method were purely those of obtaining a capsule which would be dissolved in the intestine after passing the pylorus unchanged. Variations in the strength of the gastric and pancreatic juices in different individuals were bound to cause trouble in some instances, but the speaker's last fifty cases had been almost uniformly successful, nor had general toxic symptoms ever been grave. Without for a moment doubting his personal results with the intravenous method, Dr. Bennett felt sure that Dr. Graham had not sufficiently stressed the risks of local damage due to extravasation, and he believed that the intravenous method would only become universally applicable when a substance was introduced which was both opaque to x rays and devoid of risk when slight leakage occurred. The second question before the physician was whether the disorder in the biliary tract was permanent or only of a temporary nature. Here again cholecystography was proving of the greatest service, enabling them to watch the progress of cases under medical treatment. Dr. Bennett had seen cases in which the emptying capacity of the gall bladder seemed to improve considerably under treatment, but gross distortions and mottling of the shadow appeared to be always indicative of permanent damage. There was always the further question as to the severity of hepatic change which might have been produced. Here they must bear in mind the fact that

it was probably impossible for infection of the biliary apparatus to have occurred without the liver itself having been subjected to considerable strain during the excretion of bacterial or other poisons. Laboratory tests of hepatic efficiency were still somewhat elementary, or, rather, the immense reserve power of the liver prevented them from demonstrating hepatic damage by laboratory methods until the disease had assumed formidable proportions. The speaker had recently been working with bromsulphalein as introduced by Rosenthal and White. This dye appeared to be absolutely without dangers when given intravenously, and its retention in the blood plasma when a liver was seriously deranged was easily demonstrated and measured. Dr. Davies, in the Biochemical Department of the Bland-Sutton Institute of the Middlesex Hospital, had had promising results with the introduction of certain sugars as tests for hepatic efficiency, but it must be admitted that all these tests at present demonstrated liver disease later in its evolution than they could wish. In earlier cases more useful information could be got by bacteriological examination of bile recovered by means of a duodenal tube; and it was interesting to remember that this was the original application of duodenal tubage. It was possibly its most useful application even to-day.

Turning to the last question before the practitioner, they came to the problem of treatment. Dr. Graham had probably done more to enable patients with biliary tract disease to escape operation than any other surgeon. That was one reason why they welcomed him so warmly. In the absence of stone and gross infection, cases of gall-bladder disease did exceedingly well with medical treatment. Dietetic treatment was very important, but if they thought that by diet they were going to alter the blood cholesterol they were falling into error. The work of Campbell, fully confirmed by unpublished researches in the biochemical laboratories at the Middlesex Hospital, showed that the supposed hypercholesterolaemia of most of these cases was largely a myth. Jaundice and chronic parenchymatous nephritis were the two states which commonly gave rise to an increased blood cholesterol content, and the relief of biliary obstruction would at once reduce the blood cholesterol to normal, independently of the diet. The important dietetic principles in biliary tract disorders were: (1) to give a diet of carbohydrates and vegetables which would improve bowel evacuation and throw a minimal strain on the liver, and which would also combat tendencies to obesity; (2) to give water in abundance; and (3) to utilize such foods as would promote biliary drainage. As regards water drinking, Dr. Bennett was sure that it was of the highest importance. Natural waters with a rather large salt content were usually better than purer waters: normal saline was, he believed, an excellent drink for these patients. The food which most readily provoked emptying of the gall bladder was egg-yolk, and he was trying the effect of giving beaten raw egg-yolk to his patients daily. As to drug treatment, he was convinced that magnesium sulphate in solution, taken on waking, when the stomach was quite empty, was very useful; he did not use Lyon's method of injecting it through a duodenal tube. He believed there was some risk in repeatedly applying such strong solutions to the duodenal mucosa, and he was sure that, given by the mouth, it was easier, devoid of all risk, and equally effective. Bile salts and urotropine were the other drugs which were useful, and these he prescribed in full doses. His experience was that by these methods most satisfactory results could be obtained in a very considerable proportion of cases.

Dr. J. H. ANDERSON (Ruthin) described the results obtained by the use of cholecystography at Ruthin Castle in about fifty cases. The method of administration had varied; at first the dye was given intravenously, but now the oral method was used almost exclusively, being given in salol-coated pills, though in three instances a simple solution was used, as the patients stated that they were unable to take pills of any kind. Comparing the oral and the intravenous method, his experience confirmed the results of previous observers, that at present the intravenous was perhaps more accurate as the dye was more under control; but the oral method was sufficiently

accurate for routine use, besides having certain definite advantages. The possibility of pills remaining unabsorbed or being vomited was checked by a screening of the abdomen and radiological examination of any vomit. The dyes used had been the sodium salt of tetrabromphenolphthalein and tetraiodophenolphthalein prepared by Mallineroth of St. Louis, and in a few cases the sodium salt of tetraiodophenolphthalein prepared by Martindale of London; in all cases solutions were prepared a few hours before use and pills not more than ten days. Ill effects had been insufficient to cause any alarm, and in 20 per cent. of cases there was no reaction at all. In the oral cases the unfavourable sequelae were limited to nausea, vomiting, and diarrhoea. Nausea was transient as a rule, but had once lasted for ten hours in a case where the gall bladder did not fill, and where three stones were found at operation. Vomiting was never severe and never exceeded three times. The largest vomit was in a case where the dye had been dissolved in 60 c.cm. of water. In no case was the vomit stained with the dye. For some time all vomits were x-rayed as a routine, and their density was compared with an equal thickness of tap water as a control, but without detecting the presence of any dye. Diarrhoea was limited to two or three loose motions and was never severe. No indication could be found to show which patient would have a reaction and which not. The impression gained was that the reaction was more likely to occur when the dye was old and in patients whose liver function was impaired. In no case had the test been omitted because of the general condition of the patient, and their experience as to ill effects was contrary to that expressed recently at a discussion in London. In practically all cases a small barium meal had been given at twenty-four hours; one film was taken with the patient lying on the left side and the tube in front of the patient working horizontally. In this way information was obtained as to pressure effects of the gall bladder on neighbouring hollow viscera and the mobility of the gall bladder was ascertained. With cholecystography they could determine in at least 90 per cent. of cases whether the gall bladder was healthy or not. There were some border-line cases, and only time and experience would settle the group into which these cases would fall.

Dr. Anderson showed slides to illustrate some findings confirmed by operation; in all cases the dye was given by the mouth.

Sir BERKELEY MOYNIHAN (Leeds), in congratulating Professor Graham on the great advance that had been made by the introduction of cholecystography, said that in their hands examination by Graham's method had given accurate results in 92 per cent. of cases. He disagreed with some of the observations as to the value of estimating the cholesterol content of the blood. In their early experience they found that as a rule in cases of cholelithiasis there was an increased amount of cholesterol in the blood; 85 per cent. of cases showed an amount above the mean normal, 65 per cent. over the high normal, and 2 per cent. an amount below the low normal. The presence of hypercholesterolaemia, especially when cholesterol crystals were found in the bile extracted from the duodenum, appeared to have a certain diagnostic value. In the last series of 81 cases they had extended their inquiries. They had examined both the cholesterol and the calcium content of the bile, the blood, the gall-bladder wall, and the stones; they had taken into close consideration the stage which the associated pathological conditions in the gall-bladder wall and in the stones themselves had reached. A short interval only elapsed between the examination of the patient's blood before operation and the examination of the gall bladder and its contents.

There was a clear difference between the conditions found in the early stages of cholelithiasis and those found in the late stages. In the early stage an excess of cholesterol was found in the blood, in the bile, and in the gall-bladder wall; there appeared to be a cholesterol "flood" or "high tide." The gall bladder had the property of abstracting cholesterol from the bile, which was heavily charged with it. If the gall bladder was removed early it might present the "strawberry" appearance which he had described

twenty years ago. This appearance was due either to a deposit of cholesterol crystals on the mucosa or to an excess of lipid in the wall of the gall bladder. If this state continued, and if it was preceded or accompanied by infection, the formation of gall stones occurred. These consisted at first almost entirely of cholesterol, as both chemical and radiological examination would prove. In a later stage of the disease, when the stones had caused injury to the gall bladder, which showed evidences of thickening and fibrosis, the conditions were changed. The flood of cholesterol had passed; the high tide was then followed by a low tide. There was no longer an excess of cholesterol in the blood, for the gall bladder, because its mucosa was destroyed, had lost its power of abstracting it from the bile. The chronic irritation of stones had caused the appearance of calcium in the bile, in the gall-bladder wall, and in the blood. Hypercholesterolaemia was changed for hypercalcaemia; and the stones removed from the gall bladder contained calcium. It was interesting to note that a large proportion of private cases fell into the early group, whereas a large proportion of hospital cases occupied the later group. If this view was correct, that the gall bladder extracted cholesterol from the bile, then removal of the gall bladder in patients with hypercholesterolaemia should result in a considerable reduction of the amount of cholesterol in the blood. This they found, on examining cases of cholecystectomy at periods of six months or more after operation, was invariable.

Sir HUMPHRY ROLLESTON (Cambridge) referred to the possibility that although the normal gall bladder might have little, if any, function in the direction of contraction, it might so operate when it was the site of chronic inflammation and accompanying muscular hyperplasia of its walls. He suggested that the good clinical effects following the use of a diet in which cholesterol-producing foods had been reduced to a minimum might be due to some factor other than the cholesterol content. He was not optimistic enough to believe that medical treatment would be able, at any rate for a long time, to eliminate the need for cholecystectomy.

Professor EVARTS GRAHAM, in reply to a question as to the occurrence of "bad arms" at the site of injection, admitted that cases of thrombophlebitis were occasionally seen; he applied heat at once if pain was present. Such cases, however, were rare in skilled hands, and with a new preparation that he was now trying he hoped they might be rarer still.

### THREE CASES OF CHANGED REACTION TO TUBERCULIN FROM POSITIVE TO NEGATIVE.

BY

ROBERT CARSWELL, M.A., M.B., Ch.B.,  
WANDSWORTH.

In the literature of tuberculin comparative charts of the reaction before and after treatment are rare; indeed, specimens of negative charts alone are not common, owing no doubt to the widespread prevalence of latent tuberculosis making it comparatively uncommon to obtain negative reactions in practice. If it can be shown that a positive general reaction can be converted by specific treatment into a negative reaction, after a sufficient interval of time has been allowed to elapse to eliminate the immediate effect of tuberculin immunity, an important step will have been taken towards a valuation of the tuberculin test comparable to that of the Wassermann test in syphilis, and the diagnosis and treatment of tuberculosis will become practicable in the very earliest stage of all—that of infection with minimum pathological changes. The following three cases point in this direction. In the first case it seems fairly clear that the specific treatment was responsible for the conversion of positive to negative reaction. In the second, immunization was only carried to 0.4 c.cm. of the bacillary emulsion (2 mg. bacillary substance); and in the third, which was carried to 4 c.cm. (20 mg.), a long period

elapsed between the first positive test and the two subsequent negative tests. The tedious and laborious nature of these investigations, and the long intervals which must elapse in trials of this sort, will, I hope, justify the publication of only three cases in support of the above proposition.

Chart 1 was obtained in the case of a young man whose general health was reasonably good; the complaint for which he sought advice was a persistent, slightly painful,

obscure affection of the wrist, apparently of no great importance so far as his general health was concerned. The decided positive constitutional reaction unexpectedly obtained led on careful physical examination

to the discovery of slight but distinct physical signs at the right apex. Further importance was given to these facts by a history that the patient had suffered a few years previously from a run-down condition accompanied by a persistent cough, which was thought by his medical attendant to have "touched the lung," although a few months' residence in the country appeared to have re-established his health satisfactorily and cleared up the signs.

Acting on the assumption that this man harboured a tuberculous focus which for the time being was causing no disease in a clinical sense, a wide view was taken of the situation, and thorough treatment, specific and otherwise,

CHART 1.

CHART 2.

which gave hardly a trace of reaction to the first injection (0.001 mg. T.K.); gave a distinct reaction to the second (0.002 mg.), and a pronounced reaction to the third (0.005 mg.). No physical signs were discovered in the chest, but, as before, importance was attached to the test; constitutional and specific treatment was carried out, the maximum dose on this occasion being 0.4 c.cm. (2 mg.), and after an interval of fourteen months from the conclusion of specific treatment the test was repeated, with the negative result shown in Chart 4.

While the temperature record in Chart 4 is not entirely below 98.4°, it is to be noted that the time covered by the

CHART 3.

CHART 4.

was carried out for a period of twelve months. The specific treatment consisted in the subcutaneous injection of progressively increasing doses of Koch's bacillary emulsion, beginning with approximately 0.001 mg. and ending; in the course of about eleven months, with 4 c.cm. B.E. (= 20 mg. solid substance), and carried out more or less in accordance with Koch's final directions for this treatment. The remainder of the treatment was ordinary general care at home. A period of seventeen months from the conclusion of specific treatment having been allowed to elapse, the second test was undertaken for the purpose of comparison, when the completely negative Chart 2 was obtained.

Only when a complete explanation of the meaning of the tuberculin reaction is established will the full significance of these two charts in the medical history of this individual be appreciated. The view to which I adhere, but which for the time being I am not critically discussing, is that at the time of the first chart this patient was suffering from latent tuberculosis, probably at the site indicated by the physical signs, and possibly elsewhere, causing no distinct appearance of bodily ill health, but implying the presence of living tuberculous tissue in active relation with the body fluid, and capable of extension; while at the time of the second chart the negative result indicates that such living tuberculous tissue had been obliterated. That is to say, the tubercle bacilli formerly present and causing the usual

CHART 5.

CHART 6.

later part of the chart was pre-periodic, that event occurring on May 14th. Further, the record of 99° on June 1st was on the third day after the injection; the record of 99.8° on June 6th was also on the third day; that of 99.4° on June 10th was on the second day, and the full test dose of 0.01 mg. on June 13th was followed by still less appearance of disturbance.

Here again the assumption is that in June, 1906, this patient harboured tubercle bacilli in organic relation with the body tissues and fluids, capable of development, and entailing danger of the development of disease similar to that of her sister, while by May, 1908, this condition had been obviated and no such danger remained.

One more example of the same sequence of events is presented.

Chart 5 shows a sharp reaction to a medium test dose of 0.005 mg. In this case there were no distinct focal signs of disease,

although there was certainly a depressed general condition of health. As in the other cases, enough importance was attached to the result of the test to cause steps to be taken to eradicate the infection indicated, which steps consisted in the administration of B.E. up to a maximum of 4 c.cm.

Chart 6 shows the result of a test undertaken after a period of thirteen months from the conclusion of treatment. Here the dose, which had previously caused a sharp reaction with a temperature of 102.6°, resulted on March 28th in a

temperature of only 99°, without constitutional disturbance, in marked contrast to the previous result, while the other test doses of the series were followed by no temperature disturbance at all. This test was repeated twelve months later, with five-day intervals between the injections, instead of two as on the previous occasion (Chart 7).

On this occasion likewise there was nothing approaching a reaction; a temperature of 99.2° on June 3rd was on the fifth day after the first injection and previous to the administration of the second one. A temperature of 99° on June 10th was on the second day after the third injection, and neither of these, nor any of the other

CHART 7.

injections, was accompanied by other than quite trivial symptoms.

The points intended to be brought out in this communication are the striking changes in reactivity to tuberculin in the above cases, together with the means whereby these changes were brought about, and the inferences to be drawn therefrom.

A positive general tuberculin test is a matter of very great practical importance as it is capable of revealing disease at a time when it can be comparatively easily dealt with, and when specific treatment with large doses of tuberculin is easy, safe, and effective.

## HEART DISEASE IN CHILDREN.

BY

G. ARBOUR STEPHENS, M.D., B.S., B.Sc.LOND.,  
CONSULTING CARDIOLOGIST, KING EDWARD VII WELSH NATIONAL  
MEMORIAL ASSOCIATION.

THE results of an investigation into one series of 30 cases of heart disease in children are given in the hope that they will be of some service to those who are interested in this important subject. The cases were sent to the clinic with the object of allowing me the opportunity of determining to what extent there were certain conditions common to those children who were suffering from carditis.

From the accompanying case notes it will be observed that there is a marked liking for acids, especially vinegar, amounting oftentimes to a perversion of appetite. Together with this partiality for acids there is in many cases a great dislike for milk. The aggravation of the choreic movements said to take place in Case 1 after partaking of acids is very strikingly direct. Puffiness of the gums is also a very common factor pointing to a constitutional disturbance closely associated with the alimentary canal. Many of the children are in the habit of biting their nails—a habit indicative of an irritable state of the nervous system, and one which might be said to be preliminary to a choreic condition.

In connexion with these results it may be useful to draw attention to some statistics I collected from the schools under the Swansea Education Committee, of which I have the honour to be chairman.

|   |     |     |             |
|---|-----|-----|-------------|
| No. of children examined                  | ... | ... | 8,638       |
| No. who disliked milk                     | ... | ... | 944=10.9%   |
| No. of nail-biters                        | ... | ... | 3,151=36.5% |
| No. of acid takers                        | ... | ... | 5,469=63.3% |
| No. of those whose gums bleed on cleaning | ... | ... | 2,392=27.6% |

Amount of milk available=0.34 of a pint per head of population.

It will be seen that the condition of a large number of these children can hardly be said to be satisfactory; in fact, such a large amount of nail-biting and gum-bleeding might be described as factors closely associated with a predisposition.

One item in the case notes—namely, "Cardioscope 1-1/2"—must be defined. The usual chest-piece of a stethoscope is barely an inch in diameter, and covers a limited part of the cardiac area. I use a chest-piece nearly 3 inches in diameter, and as a result I find the sounds in a healthy child almost of the same quantity, which I mark "1-1." When the second sound varies and the quantities are unequal, I mark them accordingly "1-1/2" or "1-3/4" as the case may be. Sound quantity is much easier to estimate than sound quality unless the observer has a musical gift. The assumption that medical students are gifted musically is responsible for a wrong conception of

1. Taken with 1-inch receiver from patient sitting up.
2. Taken with 1-inch receiver from patient lying down.
3. Taken with 3-inch receiver from patient sitting up.
4. Taken with 3-inch receiver from patient lying down.

heart sounds on the part of medical men generally. The instrument with this large chest-piece I call a "cardioscope." That such a variation in size of chest-pieces produces different results the accompanying cardiograph diagrams amply testify.

### Heart Cases Examined at the Clinic.

1. Aged 9. Had a fall in January, 1925, followed by a rash and six days later by chorea. She is fond of acids and every time she takes any the chorea is aggravated. She dislikes milk. Left tonsil enlarged and chest narrow. There is no diaphragmatic breathing, and the heart is displaced outwards; no murmur. Cardioscope 1-1/2.
2. Aged 5. Tonsils enlarged, adenoids present, and a discharge from both ears. Can take milk, but is very fond of orange. Heart thrill and mitral murmur present. Cardioscope 1-.
3. Aged 10 1/2. Is stated to have had chorea in November, 1922 when "the movements were slight and the heart sounds rough. Complaints of pain and aches in legs and feels tired. Is fond of vinegar, lemons, and salt. The gums are puffy; there is no heart murmur. Cardioscope 1-1/2.
4. Aged 13 1/2. In November, 1924, the first sound was stated to be "rough." Is fond of vinegar. Gums are puffy; he bites his nails; chest moves badly during respiration. After exercise the first sound is rough. Cardioscope 1-1/2.
5. Aged 8. When examined in July, 1924, and February, 1925, she is stated to have had a "loud systolic bruit." She gets a milk or proper food. Gums puffy; loud systolic murmur. Cardioscope 1-.
6. Aged 8. In 1922 had chorea and in 1923 had chorea and rheumatic fever. Takes no milk but is fond of vinegar. Complaints of pains in legs. Bites nails; gums puffy; systolic murmur. Cardioscope 1-.
7. Aged 10. Stated to have had chorea in 1922, when "the first sound was coarse." "In July, 1924, heart normal." Is fidget about her food. Gums puffy; tonsils and cervical glands enlarged no murmur. Cardioscope 1-1/2.
8. Aged 7. Stated to have had a "soft systolic murmur" in February, 1924, and March, 1925. Very fond of vinegar. Gums puffy; marked mitral murmur. Cardioscope 1-.

9. Aged 9. "In May, 1924, had chorea with a mitral murmur, and in October, 1924, the murmur was still present." Complains of pain over the heart. Dislikes milk, but is fond of vinegar. Tonsils and glands enlarged; nodule on right shin; slight mitral murmur. Cardioscope 1-4.

10. Aged 13. "In March, 1925, had a mitral murmur." Dislikes milk, but is fond of sour things. Gums puffy; marked mitral murmur. Cardioscope 1-4.

11. Aged 11. Stated to have "had anaemia in 1921 and chorea in 1924 with a coarse first heart sound. In February, 1925, heart normal." Takes no milk. Bites nails; gums puffy; no murmur. Cardioscope 1-4.

12. Aged 9. Had chorea in February, 1925. Dislikes milk; gets poor food. Wassermann reaction positive. Tonsils enlarged; adenoids present; keratitis; no murmur. Cardioscope 1-4.

13. Aged 12. Is stated to have had chorea in November, 1923, with enlarged tonsils and sinus arrhythmia, and in March, 1924, chorea with mitral murmur. In October, 1924, the murmur was still present. Takes no milk, but is fond of vinegar. The heart is enlarged with a mitral murmur. Cardioscope 1-4.

14. Aged 13. Is subject to colds; food bad; hopeless mother; another child has chorea. The thyroid is enlarged. Murmur all over the cardiac area. Cardioscope 1-4.

15. Aged 11. In April, 1925, had slight chorea. Dislikes milk. Is always restless; has growing pains; bites nails; gums puffy; no murmur. Cardioscope 1-4.

16. Aged 14. In December, 1923, had operation for right mastoid disease. Dislikes milk. Gets pallid when excited; gums bleed; fond of vinegar; no murmur. Cardioscope 1-4.

17. Aged 12. Does not like milk; fond of vinegar, and "will empty the bottle." Has slight tremors; gums puffy; marked mitral murmur. Cardioscope 1-4.

18. Aged 12. Takes no milk. Has chorea; gums inflamed; tonsils enlarged; bites nails; no murmur. Cardioscope 1-4.

19. Aged 15. Had otorrhoea in 1921 and rheumatic fever in 1924. Takes no milk, but is fond of pickles and vinegar. Bites nails; heart enlarged; mitral murmur. Cardioscope 1-4.

20. Aged 12. Easily fatigued. Dislikes milk, fond of pickles and vinegar. Heart impulse diffused. Cardioscope 1-4.

21. Aged 13. Has been "lackadaisical all her life." Does not like milk; is fond of pickles. Complains of pains over abdomen; bites nails; mitral murmur. Cardioscope 1-4.

22. Aged 11. Mother says "she always wants to sit over the fire and is a terror for vinegar." Gums puffy; poor pulse. Cardioscope 1-4.

23. Aged 11. Had rheumatic fever in 1923. Gets pains in joints when it rains. Takes no milk; is fond of sour things. Tonsils and thyroid enlarged. Gums puffy; bites nails; mitral murmur. Cardioscope 1-4.

24. Aged 13. Is weak and languid; faints when the hair is done. Takes no milk; is fond of vinegar. First heart sound rough. Cardioscope 1-4.

25. Aged 12. Had growing pains; very fond of meat. Gums puffy; bites nails; mitral murmur. Cardioscope 1-4.

26. Aged 13. Takes no milk. Has choreic movements. Gums pyorrhoeic; mitral murmur. Cardioscope 1-4.

27. Aged 12. Takes no milk; is fond of sauce and acid things. Has chorea; bites nails; tonsils enlarged; gums inflamed; marked mitral murmur. Cardioscope 1-4.

28. Aged 15. Had chorea two years ago. Takes no milk; is fond of vinegar. Bites nails; gums puffy; mitral murmur. Cardioscope 1-4.

29. Aged 13. Sister of Case 28. Takes no milk; is fond of vinegar. Has chorea; gums puffy; bites nails; mitral murmur. Cardioscope 1-4.

These two sisters (28 and 29) have one other sister who is very strong. She, however, is fond of milk and does not touch vinegar.

30. Aged 11. Had rheumatic fever six months ago. Takes no milk; is fond of vinegar. Bites nails; mitral murmur. Cardioscope 1-4.

## Memoranda:

### MEDICAL, SURGICAL, OBSTETRICAL.

#### A CASE OF GAS GANGRENE IN LABOUR.

I was engaged to attend the confinement of a woman, aged 35, who had given birth seven years previously to a normal male child.

I examined the patient at seven months' gestation and found a vertex presentation and nothing abnormal. About two weeks before full term (December 3rd, 1925) I was sent for on account of pain in the right side of the abdomen. I was told that foetal movements had not been felt for about two weeks. The presentation was transverse. No foetal movements or heart sounds were obtained; there were no signs of labour. External version was tried, but failed. Quinine was given by the mouth, but no other attempt at induction of labour was thought advisable. On December 12th labour came on normally; the pains were slow.

Dr. Darvall Smith saw the patient with me and performed internal version and pulled down a leg. The foetal head was found to be soft, the skin was peeling off, and the smell of the child was very offensive.

On December 13th the baby was born after great difficulty, owing to the fact that its abdomen was very much distended with gas. Its general condition was very disorganized. There was some post-partum haemorrhage.

For the next few days the mother got on quite satisfactorily, but on December 16th she began to complain of pains in the left

buttock and a small red patch was found at mid-day. At 8 p.m. on the same day it had spread, and I opened where I expected to find pus, but gas was obtained; a drainage tube was put well into the buttock. The inflammation spread very rapidly. Dr. Darvall Smith ordered quinine injections and suggested that the case had become one for a general surgeon. Mr. C. Frankau was called in on December 17th and removed the whole of the gluteal muscles on the right side. The patient died about two hours later.

The bacteriological report upon material from the buttock was: "Films showed large numbers of streptococci and Gram-positive spore-bearing bacilli. By aerobic cultivation both streptococci and the spore-bearing bacillus have been obtained. The later organism is highly pleomorphic; it has a marked tendency to variability on staining with Gram's method, and has a centrally placed spore. It gives rise to profuse gas formation in the cultures, and is strictly anaerobic. The organism is one of the gas gangrene type and is a member of either the *pyrfringens* or the malignant oedema group; its identity is not yet certain."

The question is: How did the patient become infected three to four weeks before full term? The only clue I can offer is that her husband had been badly wounded in France during the war and that some clothes had harboured the spores of these organisms.

HAROLD E. THORN, M.B., B.S.

Harrow.

### GENERAL PARALYSIS ASSOCIATED WITH BENIGN TERTIAN MALARIA.

THE unusual combination of diseases in the following case would seem to render publication desirable.

A retired ship's carpenter, aged 39, was admitted to the Kent County Mental Hospital on January 18th, 1926, with the signs and symptoms of general paralysis, and a history of malaria and heat-stroke. The blood and cerebro-spinal fluid were both reported completely positive to the Wassermann test. The patient was confused, quite disorientated, dirty in habits, with pronounced hallucinations, and very restless. By the beginning of April he had quieted down sufficiently for a course of Stärcke treatment to be begun, but before the fourth injection could be given he had again become very restless and troublesome, and the treatment had to be abandoned. There was then little change in his condition until August 1st, when he had two bouts of fever of 103° with one day intervening, when his temperature was subnormal. The blood was examined and benign tertian malarial parasites were found to be present. Fifteen typical rigors followed, with one or two atypical ones, and, as there was no improvement in his mental condition, quinine treatment was commenced. On September 6th the patient died, having previously developed retention of urine and multiple syphilitic sores.

The interest in this case would appear to lie in the fact that the patient had malaria of long standing and that general paralysis developed in spite of this; a further severe relapse of malaria in no way hindered the progress of the cerebral condition to a fatal termination.

I am indebted to Dr. Abdy Collins, medical superintendent, Chatham, for permission to publish the notes of this case.

GEOFFREY T. BAKER, M.C.,

Kent County Mental Hospital.

L.M.S.S.A. and D.P.M.

### FUNCTIONAL HAEMOGLOBINURIA.

IN view of the interest recently taken in functional albuminuria, the following case appears to be worth recording.

An officer, aged 19, who had recently arrived in Malta and who was not in good training, took part in a cross-country race on April 9th. A short distance from the winning-post he collapsed, and remained unconscious for over an hour.

I saw him in hospital the following morning. Apart from a headache and a sense of general weariness, he stated that he felt quite fit. His pulse was regular and not increased in rate, and there was no evidence of enlargement of the heart, nor were any adventitious sounds or alterations of rhythm detected. The only physical signs of disease which he presented were a slight rise of temperature and well marked haemoglobinuria.

He was kept at rest, and by April 12th the urine was normal in colour, but still contained albumin. By April 15th, the albuminuria had completely disappeared, and did not recur after he was allowed to leave his bed and walk about. He was readmitted to hospital in July for typhoid fever, but on this occasion repeated examinations of the urine failed to reveal albumin.

It seems reasonable to assume that the haemoglobinuria in this case was induced by the excessive exertion and was merely a more advanced stage of functional albuminuria. Probably the same fatigue products which so affected his blood and kidneys were also responsible for the unconsciousness which overcame him at the end of the race, rather than that the latter symptom was the result of cardiac overstrain.

Malta.

Major R.A.M.C.

## A CASE OF MIKULICZ'S DISEASE.

I was greatly interested in the account of two cases of Mikulicz's disease in the *BRITISH MEDICAL JOURNAL* (October 2nd, p. 586), and wish to report an instance of what appears to be the same disease, which came under my notice during the past six months.

A married woman, aged 28, came for advice on account of "her face swelling up." This, she said, commenced about three months after her third confinement which was normal in every way. At this time she presented the appearance of chronic Bright's disease, and was treated for this; at no time had she any albumin or casts in the urine. About fourteen days later she began to complain of swelling in the parotid area on the left side of the face; the swelling was uniform, more flattened than prominent, firm and hard, and extended from the middle of the cheek to the external auditory meatus. The temperature and pulse were normal, and in other respects she felt perfectly well. In three days a similar swelling in the corresponding area of the opposite side occurred. She later developed iritis in both eyes, for which she was treated in York County Hospital. No definite cause for this could be found. There was no history of venereal infection; the Wassermann reaction was negative. A week later, when seen at home, she complained of a hard lump under the chin and excessive dryness of the mouth. The left submaxillary gland was found to be enlarged to about the size of a pigeon's egg, was of dense consistency, and slightly movable; a day or two later the corresponding gland on the right side also began to swell in a similar way. The lacrimal glands were not affected, though there was some definite swelling about the lower eyelids; no other glands could be felt. She also lost considerably in weight. Several drugs were tried without any effect; she has latterly been having iodine, both by the mouth and as an external application. The parotids are now nearly normal in size, and the submaxillaries, especially that on the left side, somewhat smaller than they were; salivation is also returning, though slowly.

I think that this case, in spite of the fact that there was no definite swelling of the lacrimal glands, is very similar to the original one reported by Mikulicz in 1892.

I wish to thank Dr. J. C. Lyth of York for permission to publish this case.

York.

## Reports of Societies.

## "BEFORE AND AFTER OPERATION."

ANNUAL ORATION OF THE MEDICAL SOCIETY OF LONDON BY  
SIR BERKELEY MOYNIHAN.

THE annual oration of the Medical Society of London (postponed from May on account of the general strike) was delivered by Sir BERKELEY MOYNIHAN, P.R.C.S., on October 11th. Sir HUMPHRY ROLLESTON, who on the same occasion was inducted into the chair of the society, presided.

The title of the oration, "Before and after operation," indicates not at all the breadth and eloquence of a deliverance which should long be remembered in the history of medicine. Sir Berkeley Moynihan began by declaring that the distinguishing feature of the intellectual life of the last half-century had been the advance of science. The progress in this respect had been revolutionary. New ideas were expressed in so new a language, and new methods had demanded so new a vocabulary that to the scientist of fifty years ago much of the literature of to-day would be almost unintelligible. The advance had taken place in every department of scientific activity. In some directions it had been stupendous, almost passing belief. Nor was the wonder of it lessened when compared or contrasted with what had been accomplished in other spheres of intellectual work. In painting, sculpture, architecture, and literature, the immediate interests had perhaps been altered, and the methods changed, but when the men who were engaged in these pursuits compared their own ideas and achievements with those of days gone by they were left in a condition of profound and reverent humility. In craftsmanship alone nothing more exquisite had ever been fashioned by human hands than the works which had been concealed for three thousand years in a tomb of Tutankhamen.

*The Pathology of the Living.*

In applied science nothing greater had been done than the progress of surgery since the days of Lister. Lister had been the greatest material benefactor the human race had ever known. He had said it once in Lister's lifetime—and he was interested to learn from Sir Rickman Godlee that nothing gave Lister greater pleasure than to hear it—that Lister had saved more lives than all the wars of all the ages had thrown away. Among the great adventures and the new enterprises which resulted from Lister's work were two things which changed the face of surgery. In the first place there was the possibility of recognizing in an earlier stage than had ever before been accessible the phases of disease at their very beginning. No relevant inquiry into the earliest conditions of disease had ever been possible before Lister's day. In consequence of Lister's work it was possible to see, during the lifetime of the patient, the stages of his disease, and to correlate those stages with structural alterations in a way that could not have been done before; and when operations were, occasionally, fatal it was possible to compare the conditions found on the *post-mortem* table with those which had been discovered during the conduct of the operation. This subjected the surgeon almost at once to a certain amount of derision because the conditions which he had described as being present during the lifetime of the individual did not seem to tally with the conditions found *post mortem*, and, as they all knew, it was only the *post-mortem* pathology which appeared then to have any validity. It was in consequence of a repetition of such criticisms from pathologists that L. coined as a measure of self-protection the title "Pathology of the living," to show that there was a condition present during the lifetime of the patient with which the surgeon was acquainted, and which to him was a matter of supreme importance, different from the condition which existed after death. The lineaments of a man's face changed when he died, and the conditions inside him changed at least to an equal degree. He thought it was a pity that their transatlantic friends should have twisted the phrase into "living pathology," which was not the same thing.

This study of the pathology of the living led not only to a complete revision of old knowledge, it added new knowledge day by day to that which had been accumulated in the past. Let them take, for example, the subject of gastric ulcer and read what Mathew Baillie and others had written, and it would be found that while their writings were perfectly accurate in pathology they had no clinical relevance at all. When the surgeon came along and pointed out that gastric ulcer was a rare disease, not at all the disease which had been described for generations in the textbooks by physicians, it was regarded as almost too good to be true. The first of the conditions, therefore, which resulted from this study of the pathology of the living was a recognition of the much earlier phases of disease, and following upon this was the recognition of the interaction of diseases and of organs one upon another. It was learned that all ulcers in the stomach and duodenum were secondary; that there was an interrelation between the appendix, the gall bladder, and the pancreas, probably through the lymphatic system; much also was learned about the action of the spleen, and so forth.

*Surgery the Instrument of Research.*

Surgery was still, in the orator's judgement, the strongest weapon in the hands of the physician. It was the greatest instrument of research. But it was so little regarded as an instrument of research that even to-day less homage than was due to the surgeon was paid to him. Clinical research, which was the most arduous of all, demanded infinite patience, insight, intellectual integrity, and the power of generalization from a number of observed facts. When experiments were conducted upon animals in the laboratory, with far less anxiety, with no really arduous responsibility, with no clinical responsibility at all at stake, those experiments, brought to fruition, were rewarded with the highest honour which a scientific body in this country could bestow; but when man in all his

bafling multitude of difficulties was subjected to an inquiry the work upon him was not rewarded in the only way in which scientific work could be adequately rewarded in this country—namely, by the bestowal of the Fellowship of the Royal Society. It was one of the saddest things to consider that all this work had been done, the whole face of medicine had been changed, and yet no surgeon in active practice to-day—and no physician—was a Fellow of the Royal Society.

The next point he wanted to make was that the mere craft of surgery was now hardly capable of any further advance. That was a difficult and might seem to be a rash thing to say, but he believed it to be true. If a series of operations were taken—for example, upon the Gasserian ganglion, or upon the stomach or gall bladder, or upon almost any of the organs inside the abdomen, it was really hardly possible for the operations to be much safer than they were now. It was certainly hardly conceivable that there should ever be seen in the whole history of the world greater skill than was shown by the most competent masters of the present time, or that there could be greater beauty of craftsmanship or more perfect execution. There was nothing more perfect in any craft or art than the work of the skilled surgeon. It was evident when one watched such a man that he exemplified, not only supreme devotion and infinite patience, but something like a complete dedication to a great ideal, which was finding expression in the labour of his hands at the moment.

A word of caution was necessary. There was a good deal of bad surgery done, not only in this country, but throughout the world. Men who had some natural gifts had not enjoyed the opportunity, or had refused the opportunity, of training themselves under a great master whose criticism and spiritual encouragement were necessary for the making of a great pupil. Surgery was not learned easily. It required devotion over a long period, and if a man was to be expert in his own day he must first watch the master work and learn from him. If, therefore, the orator was loud in his admiration of the expert surgeon he wanted also to be loud in his denunciation of some bad work practised in the name of surgery to-day. Every surgeon who had had much to do with the work of the last few years would bear out his criticism in that respect.

#### *Earlier Access to Patients.*

If the growth of surgery had advanced as far, or almost as far, as it was possible for it to go, as he thought it had, how could the science of surgery be improved? He believed that an enormous improvement was still possible if the surgeon had earlier access to patients, if he laboured to improve the condition of the patient before operation, and if he took pains to follow up the patient more carefully than was now the custom after the operation was concluded. Surgery was originally rescue work, and surgeons now were constantly doing rescue work, for instance, in connexion with gastric and duodenal ulcer. Was it really right, if they all knew their work and applied themselves properly to it, that there should be so many cases of perforation of gastric and duodenal ulcer in the hospitals to-day? When a series of these cases were examined, as they had been, by Mr. Sherren, or Mr. Walton, or himself, they found that the great majority of the patients who suffered perforation had been treated medically over and over again. There had been neglect somewhere, in the majority of cases, when the perforation of an ulcer occurred, and surgeons had the right—a right conferred upon them by successes extending now back for a great many years—for patients to be delivered to them for surgical treatment at a much earlier stage than was now the case.

The great plea one would make for earlier access would be in cases of cancer. Recently he had inaugurated a Yorkshire cancer campaign because he was rendered so miserable by the series of hopeless cases of cancer of the breast or cancer of the stomach which came along. In connexion with that campaign certain figures were got out under the auspices of the Ministry of Health relating to cases of cancer of the breast at Leeds General Infirmary examined over a long period of years, beginning about 1911. The cases were set out in three groups. The first group con-

sisted of cases in which the breast alone was involved; in the second, the breast and the axillary glands were involved, and in the third the skin was deeply undermined or little satellite nodules were scattered over the surface of the breast. Of those in the first of these groups, 82.2 per cent. were alive and well, and without recurrence three years after operation, and 77.7 per cent. ten years after operation. In the second group 39.5 per cent. were alive and well and without recurrence three years after operation, and 15.8 per cent. ten years after. In the third group, 25.9 per cent. were alive and well three years after, 3.45 per cent. five years after, and ten years after all were dead. He did not think it was possible to put into figures anything more conclusive as to the need for earlier access.

#### *Preparation for Operation.*

The next method by which the results of surgery could be improved was by getting control of the patient some time before operation and doing all that was humanly possible to improve his condition. Before a patient was operated upon certain questions must be answered: first, that the operation was really necessary; secondly, that the patient was in the best possible condition to have the operation performed; thirdly, that the operation thus performed was relevant to the condition for which the operation was called. Observing a smile on the faces of his audience, the orator said that there was a certain humour about it, but there was no humour from the patient's point of view when gastro-enterostomy was done for carcinoma of the colon or tabes dorsalis, or a number of other things, instances of every one of which he had himself witnessed.

Somehow it was always the risks of surgery that were spoken of, never the risks of medicine. In a paper giving the results of ten years' work on gastric and duodenal ulcer he had stated that in the hospital there had been 129 deaths from hæmorrhage or perforation with duodenal ulcer, almost every one of which had been treated medically not once or twice, but over and over again, whereas in the same period he had operated on 531 duodenal ulcers without a death. Which was the safer? Yet when the patient or his medical adviser was asked to consider medical or surgical treatment the view was taken that to enter upon operation was to enter upon a new risk. The fact was that it was much safer for the patient with any of these diseases to be on the operation table than to be on the hospital bed. In medicine lay the great danger—a danger so great in his judgement that much stronger arguments must be brought forward in favour of medical treatment before he at least considered it justifiable after the first attack.

#### *Blood Transfusion.*

In preparing the patient for surgery advantage was taken of a variety of different methods. There was no hurry unless malignant disease was present. The safety of surgery was really proportionate to the care with which the patient was prepared for operation, provided the hands were expert. If one was hurried and had to operate on the morrow, before there was time to examine the patient or make all preparations, a risk was being faced which in the present state of surgery he did not think they were entitled to run. One of the first things he found of use was blood transfusion. He learned this from Crile, and from 1908 onwards he had used it over and over again. In cases of splenic anaemia he could hardly get on without blood transfusion before and after operation. In all cases of splenic anaemia where the blood count came down to 3,000,000 or 3,500,000 blood transfusion was used, not once or twice, but repeatedly, and both before and after operation. In doing a blood transfusion it appeared as if the cholesterol of the recipient were mobilized far beyond the proportion which could be explained by the admission of new cholesterol. Patients were also given glucose intravenously. If the blood cholesterol of the patient was low and the blood urea high then a long time was taken in preparation of the patients, and sometimes there was difficulty with them under these circumstances, though by degrees their confidence was gained. The preparation of the patient who had jaundice had to be undertaken with great care. Years ago they learned the extraordinary

tendency of such patients to bleed after operation. There was a great deficiency in the calcium of the blood of the jaundiced patient. To give calcium orally, as Sir Almroth Wright had suggested, he found to be without value; it was now given intravenously and repeatedly. By the use of this and other methods, including the injection of alien serum, the jaundiced patient had been made much safer.

After operation blood transfusions were continued, as well as infusions of glucose. They might be confronted with acidosis, not uncommonly, or with alkalosis, more rarely. Patients with acidosis required glucose continuously, with or without bicarbonate of soda.

#### *The Surgeon's Training.*

The orator concluded with the remark that his thesis was one which, he was sure, would find general acceptance. It was, briefly, that surgery was no longer a question merely of operating. The work of the surgeon during the last generation or so had created new knowledge and had certainly revised old knowledge very considerably. During that time the surgeon had become a great craftsman, but something more than the finest craftsman was necessary, and he foresaw, in consequence of these changes that were occurring so insidiously in the work of the surgeon, a great change in the surgeon's training. In his own day he thought he had spent far too much time in the anatomy rooms, learning things which, having a rather tenacious memory, he had never been able successfully to forget. A man who was going to practise surgery must be a physiologist, a biochemist, and be steeped in the practice and religion of research. The surgeon could have any number of collaborators, but he himself must be chief. The patient's life was entrusted to him. There was no trust more sacred in the world than that which the patient placed in the surgeon. The operation table was really a high altar and the surgeon the priest. And the patient who had passed through the deep waters with the surgeon might have found them chill and bitter, but the thought of the surgeon's work with him, when the toilsome days were ended, would be like a glowing coal at his heart.

Mr. T. H. OPENSHAW proposed the vote of thanks, remarking that he had never heard more brilliant oratory in medicine. If there was one point in Sir Berkeley's discourse with which he was not in accord it was his reference to anatomy, which the speaker considered must be the absolute groundwork of the surgeon's knowledge, but he fully endorsed all that he had said about pathology and the need for close association between the biochemist and the surgeon.

Sir ARCHIBALD GARROD, in seconding, said that that was not the occasion on which the physician should try to get anything back, though various things might be said in defence of medicine. They had listened to a master of oratory on a subject on which equally he was a master.

Sir BERKELEY MOYNHAN said that he really deserved some recompense, for—although none of his friends believed him—the most dreadful task in the world to him was to deliver a speech! His heart was with the physicians, and he himself was a physician doomed to the practice of surgery. In connexion with a very large share of his work inside the abdomen he owed to Sir Humphry Rolleston more than to any man living or dead. He had never been able to let go of his book. Not that it was everything he would desire from the surgical point of view, but, then, controversy was the delight of scholarship if care were taken that it did not become coarsening.

#### *THE FOTHERGILLIAN MEDAL.*

Before these proceedings took place Sir HUMPHRY ROLLESTON presented the Fothergillian Medal of the society to Professor Sir F. Gowland Hopkins, F.R.S., who, he said, had combined the functions of a great researcher with those of a great instructor. Sir GOWLAND HOPKINS, on receiving the medal, said that he had spent the greater part of his active life in regions quite remote from those in which alone the value of true scientific work could be appraised—that is, the domain of clinical medicine—and it was very encouraging to an experimentalist to have his work recognized in this particular connexion by a society so well able to decide whether it had been of value or not.

#### THE TREATMENT OF GOUT.

At the meeting of the Section of Therapeutics and Pharmacology of the Royal Society of Medicine on October 12th Dr. GEORGE GRAHAM, the President, delivered his annual address from the chair. He took for his subject "The treatment of gout," but made some preliminary remarks on diagnosis.

Dr. Graham began by remarking that there was an impression abroad that gout had become a rare disease, whereas he believed that it still occurred very frequently. During the last two years, in the out-patients' department at St. Bartholomew's he had seen ten cases—four acute and six chronic. In obscure cases the family history was of great value in diagnosis. The actual history of the first joint symptoms when the condition was chronic was also useful. The first attack might be typical in the big toe-joint, though subsequent ones might affect hands or knees. The diagnosis of gout was easily made clinically when the big toe was affected, and also when the carpo-metacarpal joints of the index or ring finger were involved, but it was much more difficult when the affection was of the ankles, knees, wrists, or shoulders. The shape of the joints was nearly always asymmetrical, and this point was of use in making the diagnosis from subacute infective arthritis, where the joints were usually uniformly swollen. The presence of tophi in the ears or swellings of the bursae was significant, but often these did not occur. The changes which took place in the bones due to the deposit of sodium biurate made the skiagram of great value in diagnosis. Sodium biurate, unlike calcium salt, was not opaque to x rays, and when sufficient calcium had been displaced by sodium biurate a clear area would be seen. The changes were best seen in the small bones of the hands or feet, whereas it was rare to detect the changes in a knee-joint because of the thickness of the bone. The changes in the bones must be distinguished from those occurring in lupus pernio and in the arthritis which occurred in association with psoriasis, also from those due to long-standing subacute infective arthritis. The estimation of the uric acid in the blood was sometimes of great assistance in a doubtful case. A high figure for the blood uric acid—above 3 mg. per 100 c.cm.—was strongly in favour of gout, while a low one did not negative the diagnosis.

The first essential in the treatment of an acute attack was that the patient should rest the limb. If the lower limb was affected, bed was indicated; if the upper limb, a sling. In bed the patient should have a cradle to keep off the weight of the clothes. The drug which worked best was colchicum. Its mode of action was in no way understood. It had no effect at all on the excretion of uric acid, but it certainly relieved the pain and cut short the attack. It was of no value in prevention, and it had the disadvantage of sometimes causing unpleasant symptoms, such as dyspepsia, and occasionally severe diarrhoea.

In the prevention of an attack diet played a great part. Dietetic restrictions now, however, were less severe than formerly. The most important was abstinence from all foods containing large amounts of nucleoproteins, such as gland organs like sweetbreads, kidneys, and liver. Meat and fish contained purins, but in less quantity. If it was desired to make the diet very strict, beef might be avoided. The total protein should not exceed from 60 to 80 grams a day. Alcohol in certain forms was undeniably a contributory cause of gout, though its mode of action was unknown. Widal and his co-workers found that patients with gout would often give skin reactions when tested with different wines. Of nineteen cases, three gave very intense reactions, thirteen gave feeble reactions, and three no reactions at all. One lady who gave an intense skin reaction with burgundy always had an attack of gout after drinking any of it. Curiously enough, the wine which had the worst reputation in England—namely, port—did not give skin reactions in Widal's cases. Beer and champagne were considered to be very potent in this country; spirits did not affect patients.

The drug which was of most value was cinchophen, sold in this country under various proprietary names—atophan, agotan, phenoquin, quinophan. In the United States an analysis of the different preparations made by six firms had

been carried out in the laboratory of the American Medical Association, and all were found to be equally pure. In this country the preparations of different firms had not been tested by any central laboratory.

Dr. Graham here related observations made upon one patient—the worst case of gout he had ever seen—from the point of view of uric acid output following the administration of atophan. It was found that the drug only caused a large excretion of uric acid for the first two or three days of its administration, and that the excretion then fell to normal. It was suggested that it was only necessary to give the drug for three-day periods, and then to allow a period with no drugs before starting another course. He adopted this principle, and had treated all his gout cases since on those lines. The patient in this instance had now had the cinchophen preparation for the last six and a half years in 20-gr. doses three times a day for three consecutive days in each week; the total cost to the hospital was about £50. During this period his health had steadily improved. He had had only one attack of gout, on which occasion a mass of sodium biurate weighing about 35 grams was removed by the man himself from a sinus over his knee. He had never had any massage or radiant heat, as his hands were too badly damaged to recover, and the speaker had not thought about the other joints until, after some months, the man came back and said that his knees and ankles were recovering and he could walk much better. Unfortunately no plaster casts had been made of the hands, but the speaker felt sure that the swellings over the knuckles were very much smaller than formerly. Many other patients had been treated on these lines, and the great majority had no acute attacks of gout during the period of treatment and the local condition had improved immensely.

Cinchophen had other purposes in medicine. It was of use in the treatment of acute rheumatism, and relieved the pain just as effectively as sodium salicylate. It had a considerable effect on the liver, and had been used for the treatment of catarrhal jaundice. A certain number of unpleasant after-effects had been noted. Most of these were not serious; they included malaise, headache, intestinal discomfort, and urticaria. In July of this year Dr. Langdon Brown had reported that two patients, one of whom was taking cinchophen and the other the allyl ester of cinchophen, had developed jaundice and died. Other cases of jaundice were reported, and one case was shortly to be published by Dr. Clement Wells in which death occurred four days after the onset of the jaundice. After examining the notes of certain of these cases, Dr. Graham considered that the following facts had been made clear: that it was not the same proprietary preparation in every case which caused the symptoms (in each of the three fatal cases a different preparation was used); the symptoms followed very different doses; the drug in the fatal cases he had examined was given every day of the week without intermission, and in some of the cases there had been definite signs of disturbance caused by the drug, but no attention was paid to them.

Dr. Graham added that he had himself investigated three patients who had been taking cinchophen for long periods, but except in one case—and there the result of the test was doubtful—there were no signs of liver damage. He would suggest by way of precaution that cinchophen should be confined mainly to gout cases; that it should never be given for more than three or four days without an intermission of at least four days; that the blood uric acid should be estimated at intervals of, say, three to six months, and if the blood uric acid was normal the dose should be reduced to two days or only one day in the week. Finally, it was possible that testing the time which was taken for the drug to be excreted might furnish a guide as to whether there was any delay in excreting the drug.

Dr. GEORGE EVANS said that idiosyncrasy to cinchophen did occasionally occur, and he read a letter from the laboratories of one of the proprietary preparations in which this fact was acknowledged. The speaker then went on to give some good results of the treatment. One patient of his took colchicum for a considerable time; then a fresh doctor put him on sodium salicylate, and he was seriously ill. After this he was put on one of the cinchophen pre-

parations (atophan), forty tablets a week. This he took regularly, and gradually himself reduced the dose. He found he kept going best if he took ten tablets a week, and he took them scattered over the week rather than—as the speaker about a year ago suggested—taking them for two or three days in succession with four days clear. The speaker thought that sometimes a better result was obtained by giving atophan, when well tolerated, distributed through the week than by giving it for one-half of the week only.

Dr. W. LANGDON BROWN said that Dr. Graham had been very cautious in the expression of any view about the pathology of the condition. Would he consider that in addition to some definite error of metabolism an attack might be precipitated by some mild infection? An attack might be due, possibly, to some focal sepsis acting on a person who had this peculiar characteristic of his metabolism. If that was the case it would explain why there was so much confusion between gout and rheumatoid arthritis. He remembered how, in the earliest days when cinchophen was used, he employed it in the case of a man who was subject to what he (the patient) called chronic gout. The drug appeared to effect an improvement, and the man himself said that it had done him more good than anything else. Yet on calling for an x-ray examination to clinch the diagnosis the report showed that there were present the typical changes of rheumatoid arthritis. No doubt in that case it was the analgesic properties which enabled him to appreciate it so much. The toxic cases had, of course, produced a serious difficulty. Speaking generally, he had followed the plan of giving the drug for two or three days in the week, followed by a period of rest. The first fatal case he saw had had the drug continuously outside before coming into hospital. In another case the drug was stopped in the course of the illness, and the patient asked that it should be resumed because she felt better during the time she was taking it. It was important to realize that these dangers were more likely to ensue in those cases where the drug was being used for its analgesic properties rather than for its direct effect on the uric acid of the blood; and he would make it a rule not to use the drug for any length of time without having an estimation of the uric acid of the blood carried out. The drug also should not be continued where there was any disturbance, such as urticaria or gastro-intestinal upset.

Dr. E. P. POULTON said that in this condition it was important that all possible sources of sepsis, such as the teeth and tonsils, should be seen to. He thought it was brought out in Dr. Glover's analysis of the chronic joint infections, published by the Ministry of Health, that if one wanted to find cases where the teeth were simply abominable one must go to cases of gout. With regard to diet, Dr. Graham had mentioned that carbohydrates or an excessive quantity of protein were not regarded favourably. In some work which he and Dr. Graham had done together they found that the uric acid in the urine was diminished when either protein or carbohydrate was excluded from the diet. It seemed to him reasonable that there should be some sort of interaction between these two in the formation of these purin bodies.

Dr. F. PARKES WEBER said that he was under the impression that no other disease gave radiological signs really similar to gout, but it appeared from what Dr. Graham had shown that the changes in the bones in lupus perneus were identical with those which gout produced.

A MEMBER OF THE SECTION mentioned that he had been a patient for phlebitis recently at a French spa, and there he was ordered a cinchophen preparation, 15 grains a day, a course lasting three days. He noticed, about ten days after starting, a good deal of tenderness over his liver, and accordingly he dropped the use of the drug. He had taken no alcohol, but large quantities of mineral water.

Dr. GRAHAM, replying to Dr. Parkes Weber, said that many radiologists still needed to learn the x-ray appearances in gout. Another point of interest, suggested by Dr. Poulton's remarks, was that an attack of gout in a gouty subject often followed a trauma. In conclusion, he emphasized the importance of bearing in mind the possibility of any obscure joint lesion being due to gout, because this was one of the few types of chronic arthritis which could really be treated.

## Reviews.

### COMPARATIVE HAEMIC PATHOLOGY.

Dr. J. P. McGOWAN, pathologist to the Rowett Research Institute, Aberdeen, who has done much work on the diseases of animals, has, in a monograph entitled *Pernicious Anaemia, Leukaemia, and Aplastic Anaemia: An Investigation from the Comparative Pathology and Embryological Point of View*,<sup>1</sup> recorded and summarized the results of a research which has been in progress for three years. Beginning with an investigation of Ellermann's leucosis of fowls and iron deficiency in pigs, it has broadened out very considerably so as to lead to a comparison with pernicious anaemia and leukaemia in man and to an inquiry into the embryology of blood formation. From examination of nearly seventy cases of fowl leucosis conclusions different from those of Ellermann emerge; the process is regarded as a pathological entity, an irritative condition of the bone marrow, which may be caused by various factors and not by a specific filterable virus. From careful analysis of the facts, he argues that the leucosis of fowls is comparable to what he terms the "pernicious anaemia-mylogenous leukaemic syndrome" in man, there being the same gradation of morbid processes extending from pernicious anaemia at one extreme through intermediate stages to myeloid leukaemia at the other; some of the intermediate cases were formerly called leukanaemia. In pernicious anaemia the primary change is in the bone marrow. This change may be the direct result of a toxin actually present at the onset of the symptoms, or it may be a delayed sequel of the damage caused by a past infection. The haemolysis, which is generally considered to be due to a toxin of intestinal origin and to be responsible for compensatory hyperplasia of the red marrow, is regarded as the result, not the cause, of the marrow change; for it is argued that the embryonic red cells thrown into the blood are not suited for the adult circulation and so are destroyed by the reticulo-endothelial system, with resulting haemosiderosis and, from the liberated lipids, increased adiposity.

Aplastic anaemia is contrasted with the conditions due to irritation of the bone marrow, and in this connexion attention is drawn to iron deficiency in sucking-pigs, which is a common disease, and prone to be fatal unless ferric oxide is added to their food. In this condition the bone marrow is aplastic, and the liver at first shows fatty change and then blood cells are found in the central zone of the lobules. The deficiency of iron is thought to prevent the liver from assisting in the formation of red cells, and accordingly those that are produced are unsuitable, and are destroyed, but from the lack of iron no haemosiderosis follows. The aplastic anaemia of trinitrotoluene poisoning, in which necrotic changes are prone to occur in the liver, is brought forward as evidence of the importance of the liver in preparing the precursor of haemoglobin, but it is rightly pointed out that in addition the bone marrow is directly damaged by poisons, such as benzol, which lead to aplastic anaemia.

The author's observations on the origin of blood formation also deserve consideration. His conclusions and arguments throughout the book must arrest attention both from the able manner in which they are presented and because of their differences from current doctrines.

### OBSTETRICS AND PUBLIC HEALTH.

*Obstetrics*,<sup>2</sup> by Dr. J. S. FAIRBAIN, has recently been published as one of the Oxford Medical Handbook series. Those who already know the previous works of the author will be prepared for the manner in which this small

volume has been written. It is, admittedly, a task beset with difficulties to compress into so small a book the fundamentals of a large subject—and to lay clearly before the reader the practical applications of the principles involved. We venture to suggest that no writer could have more successfully achieved his object.

Dr. Fairbairn has for a long time taught the necessity of viewing obstetrics as being of prime importance in the consideration of the public health, and in this book he deals fully with this aspect of the subject. The student is to regard a labour, not as an isolated, troublesome occurrence, but one which has both an immediate and a remote important bearing on the life of the woman herself, and on that of the general community.

The author develops the theorem put forward in his book on *Gynaecology and Obstetrics*, published about two years ago, which was that the most useful maternity service should consist of fully trained midwives, acting under the supervision of medical practitioners who would be called on to intervene personally only in times of difficulty. Such a scheme, he believes, would lead to better after-results in both mother and child, and after-results form the test of good obstetrics. This idea is, of course, not new, but an impetus will be given to the proposal by the publication of this book. "The practitioner is between the upper millstone of not neglecting his other patients, and the nether millstone of satisfying and relieving his maternity patients, and it is only the obstetric forceps that saves him from being squeezed between the two"—thus writes Dr. Fairbairn in the last chapter of the book: to ease the lot of the unfortunate practitioner the midwives' services should be more freely employed.

The book makes no attempt to compete with the ordinary textbook. It is written to enlarge the outlook of the student in regard to this specialty, and to guide him in endeavouring to "correct a perspective that is liable to distortion from too close attention to detail." There is much that the student may fail to appreciate fully; but there also is a great deal that will be read with profit by those who are themselves practising only in this special department of medicine. To all interested the volume can be heartily commended.

### PHYSIOLOGICAL CHEMISTRY.

THE laboratory is becoming a little embarrassed with the number of textbooks of practical physiological chemistry offered to it in recent years. Few of these are justified either by their authority or their originality, for they do not stray far from the broad path of conventional teaching. From Dr. P. RONA, however, we have the promise of a manual<sup>3</sup> which, if Part I is representative of the whole, will be both comprehensive and novel. This first part is devoted exclusively to methods for the study of enzyme action. Much foolishness has been spoken and written in the name of "enzymes." The charge is often made that when physiology encounters a phenomenon which it cannot comprehend it invents an enzyme, and there is some justice in the thrust, although we may be tempted to retort that the word is but a label, and as such is as convenient—and therefore equally justified by faith—as are the shibboleths of the physical sciences. The fullness of the role of the enzymes in the processes whose integration is life we cannot yet measure. From chemistry we are learning that there are few reactions free from any catalytic influence under the simplest experimental conditions, and, after all, enzymes are but catalysts. The living organism is essentially an event in time, and it is certain that its life is governed by a subtle control of rates of reaction. To demonstrate an effect in terms of the units of time conventional to human experience would seem to be an achievement of more immediate significance to the study of vital activity than it may be to cosmic or molecular changes of which the dimensions in time we can scarcely comprehend.

The study of enzymes, then, is essentially a problem in physical chemistry, as the school with which the author's

<sup>1</sup> *Pernicious Anaemia, Leukaemia, and Aplastic Anaemia: An Investigation from the Comparative Pathology and Embryological Point of View.* By J. P. McGowan, M.A., M.D., B.Sc. London: H. K. Lewis and Co., Ltd. 1926. (Demy 8vo, pp. vii + 116; 12 figures, 5 plates. 7s. 6d. net.)

<sup>2</sup> *Obstetrics.* By John S. Fairbairn, M.A., B.M., B.Ch.Oxon., F.R.C.P. Lond., F.R.C.S.Eng. Oxford Medical Publications. Oxford Medical Handbook. London: H. Milford, Oxford University Press. 1926. (Fcap. 8vo, pp. x + 221; 25 figures. 5s. net.)

<sup>3</sup> *Praktikum der Physiologischen Chemie.* Erster Teil: *Fermentmethoden.* Von Peter Rona. Berlin: J. Springer. 1926. (5½ x 8½, pp. xi + 331; 73 figures. R.M.15.)

name will always be associated was among the first to realize. Dr. Rona deals first with the general methods in use for making, characterizing, and examining active enzyme preparations. The main portion of the book is then devoted to the special methods which have been developed to deal with the peculiarities of the main groups of enzymes and their action. The treatment is comprehensive yet critical, condensed but explicit, and is cemented with sufficient discussion to give coherence to the whole book, although there has been no attempt at integration in the wider sense. The book is designed for the laboratory, and there it is likely to be in frequent use, and should meet most demands made upon it. We know of no other which so satisfactorily covers this field.

The two further parts of the book which are promised will deal respectively with the body fluids and with metabolism. These will be awaited with interest, though it must be said that in these subjects we have already a number of excellent manuals whose authority will not be easily challenged.

Two years ago the fifth edition of Professor HÖBER's fundamental treatise on the physical chemistry of cells and tissues was commended in these columns. The sixth edition<sup>1</sup> is now in our hands, and comprises, as before, a first section dealing with the physical chemistry of homogeneous and heterogeneous systems, and a second wherein these principles are focused upon the phenomena observable in living cells. How deeply physical chemistry has penetrated physiological thought may be seen in the variety of subjects discussed in the second part. These include the osmotic, ionic, and colloidal characters of the body fluids, the osmotic behaviour of cells and the great question of permeability, the physiological and pharmacological action of electrolytes and non-electrolytes, the electrical properties of cells and tissues, secretion and absorption, and the physico-chemical principles of metabolism. No brief review can give the measure of this large volume. It shows that critical understanding which marks the author's own experimental work, and it remains the most comprehensive and authoritative treatise in what is a very perplexing and elusive field of physiological inquiry.

#### CLINICAL AND RADIOLOGICAL STUDIES OF DISEASES OF THE LUNGS.

It is the privilege of great men to have their works collected and edited after their death. This is of double advantage to the reader, giving him an easy access to the original contributions of the author, and so enabling him to follow the gradual evolution of the mind and abilities of one of the world's acknowledged masters. Dr. EMILE SERGENT, wishing no doubt to facilitate the task of his students, and hoping perhaps to have a foretaste of the posthumous fame that has so frequently been denied to great men, has adopted the habit of collecting his papers for himself. The present volume,<sup>2</sup> which contains clinical and radiological studies of tuberculosis, forms the third of his series. While not disparaging for a moment the laudable intentions of the author, it is easy to take exception to their concrete expression. This has resulted in the accumulation of a number of papers read before societies or conferences, or prepared for different medical journals, which in form and substance are almost identical. It is not to the repetition of ideas that we object—for this is inevitable in the case of anyone who wishes to make a point—but to the actual verbal repetition for which there is no necessity whatever. Had the author taken the trouble to write a book afresh, he could have compressed the same material into about half its present compass.

The range of studies is so wide that it is impossible here to touch on more than a few of them. On the subject of pregnancy and tuberculosis the author suggests that the reason why the disease remains comparatively latent until

term and flares up after parturition is the compression on the bases of the lungs exerted by the child in *utero*. During pregnancy the respiratory excursion is limited; as soon as the compression is relieved the lungs are free to expand fully again, and the lesion progresses. To prevent this he advises the induction of a partial simultaneous bilateral pneumothorax on the day of delivery or as soon after it as possible. Hitherto he has had the opportunity of trying it on only a few cases, and is therefore unable to express more than a tentative opinion. His results are, however, sufficiently encouraging to warrant a fair trial being given to the method.

The examination of the faeces for tubercle bacilli is regarded with increasing favour. When patients cough up their sputum there is, of course no advantage; but in the case of those who habitually swallow sputum, and especially in those very early stages where the diagnosis is doubtful, this method is of great value. In nineteen cases free from sputum the author has been able to prove the existence of pulmonary tuberculosis by the discovery of tubercle bacilli in the faeces. Incidentally he suggests that the bad prognosis of open pulmonary tuberculosis compared with that of the closed type results from a constant reinfection through the intestine by bacilli that have been inadvertently swallowed.

A considerable amount of space is devoted to the radiographical examination of the lungs after intratracheal injection of lipiodol. This compound, which is opaque to x rays, is introduced through the crico-thyroid membrane by means of a syringe, the patient being placed in such a position as will enable the solution to run by gravity into that part of the lung which it is desired to examine. Photographs are taken before and after the injection and carefully compared. The method is chiefly of value in showing up lesions of the bronchi and bronchioles. Such conditions as tracheal deviation, dilatation of the bronchi, bronchial cavitation, and bronchial and pleural fistulae can be diagnosed with a certainty unobtainable by other means. Needless to say, there are numerous errors of interpretation which have to be guarded against.

As to the host of other subjects, too numerous to mention, that are included in this volume, we can do no more than recommend the reader to judge for himself.

#### DIETETICS AND NUTRITION.

PROFESSOR MOURIQUAND's book on dietetics and diseases of nutrition<sup>3</sup> is one of the latest additions to the Collection Testut which is being published by Gaston Doin of Paris. The author's aim is to correlate the study of diseases of nutrition with modern ideas of food values and the physiology of digestion.

There is probably no subject of which the newly qualified student is more ignorant than that of dietetics, and there is perhaps no subject upon which the foundations of a successful medical practice can be more securely based. This is especially true in diseases of infants. Professor Mouriouand devotes almost a quarter of his book to the dietetics of children in health and disease. He writes attractively and clearly, and deals with children at every age from birth to adolescence. His discussion of the development of the healthy child is admirable, the directions he gives for breast-feeding and artificial foods for infants are sound and practical. The explanations of various causes of failure in the feeding of infants are likely to prove most helpful to doctors, nurses, and mothers.

In dealing with adult dietetics he divides his subject into four main headings: (1) general principles which underlie scientific feeding; (2) hygienic rules which should govern the dietary of healthy adults; (3) special dietaries adapted for a variety of pathological conditions, and feeding by artificial means, such as oesophageal and nasal tubes, nutrient enemata, gastrostomy or jejunostomy, intravenous and subcutaneous injections; and (4) the general subject of dietetics in disease.

<sup>1</sup> *Physikalische Chemie der Zelle und der Gewebe*. Von Dr. med. Rudolf Höber. Sechste, neubearbeitete Auflage. Leipzig: W. Engelmann. 1926. (61 x 91, pp. xvi + 855; 125 figures. M.39; bound, M.42.)

<sup>2</sup> *Nouvelles Etudes Cliniques et Radiologiques sur la Tuberculose et les Maladies de l'Appareil Respiratoire*. Par Emile Sergent. Paris: A. Maloine. 1926. (6 x 81, pp. 537; 69 figures on 31 plates. 65 fr.)

<sup>3</sup> *Précis de Diététique et des Maladies de la Nutrition chez l'enfant et chez l'adulte*. Par Georges Mouriouand. Collection Testut. Paris: G. Doin. 1926. (52 x 81, pp. ii + 817; 60 figures, 3 plates. 60 fr.)

Professor Mouriquand arranges his material well. When he discusses the diet appropriate to a certain disease he begins with a short but thorough consideration of the pathology of the disease and the manner in which normal nutrition is interfered with, and then he applies sound physiological principles to overcoming so far as is possible the defects of digestion and assimilation. He does not omit to mention also those drugs which may act as correctives and adjuvants to the dietaries recommended. The chapter on diabetes mellitus is not equal to the general standard of the book. Possibly this may be explained by the difficulties that have stood in the way of a general use of insulin in France. Still the author deserves high praise for the comparatively novel way he has approached a vast and complicated problem.

Dietetics are entering more and more into everyday practice. In many hospitals in America it is customary now to have an official, often a woman, who is responsible for interpreting the directions of the physician and supervising the preparation of the special diets ordered. This plan was adopted in the Edinburgh Royal Infirmary some years ago, when a "Sister Dietitian" was appointed. This is an excellent example to follow, for it conduces to economy in housekeeping, assists in the cure of disease, and adds much to the comfort and enjoyment of the patients.

### IMHOTEP.

DR. JAMIESON B. HURRY, who is well known for his works on vicious circles in disease, and has also written the history of the Reading Pathological Society, has now struck out a new line in his readable and at the same time carefully documented account of *Imhotep, the Vizier and Physician of King Zoser, and afterwards the Egyptian God of Medicine*,<sup>7</sup> who, according to Sir William Osler, is "the first figure of a physician to stand out clearly from the mists of antiquity." Zoser was a Pharaoh of the third dynasty (circa 2980-2900 B.C.). He is commemorated in the step-pyramid of Sakkarah near Memphis, so familiar to visitors of the Nile, which was designed for his royal master by Imhotep, who was a notable architect, was chief lector priest or kheri-heb, was eminent as a writer and the "patron of scribes," as an astronomer, and had a high reputation as a magician and a physician. He has also been described as "the earliest philosopher and wise man known to the world's history." Magic and medicine, in the order of their seniority, were closely allied in early times, and although Imhotep was a famous magician it was his success as a healer of the sick that led eventually to his deification. This is the view generally accepted, but some doubt was cast upon it by Dr. Edith Guest in an article on ancient Egyptian physicians published in the *JOURNAL* on April 17th, 1926 (p. 706). The dates of Imhotep's birth and death are unknown; his father, or at least the husband of his mother, was a famous court architect, but by a double affiliation he was regarded as the son of the god Ptah. About the details of his medical practice history appears to be silent, but he became a medical demigod before 1580 B.C., and his apotheosis as a full God of Medicine occurred about 525 B.C., when Egypt, then conquered by Cambyses, became a Persian province.

Dr. Hurry devotes a special chapter to ancient Egyptian medicine in order to show the extraordinary development of the healing art that had been reached in that country as compared with other parts of the world in the remote time of Imhotep. The practice of mummification and embalming rendered visceral anatomy familiar, and according to the Edward Smith papyrus early Egyptian medical men dissected the human body. The excessive specialism described by Herodotus, one practitioner one disease, appears from recently discovered medical papyri to be an incorrect picture of what actually existed.

Throughout this beautifully illustrated and printed volume there is evidence of the accomplished author's literary research and scholarly taste.

<sup>7</sup> *Imhotep, the Vizier and Physician of King Zoser, and afterwards the Egyptian God of Medicine*. By Jamieson B. Hurry, M.A., M.D. London: Humphrey Milford, Oxford University Press, 1926. (Demy 8vo, pp. xvi + 118; 17 plates. 7s. 6d. net.)

### NOTES ON BOOKS.

MISS MARGARET A. SHUTTLEWORTH has written an excellent little manual on general physiology and hygiene for the use of senior scholars and students in training colleges, under the title *The Wonders of the Human Body*.<sup>8</sup> The general build of the body, the bones of the skeleton, the structure of bones and variations due to dietetic disease, the effects of movement and exercise, the nature of the blood, the circulation, respiration, ventilation, food and digestion, drink, diet and age, excretion, clothing, cleanliness, the nerves and sense organs, and finally infection and the prevention of disease are dealt with. The book is well written, the statements true and, so far as they go, sufficient; the breast-feeding of the infant, prevention of infection by cleanliness and by such measures as vaccination, are well treated. There are no sins of commission, but there is a glaring sin of omission. The mysteries of trypsin, amylase, and lipase are dealt with, but there is never a word that would suggest that mortals have to come into the world somehow. There is a babe at the breast in Chapter XVII, but as to how it got there nothing is said. It surely should not pass the wit of the lady who has written this book to add a chapter describing the growth of a fertilized human egg, and showing that this process is the same for plant, animal, and the human animal. Nothing would curb prurient curiosity better than such a wide generalization.

The perusal of a book by Mr. H. E. Cox on *The Chemical Analysis of Foods*<sup>9</sup> reminds us that methods of analytical examination of these substances have been developed in diverse forms by different experimenters. The experience of everyone who has explored the possible variations of practice is accordingly an acceptable addition to the literature on the subject. But this book, useful as it is in that sense, shares in the defects of other treatises. For the information most to be desired is not merely directions for procedure, but enlightenment on the causes that disturb precision and the ways in which their effects may be avoided or controlled. The treatment accorded to the subject of jams, cordials, and fruit products is sufficiently extensive to merit mention. The concise arrangement of subject-matter is commendable, and the many references to original publications render the work a handy laboratory companion.

In *Goiter and Other Diseases of the Thyroid Gland*<sup>10</sup> Dr. A. S. JACKSON gives a description of the anatomy of the thyroid gland, discusses the etiology and geographical distribution of goitre, and deals with the diagnosis, classification, and treatment of the condition. He recommends that iodine should be administered as a preventive to all persons between the ages of 8 and 20 who live in the large "goitre belt" of the United States, where the disease appears to be extending. He considers that both adenomatous and exophthalmic goitres should receive early surgical treatment. The book is copiously illustrated.

Dr. REGINALD COCK does not believe in evolution, and explains his reasons in a small book, *Genesis v. Evolution*,<sup>11</sup> dedicated to the memory of William J. Bryan, the hero of the evolution trial at Dayton, Tennessee. He advances arguments to prove that man must be descended from a perfect human being, Adam; he seems to attach more importance to the analogy of a butterfly's wing to the wing of a bird than to the homology of the latter with the fore-limb of a squirrel; and he asks what right anyone has to assume a constant progress in the human race when the observation of thousands of years, within the historic period of mankind, furnishes no proof of advance. Progress by mankind, he says, is impossible except through recognition of the archetypal man. Dr. Cock explains where Cain got his wife, and how the whale was able to swallow Jonah. It appears also that Darwinism fosters war, and is the origin of socialism.

Mrs. PEACOCK has compiled a useful little book of recipes, to which is prefixed a table of breakfasts, dinners, and suppers for each day of every month in the year.<sup>12</sup> The object of *The Practical Daily Menu* is to help the housewife in answering the question "What shall we have for breakfast, dinner, and supper?" Emphasis is laid on the facts that different seasons

<sup>8</sup> *The Wonders of the Human Body: A Health Reader for Schools*. By Margaret A. Shuttleworth. London: University of London Press, Ltd. 1926. (Cr. 8vo, pp. xi + 195; 41 figures. 2s. 6d.)  
<sup>9</sup> *The Chemical Analysis of Foods*. By Henry Edward Cox, M.Sc., Ph.D. London, F.I.C. London: J. and A. Churchill. 1926. (Demy 8vo, pp. vii + 323; 38 figures. 18s. net.)

<sup>10</sup> *Goiter and Other Diseases of the Thyroid Gland*. By Arnold S. Jackson, M.D. New York: P. B. Hoeber, Inc. 1926. (Sup. roy. 8vo, pp. xv + 401; 151 figures. 10 dollars.)

<sup>11</sup> *Genesis v. Evolution*. By Reginald Cock, M.R.C.S. Eng. London: Elliot & St. John. 1926. (Cr. 8vo, pp. 172.)

demand different fare, and that food not consumed at one meal can be palatably dished up later. The compilation seems to have been carefully made, but we demur to the statement that one pint weighs one pound. We seem to recollect a jingle stating that "A pint of water weighs a pound and a quarter."

Mr. HORNIBROOK and his wife, better known as Miss ETTIE A. ROUT, seem to be of opinion that the source of all ill health is chronic constipation. In *Physical Fitness in Middle Life*<sup>13</sup> Mr. Hornibrook maintains that the modern cult of athletics is incomplete, and is not followed by self-discipline and suitable exercises in later life. Mrs. Hornibrook, in *Sex and Exercise*,<sup>14</sup> thinks that prolonged constipation is the cause of many female troubles, including frigidity in marriage. Both authors advocate a system of exercises based on native dances as the cure for constipation and its attendant evils. Mr. Hornibrook describes the overloaded colon as the white man's burden, because it ought to be emptied at least thrice a day. He thinks, also, that the inventor of the modern water-closet seat ought to have been slaughtered with his own contraption, since it leads to a wrong posture in defaecation. Mrs. Hornibrook advocates continuous rotary motion, as in the *danse du ventre*, this being conducive to muscular development and organic health. The arguments in the book are supported by quotations from Dr. Leonard Williams, Sir William Arbuthnot Lane, and Dr. A. C. Jordan. To the ordinary person the insistence upon the defects of one portion of human anatomy may perhaps suggest some lack of perspective.

<sup>14</sup> *Sex and Exercise*. By Ettie A. Rout (Mrs. F. A. Hornibrook). Foreword by A. C. Haddon, M.A., Sc.D., F.R.S. London: W. Heinemann (Medical Books), Ltd. (Demy 8vo, pp. ix + 97; 15 figures. 6s. net.)

## PREPARATIONS AND APPLIANCES.

### Bone Skids.

MR. ROBERT OLLERENSHAW, M.D., F.R.C.S. (Manchester), sends us a note regarding a simple instrument which seems likely to prove of use to surgeons in dealing with fractures of the long bones, more particularly, as the accompanying illustrations

FIG. 1.

FIG. 2.

FIG. 3.

FIG. 4.

is a drawing of the instrument, while Figs. 2, 3, and 4 show the method of its use in skidding the fragments.

## MEDICAL SICKNESS, ANNUITY, AND LIFE ASSURANCE SOCIETY.

THE annual general meeting of the Medical Sickness, Annuity, and Life Assurance Society, Limited, was held at the offices of the company, Lincoln House, 300, High Holborn, W.C.1, on October 11th, under the chairmanship of Dr. F. J. ALLAN.

### Chairman's Address.

THE CHAIRMAN, in his opening remarks, referred to the satisfactory progress of the society. He said that though the number of new policies had not been quite so many in the last year as compared with the previous year, it would be remembered that in the preceding year a certain amount of business came to the society through the failure of another company. Allowing for this, a comparison of the figures showed a steady increase year by year. The benefits accruing to members under the sickness and accident policies were the best obtainable, and the directors had decided to give even greater benefits, to apply to both existing and new policies. Among other things, members going on holiday in certain countries for a period not exceeding three months would remain covered without payment of any extra premium. An interesting fact was that though the premium income had almost doubled since the incorporation of the society as a limited company, the claims had only increased from £20,539 to £26,449. The directors always took a sympathetic view of cases in which, perhaps, the requirements under the rules had not been strictly complied with, as, for instance, in a case of serious accident or illness a member might not be able to give notice within the specified time or be in a condition to instruct others to act for him. The directors were, however, careful to get the fullest information in each case, and in difficult and prolonged cases they had even paid specialists to examine the patients. The explanation why the amount paid out had not increased in the same proportion as the increased membership was chiefly due to the careful medical examination of proposers. The society had the great advantage of having a board of directors composed of medical men who were able to bring their knowledge of the various sides of medicine to bear on the problems as well as their long experience in dealing with sickness assurances. He regretted to say that Dr. David Forsyth, who had acted as the trusted medical adviser of the society since 1920, had found it impossible to continue to act for the society; they had, however, been fortunate to secure the services of Dr. A. Hope Gosse, whose work in connexion with cardiology was well known. The life assurance branch continued to advance slowly but surely. The expense ratio had fallen from 7 per cent. to 6.3 per cent., which was less than half the expenditure of most companies. Although the new proposals accepted during the last year showed an increase on previous years, the sums insured for were for lower amounts; this was attributable to the effect of the general depression caused through the coal strike, and nearly all large insurance companies chronicled the same condition of affairs. The quinquennial valuation of the assets of the society would take place on June 30th, 1927. Private valuations held by their consulting actuary, Mr. Warner, indicated a most satisfactory result, provided more normal conditions prevailed during the coming year. The net rate of interest earned had increased from 4.1 per cent. to 4.42 per cent. Every care was taken to ensure that the investments were of the highest grade.

### Election of Directors and Auditors.

The reception and adoption of the report, having been duly moved and seconded, was carried unanimously. Dr. J. Allan and Mr. W. H. Dolamore were re-elected directors, and Messrs. Harber, Sturges, and Fraser were reappointed auditors. A vote of thanks to the manager and the staff for their loyal co-operation in the work of the society was carried unanimously.

In reply to an inquiry from Dr. FAIRFIELD THOMAS, the CHAIRMAN stated that the sickness experienced during the past year had been rather higher than in the last few years; it was, however, still well within the expectation.

### Extraordinary General Meeting.

The business of the ordinary general meeting having been concluded, an extraordinary general meeting followed for the purpose of approving alterations in the articles of association. After hearing from the chairman the reasons for the proposed changes, the meeting approved them. The CHAIRMAN said that the proposed changes would come up for confirmation at a further extraordinary general meeting to be held on November 1st.

A vote of thanks to the chairman, proposed by Sir WILLIAM WILCOX and seconded by Dr. FAIRFIELD THOMAS, was carried unanimously.

## MOTOR CARS FOR MEDICAL MEN.

### NEXT WEEK'S MOTOR SHOW.

By H. MASSAC BUIST.

THE resumed series of motor car shows in the Grand Palais, Paris, closes to-morrow (Sunday) night, and the twentieth yearly International Passenger Car Show, organized by the Society of Motor Manufacturers and Traders, under the patronage of the King, will open at Olympia, Kensington, on Friday next, October 22nd. It will remain open daily, Sunday excluded, until 10 o'clock on Saturday night, October 30th, the prices for admission being 5s. each day, with the exception of the Fridays and Saturdays, when the charge will be reduced to 2s. 6d. The scale of accommodation afforded in the enlarged building may be judged from the fact that, set end-to-end, there will be nearly three and a half miles of exhibits, the cars ranging in cost from £100 to nearly £4,000 each.

### CONSIDERATIONS OF COST.

From the point of view of the average medical man cost takes precedence of all other considerations in respect of his motoring commitments. By cost I mean expenditure not only upon the acquisition but upon the maintenance (that is, the wearing life) of a car, since this matter has to be considered as a whole if one is to aim at obtaining the best value for money. This consideration needs stressing, particularly on the occasion of the forthcoming exhibition, because probably many a young medical man, without capital, will be sorely tempted to consider £100 cars. Doubtless he will read in the general press that the £100 car has arrived at last. In point of fact, the £100 car was standardized and offered to the public by Rover more than twenty years ago; and some of those cars are running to-day. But I do not advise any medical man in general practice to buy any £100 car that will be offered to him at Olympia, notwithstanding the fact that the least of them will have two cylinders, against one in the car of twenty years ago. The prime reason is that reliability and wearing life are essential in a medical man's car. Moreover, even if he is without capital he is not in the awkward predicament in respect of car purchases that those in his case were before the war.

### FINANCIAL FACILITIES.

To-day much over 50 per cent. of the business in selling new motor cars is financed on the principle of payment by instalments. Therefore the medical man can set out in quest of real as distinct from apparent motoring value for money. To that end he must buy a car that has long wearing life. It is not merely that that is the most economical way; incidentally, it is a way that assures him, to a greater degree than any other method of procedure, a machine which shall be reliable no matter what the country of its origin. A long-wearing car must be one every detail of which, including the electrical fittings and so forth, will endure; therefore there will be no rattling loose, perishing of insulations, giving trouble through short circuits, and so forth.

When it comes to a borrowing transaction, one need only pay over a longer period, or slightly more for the usual number of intervals. I notice that one firm in London transacting business in all classes of cars has instituted a new purchase system by payments extending over a period of three years instead of the usual year or eighteen months. I am informed that the management has found the scheme answer very well, alike from the point of view of their clients and from that of the financiers. Consequently the actual bill of the medical man for equipping himself with a car really suitable to such strenuous all-the-year-round day and night service as the general practitioner is dependent upon no longer renders it impracticable for those who for the time being are in straitened financial circumstances to buy really sound cars. Unsatisfactory

cheap cars are unsound, each proving a very expensive car in the long run. Further, the lapse of another year still fails to reveal to my experience a single case of a young medical man setting up in practice who has not found that, by acquiring a thoroughly sound car, he has doubled his income the first year of its use.

### FACTORS FAVOURING THOSE OF MODERATE INCOME.

The medical man must look in other directions than the £100 car if he is in quest of economy in association with satisfactory service. Happily, circumstances favour him. In spite of the coal strike—the effects of which on the motor industry have been severe, leaving many firms with heavy stocks, and putting others in the predicament of a shortage of raw material with which to carry on the production of new car types—prices all round show no increase. In nearly every instance in which the price factor is stationary, nevertheless additional equipment, or something else in the shape of more value for the given sum, is offered. In a great number of cases, of course, prices are reduced notably. Some of these developments are merely occasioned by the necessity to liquidate stock, which would have been disposed of by July last, at the latest, had not a prolonged coal strike upset the car trade. But in many cases reduction of price has been accomplished in association with developing products for the new season, and presenting them more or less in an entirely new guise, because in these factories there has been no accumulation of cars to work off and the captains of the industry have the pluck to carry on. I may mention in passing that when the coal strike is settled it is expected by the British motor industry that it will be quite two months before the flow of raw materials from the steel and auxiliary industries will begin.

In all these circumstances it will be appreciated that the home industry, in particular, is highly to be praised for carrying on, and especially for introducing entirely new designs at prices which represent better value than has ever been offered in the history of the trade, since, obviously, when a firm offers an entirely new superior design the temptation must be great to ask for it as much as it will fetch instead of tempting the buyer by marketing it right away at the lowest price that can possibly be contrived. Another factor in favour of the buyer at this moment is that the tyre industry has just reduced its prices. In some cases these reductions represent the third cut below the maximum prices obtaining during the rubber boom.

### REDUCING THE DEPRECIATION FACTOR.

I have striven to show that one of the most important factors to be considered by the medical man in respect of his expenditure on motoring is the depreciation of the car. The 1926 London Motor Car Show will present him with many examples of vehicles of various powers, so produced as very largely to eliminate the problem of depreciation. This does not concern him only in respect of determining the moment at which he feels he must dispose of his car. On the contrary, it also concerns him by eliminating the frequent necessity for sending his car periodically to the coachmakers for revarnishing, if not actually repainting, often to his great inconvenience as well as no small cost. I refer to the introduction of gun-cotton, or cellulose, finishes for coachwork, a development pioneered by the explosive manufacturers in America. The great transatlantic car builders, who had acquired many of these businesses, found such plant suitable for producing new style finishes for motor cars in the form of lacquers.

The British industry has investigated these developments for a long time. But this is the first season in which there has been any general movement on the part of our manufacturers to standardize lacquer-finished cars which, in any case, are immune from the effects of ordinary scratching, and which, treated as ordinary paint and varnish coachwork is treated, actually improve with use, instead of deteriorating. Further, lacquer finish does what no paint and varnish scheme can do: the former meets the needs of the medical man of moderate means who is called out in the middle of the night to drive through rain and mud, and who, on getting back fatigued, puts his car into the garage—which is ruinous

to ordinary paint and varnish. With lacquer finishes it is not so, though it is advisable to have the car washed as soon as possible after it has become dirtied or wet; but it is not essential. Neglect of this sort by the month can be remedied by very thorough washing and subsequent treatment with one or other of the different special polishes that have been produced. One of the best I have come across has been evolved by a well known maker of boot polishes. Certainly, it takes out any marks of rain-spots and so forth.

#### THE COMING OF LACQUER FINISHES.

The best of these gun-cotton finishes not only improves with use; it is, besides, impervious to the effects of sun, cold, damp, sleet, grit, snow, tar, oil, grease, the heat of the engine under the bonnet, chipping, fading, and so forth. I do not know any one finish used so far by the British industry which embodies all these virtues. Most of those employed embody quite sufficient merits, however, to render them valuable to the motorist, especially to him whose circumstances are those of an owner-driver more or less maintaining his vehicle. For instance, if a cellulose finish does get chipped, the manufacturers can generally fill it over until the lacquer appears as new, because most of these processes are applied by pistol spraying under air pressure. Therefore all that is necessary is to spray and spray until an amount equal to the material lost by the act of chipping has become superimposed on the damaged part.

Some of these lacquer colours, however, are not immune from fading; but even so they do not fade as badly as do some of the lighter tones in paint or varnish. Some manufacturers, too, find that one process of lacquer gives satisfactory results in a given series of colours but unsatisfactory results in other series of colours; therefore they employ different processes, according to the hue they need. This is not always practicable, however, because very elaborate plant has to be laid down to utilize some of the best of these lacquer treatments. By contrast, some varieties can be applied by brush, and will dry in half an hour. Suffice it, however, that the results produced are really worth while. In fact, just as to-day nobody thinks of a passenger car being properly equipped unless it has brakes to all four wheels—though readers of the JOURNAL will remember that only two years ago the matter was still regarded with considerable doubt, not by the public in general merely, but also by the car builders—so in two or three years' time nobody will think of having a cheap car standardized for all-round service the body of which is finished in anything except some form of gun-cotton lacquering. Cellulose lacquers are generally solutions of nitro-cellulose in a mixture of various solvents, such as butyl and amyl acetates, with the addition of suitable gums to toughen the film and give adhesiveness, and also a modicum of plasticizer to make the whole easily workable.

#### NOVELTIES OF NOTE.

The coming of lacquer finishes is exercising another influence on the appearance of cars in general. It presents the opportunity for standardizing hues of a delicacy most pleasing to the eye, eminently suitable for appearance on the open road, but which were not practicable from the maintenance point of view where produced by ordinary coachwork and varnishing schemes. Thus we are on the verge of an era of motor cars of more pleasing and less clumsy appearance. This tendency has even been noted by those charged with designing bodies treated on the ordinary paint and varnish principle: consequently next week it will be evident that the main novelty in the outward appearance of cars finished in conventional fashion is the use of two hues of the main colour scheme, in addition to touches of black here and there on the roofing. This use of two colours in panel fashion represents a development of real note, in that the most expensive motor carriages can be finished more effectively this way than by a reversion to the old coachbuilder's system of fine lines. Of course, the tapestry, linen and silk body coverings that are a novelty at the present French show are a mere attempt to create a passing vogue, and are

not to be considered seriously by motorists in general. A motor car travels so much faster than a horse-drawn vehicle that floral decorative themes, tartan and haggis designs, and small square lines, are not suitable, since the details, attractive or ugly, are alike visible only when the vehicle and the observer are both stationary.

By contrast, the same new British body-colouring scheme is rendered possible by raising radiators. This is a very general practice this year. Thus from the top of the radiator along the saddle of the bonnet to and including the waistline of the car—which is also raised without prejudice to the interior lighting, since the windows reach just as high towards the roof—it is possible to paint a perfectly plain panel of colour. For example, by painting the boot, the waistline, saddle of the bonnet, the wings and the wheels in a darker hue of, say, green than the side panels of the car and the sides of the bonnet, which are a lighter tint, an effect is obtained that can be seen to equal advantage when the vehicle is stationary or in motion. The principle also offers the opportunity to bluff some body lines, which are perforce bulky, or of an awkward angularity or curvature; this is done in some of the bodies on the largest chassis in the world, the new Daimler. Incidentally, an announcement which is timed to be made at the moment these notes appear is to the effect that the oldest firm established in the British industry is introducing a "double six" cylinder engined chassis of nominal 50, actual 150 h.p., the car developing its power in such flexible and smooth fashion that it can be driven at from 2 to 82 miles an hour on top gear, being, therefore, a machine on which one starts on the direct drive and generally completes even a long-distance cross-country journey without coming off it, to judge from various experiments I have had. Such vehicles can be of interest only to the motorist with a very large income. But the reason behind such development should be noted. From the strictly engineering point of view, the whole tendency is to limit the size of the individual cylinder, since, if some of our largest six-cylinder engines were to be made to produce the power they should do for their volume, their performance would become coarse.

#### THE BATTLE OF THE CYLINDERS.

Whenever one speaks with motorists in terms of miles an hour of travel, those facilities should be translated only into increased possibilities of flexibility for hill-climbing, and so forth, since very few people want to travel at more than forty miles an hour in any circumstances. But they would like to be able to maintain such speeds up gradients, especially if that could be done without change of gear. Therefore, the idea is to obtain greater flexibility with refinement, which means greater efficiency with, nevertheless, enhanced as distinct from prejudiced refinement.

Hence we shall see not only the introduction of more eight-cylinder-in-line engine chassis, notably a 35-h.p. type by Sunbeam, and a new 2½-litre type by Beverley-Barnes, also the introduction from America of a Stutz "straight-eight," but also a hint that the middle-size four-cylinder car engine is about to pass away as a type. In general, it may be stated that the builders of middle-size four-cylinder engined chassis tend to provide six-cylinder units instead, especially for vehicles coming within the 12 to 16-h.p. rating. This is merely to give a smoother and more flexible performance.

I foretell that in two years' time a general survey of the industry will reveal to anyone wanting a car of an engine size between our present 12 and 20-h.p. rating that it will be offered him in the form of a six-cylinder unit. Next week I shall deal more particularly with those new six-cylinder cars which come within the purse range of the average medical man, in which connexion I may say that notable fresh contributions are being offered by Clement-Talbot, Wolseley, Lagonda, and Standard in the smaller categories, and by Austin, Humber, and Sunbeam on the larger scale. As to four-cylinder engine practice of the very cheap sort, perhaps the most notable price contribution of the miniature-engined car is the £148 10s. overhead camshaft operated, overhead valve, 850 c.cm. Singer with quarter-elliptic springs fore and aft and rear-wheel brakes only.

### THE "NARRATIVE" OF SIR WILLIAM BEATTY, M.D., LORD NELSON'S SURGEON.

As October 21st is the anniversary of the battle of Trafalgar and of the death of Lord Nelson, many patriotic Englishmen may be interested to read, about this date, a note on the "Narrative" of Sir William Beatty, M.D., Lord Nelson's surgeon.

William Beatty was born in 1773. He was educated as a surgeon, and entered the navy at an early age as a naval medical officer. He was surgeon to the *Victory*, Nelson's ship, at the battle of Trafalgar. Beatty was the author of a famous little book entitled *Authentic Narrative of the Death of Lord Nelson*. It was published in London in 1807.\*

In it Beatty describes the death of Nelson and the autopsy. He records Nelson's last words to himself and those around him. Beatty tells us that on the day of the battle of Trafalgar, October 21st, 1805, after viewing the fleet, Nelson retired to his cabin for a few minutes, and wrote a prayer and a codicil to his will. Beatty describes the meeting of the two hostile fleets and the hoisting of Nelson's famous signal, "*England expects every man will do his duty*," about half an hour before the enemy opened their fire; and he tells us it is impossible to describe "the lively emotions excited in the crew of the *Victory*." The battle commenced at 50 minutes past 11. Early in the engagement a shot passed between Lord Nelson and Captain Hardy, bruising the foot of the latter, and Nelson remarked, "This is too warm work, Hardy, to last long." In the heat of the battle, about 1.15, Lord Nelson "was walking the middle of the quarter-deck with Captain Hardy, and in the act of turning near the hatchway," when a bullet "from the enemy's mizzen-top" struck the epaulette on his left shoulder and penetrated his chest, and he fell with his face on the deck. When Captain Hardy expressed a hope that he was not severely wounded, Nelson replied, "They have done for me at last, Hardy. . . . My backbone is shot through."

When carried below to the cockpit Beatty was called, and Nelson remarked: "Ah, Mr. Beatty! you can do nothing for me. I have but a short time to live; my back is shot through." When examined by his surgeon Nelson said he was confident his back was shot through; that he felt a gush of blood every minute within his breast; and that there was loss of feeling and motion in the lower part of his body. His breathing was difficult, and he complained of acute pain about the sixth or seventh dorsal vertebra. Nelson frequently asked for drink, and to be fanned with paper, using the words "Fan, fan!" and "Drink, drink!" These words he continued to repeat until the end.

To Captain Hardy many messages were sent requesting him to come to Nelson. When Captain Hardy came, Lord Nelson said, "Well, Hardy, how goes the battle? How goes the day with us? I hope none of our ships have struck, Hardy." "No, my Lord, there is no fear of that," replied Captain Hardy. Then Nelson said: "I am a dead man, Hardy; I am going fast; it will be all over with me soon. Come nearer to me." When Captain Hardy said that he hoped Mr. Beatty could yet hold out some prospect of life, his Lordship answered: "Oh! no, it is impossible. My back is shot through. Beatty will tell you so." His Lordship then sent his surgeon away to attend to the other wounded, saying, "You can do nothing for me."

But shortly afterwards Lord Nelson recalled him, and said: "Ah, Mr. Beatty! I have sent for you to say, what I forgot to tell you before, that all power of motion and feeling below my breast are gone, and you very well know I can live but a short time."

The emphatic manner in which he pronounced these words left no doubt in Mr. Beatty's mind that Nelson was thinking of the case of a man who had, some months before, received a mortal injury of the spine on board the *Victory* and had suffered from similar loss of sensation and paralysis. The case had made a great impression on Lord Nelson, and the cause of the symptoms had been explained to him. Mr. Beatty replied, "My Lord, you told me so before," and when he examined the legs to ascertain the fact, Nelson remarked, "Ah, Beatty! I am too certain of it; Scott and Burke have tried it already. You know I am gone." Beatty replied, "My Lord, unhappily for our country, nothing can be done for you." Soon afterwards Nelson said, "I know it. I feel something rising in my breast, which tells me I am gone." He often exclaimed "God be praised, I have done my duty." When Mr. Beatty inquired if the pain was severe, Nelson replied it was so severe that he wished he was dead, and then he added, "Yet one would like to live a little longer, too." Hardy then came a second time, and congratulated Nelson on the brilliant victory, informing him that fourteen or fifteen of the enemy's ships had surrendered. Nelson answered, "That is well, but I bargained for twenty," and then he exclaimed "Anchor, Hardy, anchor!" Soon Nelson remarked that he felt in a few minutes he should be no more, and added in a low voice, "Don't throw me overboard, Hardy"; and then came his request, "Kiss me, Hardy." Captain Hardy now knelt down and kissed his cheek, when his Lordship said, "Now I am satisfied. Thank God, I have done my duty." In a few minutes Hardy again knelt down and kissed Nelson's forehead. "Who is that?" said Nelson. The Captain replied, "It is Hardy," to which Nelson replied, "God bless you, Hardy!" Hardy now returned to the quarter-deck, and Nelson said to his chaplain, Dr. Scott, "Doctor, I have not been a great sinner." As long as he was able to give utterance Nelson continued to repeat, "Thank God, I have done my duty." These were his last words. He then became speechless, and died at 4.30 p.m., about two hours and forty-five minutes after being wounded.

The day after the battle Nelson's remains were placed in "a cask called a leaguer," which was then filled with brandy. At Gibraltar spirit of wine was procured. The body was then conveyed to England. On arrival at Spithead a post-mortem examination was made, and Beatty gives a concise professional report. The bullet was discovered lodged in the muscles of the back, towards the right side, and a little below the shoulder-blade. It had passed through the spine. As regards the course of the ball, Beatty reports:

"The ball struck the forepart of his Lordship's epaulette, and entered the left shoulder immediately before the process acromion scapulae which it slightly fractured. It then descended obliquely into the thorax fracturing the 2nd and 3rd ribs; and after penetrating the left lobe of the lungs, and dividing in its passage a large branch of the pulmonary artery, it entered the left side of the spine between the 6th and 7th dorsal vertebrae, fractured the left transverse process of the 6th dorsal vertebra, wounded the medulla spinalis, and fracturing the right transverse process of the 7th vertebra, made its way from the right side of the spine, directing its course through the muscles of the back; and lodged therein, about 2 inches below the inferior angle of the right scapula."

The immediate cause of death was a wound of the left pulmonary artery and the resulting haemorrhage. The injury to the spine must of itself have proved fatal, in Beatty's opinion, in two or three days.

After the battle of Trafalgar, Beatty was appointed, in 1806, physician to the Greenwich Hospital. In 1817 he obtained the degree of M.D. St. Andrews and the diploma of L.R.C.P. Lond. In 1818 he was elected F.R.S., and was knighted in 1831. He died in London in 1842.

R. T. WILLIAMSON.

\* In 1891 a neat edition of this book was published in Birmingham, under the title of *The Death of Lord Nelson*, by William Beatty, M.D., surgeon to H.M.S. *Victory*. The War Library Series, edited by Professor Ed. Arber.

## British Medical Journal.

SATURDAY, OCTOBER 16TH, 1926.

### RECENT WORK ON THE BILIARY SYSTEM.

THE discussions in the Section of Medicine at the Nottingham meeting of the British Medical Association were on broad lines, and wisely dealt with subjects on the borderland between medicine and surgery, such as diseases of the biliary tract, blood transfusion, and the nature and treatment of malignant neoplasms. The discussion on some recent developments of knowledge of the biliary tract (reported in full this week at page 671) was, indeed, opened by a distinguished surgeon, Professor Evarts A. Graham of Washington University, St. Louis, U.S.A., who has done pioneer work, not only in demonstrating the almost constant association of hepatitis with cholecystitis, but in originating cholecystography. A somewhat unusual but most welcome feature of a Medical Section of the Association was the presence of the President of the Royal College of Surgeons of England, Sir Berkeley Moynihan, who joined in the discussion of a subject which he has done so much to advance.

The summary of the functions of the gall bladder—namely, regulation of pressure in the biliary system, as shown by cholecystography, and concentration of the bile, as brought out by changes in the density of the shadow—was supplemented later by a discussion of the question whether or not the gall bladder has the power of muscular contraction. The opener's opinion, based on experimental work in his laboratory and on observations made during numerous laparotomies, is that the gall bladder has not any power of active muscular contraction, changes in its size being the result of a milking action induced by duodenal peristalsis. In this connexion reference may perhaps be made to Chiray and Pavel's<sup>1</sup> experiments on dogs, which show by tracings from the gall bladder that it undergoes two kinds of spontaneous contractions, which, however, are rarely manifest to the naked eye. The tracings of these apparent contractions can perhaps be explained in some other ways. It may be recalled that Bainbridge and Dale's periodic waves of contracture have since been regarded as resulting in fact from pressure of adjacent organs and respiratory movements, for Professor Graham's associates Copher and Kodama have obtained curves similar to those of Bainbridge and Dale when a rubber bag is substituted for the gall bladder, and experimental work from the opener's laboratory, just published,<sup>2</sup> indicates that the contents of the gall bladder are got rid of by a three-fold mechanism—a gradual washing out by the ingress of fresh bile from the liver, the elastic recoil of the gall bladder, and variations of the intra-abdominal pressure. This experimental evidence is much against the late S. J. Meltzer's hypothesis of contrary innervation of the gall bladder and Oddi's sphincter, on which the technique of Lyon's method of diagnosis and treatment by biliary drainage is based. Oddi's sphincter at the lower end of the common bile duct is stated not to be constantly present, and Professor Evarts Graham considers that the outflow of bile into the bowel is controlled by the tonus and peristalsis of the

duodenum. On the other hand, McMaster and Elman<sup>3</sup> of the Rockefeller Institute for Medical Research, in two papers published since the Nottingham meeting, bring forward strong evidence that the gall bladder of the healthy unanaesthetized dog contracts after a meal with sufficient force to expel part of its contents against a considerable resistance pressure, and that Meltzer's law of contrary innervation, which has been much disputed, holds good—namely, that the tonic contraction of Oddi's sphincter at the lower end of the common bile duct relaxes when the gall bladder contracts. In this research the objections raised against both the contracting power of the gall bladder and Meltzer's law are taken fully into account, and it is suggested that the effects of operations and anaesthesia may account for the negative evidence of gall-bladder contraction obtained by Professor Evarts Graham and others.

Inflammation of the gall bladder is regarded in America as the commonest cause of dyspepsia, and Dr. A. F. Hurst considers it the most frequent intra-abdominal lesion. Professor Graham showed that this might spread by the lymphatics both from and to the liver, and he admitted in addition the advent of infection by the blood stream, by the lymphatics from a duodenal ulcer without any hepatitis, and also direct infection of the mucosa from micro-organisms in the bile, this being about the order of their respective importance. Just as cholecystography throws light on the functional state of the gall bladder, so too it elucidates pathological changes by revealing failure of bile to enter the gall bladder, defects due to the presence of calculi, and irregularities of contour due to adhesions and diverticula; it shows also variations in the normal density of the shadow, though the bearings of these are still open to further interpretation.

The history of cholecystography, introduced so lately as 1923 by Professor Graham in conjunction with W. H. Cole, is most interesting. Of the forty-one substances tried, twelve were found to outline the gall bladder, but only three of these—tetrabromphenolphthalein, tetraiodophenolphthalein, and its isomer, phenoltetraiodophthalein—are suitable for clinical use, the other nine having markedly toxic effects. After due trials of the first two the tetraiodophenolphthalein was employed and given intravenously, as this method is more reliable than the oral administration, which Dr. Izod Bennett,<sup>4</sup> who raised the question of the drawbacks due to thrombophlebitis after intravenous injection, had found uniformly successful in his last fifty cases. In Professor Graham's more recent experience there were fewer reactions after the new isomeric compound, the sodium salt of phenoltetraiodophthalein, than after the tetraiodophenolphthalein salt, and, as there had not been any alarming symptoms after its use in the last 500 cases, he felt justified in concluding that this danger had been eliminated. Out of 1,144 patients examined cholecystographically with the tetraiodo salts, 128 were operated upon, and in 124, or 96.9 per cent., of these the diagnosis made by cholecystography was confirmed.

In the discussion Dr. A. F. Hurst insisted on the importance of early diagnosis and medical treatment, and advocated large doses, up to 100 grains three times a day, of hexamine, with sufficient sodium bicarbonate and potassium citrate to keep the urine alkaline, and so prevent irritation of the urinary

bladder. The mechanism of the antiseptic action of hexamine in the bile was further discussed by Dr. F. A. Knott, who suggested as one factor lowering of the surface tension of the bile. The cholesterol content of the blood was referred to by several speakers. Dr. Izod Bennett mentioned that his colleague Professor E. C. Dodds, in a paper in the press, had reached the same conclusion as Dr. J. M. H. Campbell—namely, that the supposed hypercholesterolaemia of cholelithiasis was largely a myth, and that an excess of cholesterol in the blood was mainly due to chronic parenchymatous nephritis and obstructive jaundice. Dr. J. W. McNee's opinion that, although cholesterol is derived from the food, a cholesterol-free diet is not of any real value in the prevention of gall stones, is obviously of much therapeutic importance, especially as yolk of egg and fats, which are rich sources of cholesterol, have a powerful effect in evacuating the gall bladder. Sir Berkeley Moynihan, who had found that Professor Graham's cholecystography gave a correct diagnosis in 92 per cent. of the cases, pointed out that the cholesterol content of the blood might be different in the early and in the later stages of gall-stone disease; at Leeds analyses had shown a high tide of cholesterol in the early stages, which more often came under observation in private practice, and that in the later stages, so frequently seen in hospital patients, there was hypocholesterolaemia. It would therefore appear that there is room for further information as to the cholesterol content of the blood in patients with gall stones.

### THE PROFESSION AND THE LAY PRESS.

For the last year or so the relations between the medical profession and its representative bodies on the one hand, and the newspaper press on the other, have been rather strained. There may have been faults on both sides. The newspapers want information and they want news. We do not recall the exact legal definition of "news" in relation to the Copyright Acts, but, at any rate in the view of the news editor, anything that did not happen yesterday is not news. That part of the matter we may leave aside. There remains the subject of information. We do not doubt that responsible members of the journalistic profession desire to obtain correct information about health, as about other matters. The medical profession has a great and, as we hold, well founded objection to anything that savours of self-advertisement; it therefore looks with a critical eye on signed articles on medical subjects in the newspapers. The journalists just now are making efforts to organize themselves as a profession, and are finding, like other professions, including the medical, that it has a tail. At present the tail has too much chance of wagging the dog. The medical profession, however, has got further in preventing its tail wagging the dog than have the journalists. None of us desire that the rift between the profession and the newspapers should continue, much less that it should widen. No doubt the competition among newspapers is very keen, but a good reputation can only be obtained by a journalist and by a newspaper if they contrive to present the public with trustworthy information. That, without question, is the object of all responsible journals and journalists. The differences with the medical profession have been caused by want of agreement as to how the information should be supplied. It cannot be by the method of a penny in the slot, and the greater part of what the medical profession has to say to the public can only

be issued after the substance and form have been carefully considered. We do not want our tail to wag us, and as things are there is a risk of this happening.

The question then is, how is authentic medical information to be supplied to the newspapers? The answer is not easy. *The Times*, in an anticipatory leader on Monday, said that "The last thing which any responsible newspaper desires is to serve the interests of a charlatan or a professional man who has so far forgotten his honour as to seek mere self-advertisement." But it tells us that the medical profession must not shut its eyes to the needs of the world in which it lives. We altogether reject the suggestion that the medical profession does shut its eyes to the needs of the world in which it lives, or, rather, of which it forms a part. It is very anxious to meet these needs and reform defects. To take the British Medical Association alone, we may remember how from its earliest days it took up the reform of the Poor Law and achieved much; but such work is long, and there is only now a hope that Mr. Neville Chamberlain will put the coping-stone on the edifice the foundations of which were laid by members of the medical profession. So, again, with public health, the Association has consistently and for more than half a century advocated reforms, some of which have been carried out with two results at least—namely, that disease has been diminished, and the everyday health of the people vastly improved. Incidentally, it encouraged and helped Parliament to pass Medical Acts to enable the public to distinguish between the trained and the untrained practitioner of medicine, with very great benefit to the public. By its efforts mainly came about the system of supervising the health of school children, and of curing and checking remediable defects. To it also is due in large measure the whole system now enforced by Parliament for the control of tuberculosis, and quite recently it has been concerned with the organization and extension of voluntary hospitals. All this work—and we have chosen only a few examples—has been altruistic, and has been done because the members of the profession, individually and collectively, are good citizens. Still, eaten bread is soon forgotten, and the question to-day is how to satisfy the legitimate demands of the press for trustworthy information.

Sir Thomas Horder, in his address to the St. Pancras Division of the British Medical Association (published in full elsewhere in this issue), has gallantly stepped into the breach, and though his solution is not complete it is evidence of goodwill. He takes care to enumerate some of the principal agencies for the dissemination of information already in existence; he mentions the Ministry of Health and the valuable essays specially addressed by Sir George Newman to the public. He might have said that excellent work of the same kind is being done throughout the country by the public health service, whose members are not slack in giving the public information whenever occasion serves. He might have mentioned also the medical press and its diligence in supplying trustworthy information which, through the public health service and through the clinical practitioner, finds its way to communities and to individual members of the public. But he recognizes that the newspaper cannot be expected always to wait for these considered pronouncements, and he suggests that the interests of the public would best be served by all articles and paragraphs on health subjects being controlled by experts whenever they deal with actual diseases and their treatment. He would have a committee of

experts and laymen to "vet" such articles before publication.

At the conclusion of the discussion which followed Sir Thomas Horder's paper the meeting, which was so large as nearly to fill the Great Hall in the Association's House, adopted without dissent the resolution moved by Sir Thomas Horder and set out in full at page 169 of the SUPPLEMENT. The resolution affirmed that the dissemination of news on health topics should be encouraged; that the actual medical instruction published might well be controlled by a representative body; and that editors of newspapers should not ask men in private practice to write articles under their own name. The difficulty arises with regard to the second clause, and we shall be glad to learn the opinion of those who control our lay contemporaries on it. It shows, at any rate, as we have said, evidence of goodwill, and ought to still the foolish accusation that the medical profession does not desire the public to get its information from the most reliable sources.

#### THE PRESIDENT OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

WHEN the Royal College of Surgeons arose upon the ruins of the Company of Surgeons of London its outlook was not much widened by the enlargement of its range of action. For a long time it remained, in practice if not in name, only a London institution, but after the establishment of the Fellowship in 1843 a gradual change came about. For the last fifty years or so the Council of the College has been strengthened by the presence of provincial Fellows among its members, who have generally been distinguished and progressive surgeons. Circumstances have greatly changed in surgical consulting practice in the last half-century, and it would be well if a greater proportion of the seats on the Council of the College were occupied by provincial Fellows, with the consequence of the chair being more often filled by one of their number, for a healthy decentralization of the practice of operative surgery, as well as of medicine, has followed on the foundation of the provincial universities and medical schools, so that the well-to-do need no longer come from the country to London for the best advice and the best operative skill. Up to the present time, however, we believe that no provincial surgeon has held the office of President, but now Sir John Bland-Sutton has been succeeded by one who is mature in reputation and can be trusted to do equal honour to the College and to his own University of Leeds. Sir Berkeley Moynihan's brilliant achievements in surgery are so well known as to need no particularization. Countless sufferers from dangerous abdominal disease owe him debts too great for payment, while his reputation in general surgery is only dimmed by the brilliance of his work in the hepatic region. If any proof were needed that there are exceptions from the scriptural saying that a prophet is not without honour save in his own country, the proceedings at Leeds on October 6th would furnish a striking example. Indeed, we think that, in these days and in this country at any rate, local patriotism and rivalry sees to it that the generous appreciation of the citizens of our great industrial centres should not be hindered in any way. The Corporation of Leeds did honour to itself, the University, and the medical profession in the person of Sir Berkeley Moynihan by presenting him with the freedom of the city. The ceremony was conducted with all the state and formality which befits such an occasion. The presentation of the freedom of the city to Sir Berkeley and six other living Leeds worthies marks the celebration of the tercentenary of the incorporation of the city. The casket in which was enclosed the illuminated scroll recording the gift of the freedom to the distinguished

surgeon appropriately bore a representation of a bust of that great Leeds surgeon, and father of the medical school, William Hey, whom Sir Arthur Keith, in his *Menders of the Maimed*, justly honours as the first to recognize the true nature of internal derangement of the knee-joint, and the first to treat it successfully by manipulation founded upon exact knowledge, in place of the haphazard methods of the bonesetters, to whose tender mercies the sufferers from this injury had heretofore been left. The new freeman of the city of Leeds is a worthy successor of Hey and of the other distinguished men who have adorned that Yorkshire medical school and infirmary. One of the other recipients of the same honour on the same day was Mr. Charles Lupton, who has been a member of the board of the Leeds General Infirmary throughout the whole of Sir Berkeley Moynihan's connexion with it, and was for over twenty years its chairman.

#### SERVICE MEDICAL OFFICERS IN PEACE TIME.

THE presidential address to the War Section of the Royal Society of Medicine was delivered on October 11th by Group-Captain Henry Cooper, D.S.O., R.A.F., who discussed some of the wider aspects of service medical work. The chief task of members of the War Section, he said, was to thrash out during peace time all questions open to debate which could affect the conduct of their affairs in future war, but to that end they had a double line of interests to follow. The first and more obvious was the observation of the health of the three fighting services and the maintenance of the highest degree of physical and mental efficiency. The second was a consideration of the forces which would be placed under their charge in the event of war; for the personnel now serving was but the nucleus of the forces which would be called into being in a great emergency. The discussions in the Section should have relevance to these future potential forces as well as to the stock—that is, the existing services—upon which those forces would be grafted. The general responsibility for the maintenance of national fitness was vested in the Ministry of Health, and whilst it was not possible or desirable for officers of the services to trespass upon the Ministry's sphere of activity, their interests were very closely bound up with the general question of national fitness. The consummation which they desired was to have a nation in which the principles of hygiene were thoroughly understood and universally practised, so that when vast numbers of men were mobilized for national service the rejections on account of unfitness, the necessity for hygienic instruction, and the dangers of epidemic disease, would all be reduced to a minimum. He thought it would be useful for members of the War Section to participate in discussions with other sections, and he suggested a number of subjects, such as preventable deformities, the early effects of middle-ear disease, the preparation of drugs and dressings in forms suitable for emergency and field work, the preservation of efficiency in tropical climates, and the early diagnosis of active service neuroses as a check on their development, all of which had an interest for other sections as well. He had frequently heard officers complain that in service life there was a lack of professional work and a consequent tendency to become rusty. But the service medical officer who thought that his whole work began and ended with the letter of the law as laid down in the King's Regulations was bound to sink into a narrow groove and to become almost mechanical in the execution of his duties. "The groove and how to keep out of it" would be a good theme for an appendix to a medical officer's handbook. Officers could do much in that sphere where service work bordered on the work of the civil profession. A closer liaison should be cultivated between men in the service and the men in civil practice. It should be

the desire of every medical officer, wherever stationed, to get into touch with the local civil medical men, and to attend, if his service duties permitted, the meetings of the local Branches or Divisions of the British Medical Association. He thought (and we are sure he is right) that if the point were put to them such Branches and Divisions would be glad to have an occasional paper by an officer of the service, and in the discussions following other papers of primary interest to civil practitioners the service officer could often take a useful part. A large number of civil practitioners had seen service, and they with others qualified later would flock to the service again in any great emergency, so that it should not be very difficult to enlist and retain their sympathy. They were all working for the same end—namely, an A1 population. Group-Captain Cooper went on to remark that the interests of the service officer followed the whole course of human life, from infancy up to military age. He, too, like his civil colleague, had an interest in the eradication of hereditary diseases and inherited susceptibilities; and one matter on which liaison with the civil medical authorities was very necessary was with regard to the reduction of the incidence of venereal and tuberculous diseases and the control of men suffering from these diseases when they passed out of the forces into civil life. The service officer was interested in questions of maternity and child welfare; it was well for him to follow also the measures adopted for the supervision of the health of school children and for ensuring the health of adults of service age. Movements for the provision of recreation grounds, for example, for the supply of good food, for better housing and sanitation, for the control of tuberculous disease in cattle, for the extermination of vermin, should all have his keen sympathy. The numbers of medical officers of the services were not very great, but the men were scattered all over the empire, and were moved frequently from one place to another. Wherever they went they should be eager to make and retain the friendship of the civil practitioners. For the education of the service officer himself frequent association with members of the civil profession would be of inestimable value, and he desired to impress on the young officer particularly the need for greeting his civil brethren with the hand of friendship, and so to soften the necessary formalities of service correspondence.

#### PILING OSSA ON PELION.

ON September 26th, 1925 (p. 581), we published a note on Memorandum 37/T of the Ministry of Health, which set forth the duties of chief administrative tuberculosis officers of local authorities in filling up four tables prescribed in the memorandum. On December 18th Circular 640 invited local authorities to make returns on these tables for the year 1925; but the duty was not to be made obligatory until the end of the present year. A number of returns for 1925 have been received by the Ministry, and from these it has become clear that misunderstandings have arisen as to the kind of matter to be entered in the four tables. Consequently the Ministry of Health has issued to county councils, county borough councils, and tuberculosis joint committees (England) Circular 726 and Memorandum 121/T. The latter is a memorandum on the preparation of annual returns under Memorandum 37/T. It appears that some tuberculosis officers began by mistaking a dato in Item 1, and then failed to appreciate that in Table I  $D = 1 + (A + B + 2) - (C + 3 + 4)$ . Further confusion arose between "new cases" and "contacts," which are intended to be mutually exclusive. Persons suspected to be suffering from tuberculosis, and attending the dispensary of their own accord or referred by a private medical practitioner, may give a history of previous contact with a known case of tuberculosis. They are not "contacts" for the purpose

of Table I, but should be regarded as "new cases" and recorded under A. Difficulties arose about directions given in footnotes to Table I; so that "observation cases" which were diagnosed definitely later in the year got into the wrong category, and "lost sight of" cases seem to have become confused with "observation cases." Sometimes also patients who returned after being "lost sight of" got into the wrong category as "new cases." The term "lost sight of" seems to have caused a great deal of trouble, perhaps because the memorandum admits that it includes cases to which "the expression may not be strictly appropriate." Thus persons seen only once in consultation, or admitted to an institution otherwise than under the tuberculosis scheme, or ceasing to avail themselves of public medical treatment, are officially "lost sight of," however insistently they may otherwise obtrude themselves on the official eye. At this point the new memorandum introduces what we cannot but think to be a dangerous precedent. If the tuberculosis officer finds that these categories of persons amongst the "lost sight of" are in high proportion, there is no objection to his showing such cases in a footnote as "Not requiring or desiring public medical treatment." But they must be included in the total under Item 3. We fear that footnotes will give the really earnest tuberculosis officer a vast field for his energy. In paragraph 10 of the new memorandum the word "consultation" is defined. It is not necessary for the general practitioner referring the case to be present at the examination; it suffices for the tuberculosis officer to give the practitioner a report in writing. In Table II the expression "beds available" has sometimes been taken as meaning those available in the authority's own institutions; whereas an average of the beds taken as required in outside institutions, but not definitely retained, must be included. From this table also patients sent to the institutions by other local authorities must be excluded. In Table III a patient multiplies himself. If he has been discharged from institutions three times in one year he becomes three patients. But if he has only been admitted for a short period, say, twenty-four hours, for some special purpose, such as x-ray examination or pneumothorax refill, he ceases to exist officially, but is allowed the grace of appearing in a footnote. An "observation case" in an institution has the privilege of being two patients during one course of treatment, and appearing in Table II both as an "observation case" and as a "patient." In drawing up Table III the Ministry unfortunately forgot the possibility of an "observation case" dying in an institution; but at this stage in the memorandum it has been discovered that a footnote solves all difficulties. Conundrums such as whether a Class T.B. minus patient who becomes a Class T.B. plus patient in an institution can be transferred from one class to the other in Table III, which asks for classification on the condition on admission to the institution; and whether a person admitted to public treatment as a child, and continuing as a child for Table IV, should be counted as an adult in Table III if admitted to the institution after reaching the age of 15—to these riddles the Ministry answers Yes. It appears that in some areas doubtful cases are kept under observation for long periods. However useful this may be from a clinical point of view, officially it is disturbing. Consequently the rule should be to complete the initial examination within a month, to watch for evidence of the disease for another two months, and then to enter a provisional diagnosis of "not tuberculous," cross the case off the register, and include it in heading C (b) of Table I. The patient should be told to present himself for re-examination if any suspicious symptom arises; but if he reappears during the same year he need not be counted as a new case unless evidence of the disease is found. The following year, however, he becomes a new case even if free from the disease

—an interesting settlement of the problem, "When is a 'new case' not a 'new case'?" After all these explanations it is not surprising to learn that the returns for 1925 show that in many areas the records of work done are altogether inadequate, while in others the methods of collating the information required for the returns is unnecessarily cumbersome. It is satisfactory, therefore, that the department has prepared a form of dispensary card register and a form of dispensary work sheet which, it is hoped, will provide all the information necessary for completing Tables I, II, III, and IV, and at the same time give other useful information to local authorities. A statement is issued to tuberculosis officers asking for samples, explaining the use of the card and work sheet; and with this at hand it is possible that tuberculosis officers will not require further memorandums explanatory of memorandums. There are several possible explanations of all this pother. Either the Ministry of Health has not clearly in its mind the objective at which it aims; or it is not clear about the methods it proposes for attaining that object; or the intellectual standard of the tuberculosis officer is not equal to the objective or the methods of the Ministry of Health. Although we shudder at the thought of inviting further memorandums, perhaps it might be well if the Ministry would from time to time state briefly what it hopes to achieve through this accumulation of data on tuberculosis. In the meantime we can, from experience, sympathize with the Ministry on the last paragraph of its Memorandum 121/T. "Many of the returns for 1925 show a failure to secure adequate checking of the figures and agreement of totals. In making statistical returns it is of course essential that proper attention should be given to these points." Tuberculosis officers are not the only persons who fail to give this attention.

#### EDUCATION IN ENTOMOLOGY.

At the International Congress of Entomologists held at Zürich last year Dr. H. S. Fremlin, of the Ministry of Health, presented a short paper pleading for a more widespread knowledge of entomology.<sup>1</sup> He urged the inclusion of this subject as part of the regular school curriculum and as a separate subject for those who may offer themselves as candidates for degrees in science. The paper is interesting in bringing forward examples of the ravages which insect pests may effect in agriculture and other industries, and also as agents in the causation of disease. Among the examples he adduces of the former are the wholesale destruction of forests in Europe and America by the nun moth and the gypsy moth; the former is so numerous that, after being blown out to sea by a hurricane, "when washed up by the tide, their dead bodies formed a wall six and a half feet broad and six feet high which stretched for many miles along the shore." Again, the winter moth may destroy whole crops of fruit trees in one year and so enfeeble them that the succeeding year's crop is negligible; finally, as a sea pest is mentioned the larva of *Callidium*, which is so voracious that it may seriously damage underground cables covered with creosoted cedar and lead plate. The author is not quite so happy in the examples he gives in the realm of medicine. Thus, he speaks of mosquitos as "carriers" of malaria and yellow fever, and the house-fly as a "carrier" of typhoid fever. The latter is not a carrier in the accepted sense of the former, but a mere mechanical transmitter. Further, the man in the street reading this paper would be led to think that Sambon had solved once and for all the problem of the etiology of malignant tumours by incriminating the *Gongylonema*. It is essential that a paper written for such a definite purpose as this should be as free as possible from mistakes

and should avoid hyperbole. To state that "nearly all tropical diseases are due to parasites," and that recurrent fever is due to fleas, are errors of fact. Speaking of education in entomology, the author mentions collections of insects by pupils of Bordeaux schools, and the international corporation in Holland for combating plant diseases and insect pests, but no mention is made of the Imperial College of Entomology and the Imperial College of Science, nor of the fact that all British practitioners intending to work in the tropics are advised to take the course and pass the examination for the Diploma in Tropical Medicine and Hygiene (candidates for Government medical appointments are compelled to take it), and that special courses in entomology, theoretical and practical, comprise an integral part of the curriculum. It is suggested that there should be established an entomological council, with an expert in each order of insects, to whom reference could be made for information and advice, and on the council there should be "a chemist, a botanist, a medical man, a veterinary surgeon, and a zoologist." Most people are aware now that the staff of the British Museum (Natural History) are always ready to do all in their power to identify specimens and to give advice to those who ask. The paper, however, will have done good service if it stimulates the laity to regard insects, not as mere nuisances, but as actual menaces to the health and prosperity of the people, dangers which can, in part at least, be averted by attention to measures of hygiene and cleanliness, assisted by knowledge of the life-history of these insect pests.

#### WITCHCRAFT.

In a leading article (August 14th, p. 311) on the celebration in 1928 at the Royal College of Physicians of the three hundredth anniversary of the publication of William Harvey's great treatise *De Motu Cordis et Sanguinis*, we referred to the part which he took in securing the acquittal of the survivors of the Lancashire witches who were brought up to London for examination. From the evidence quoted by Dr. H. A. Clowes in an interesting letter which appeared in our columns on September 18th (p. 543), it seems that Harvey's part in the matter was probably only that of an *amicus curiae*, for he did not sign the report, and the actual physical examination was carried out by well known surgeons. But the note by Dr. Letitia Fairfield, which was quoted in our annotation "Autopsy of a 'familiar'" (October 2nd, p. 610), gives reason to suppose that he had previously shown excellent common sense in his dealings with another so-called witch. The subject of witchcraft has been dealt with in a popular manner in a book by Mr. J. W. Wickwar which appeared last year<sup>1</sup>; in it he has collected records of many epidemics of witch hunting and judicial murder in our own and other countries, including those in New England in the seventeenth century. The story is a terrible record of credulity and of the awful ferocity which may be bred by fear, especially when it is helped by fanaticism. In this country the last trial for witchcraft was held in 1720, and the Act of James I under which proceedings were taken was repealed in 1735; the last severe outbreak of wizard hunting had, however, ended in 1677, when Matthew Hopkins, the self-styled "Witchfinder General," was responsible for 260 indictments in the counties of Essex and Suffolk, the greater number of which, according to Mr. Wickwar, terminated in executions, including that of the vicar of Brandeston in Suffolk, a blameless old man. Hopkins at last was hoist with his own petard, and was himself hanged in 1647 as a wizard. *O si sic omnes!* but such poetical justice was by no means common. Cotton Mather, the Congregational minister of Boston, Massachusetts, died quietly in his bed, and probably

<sup>1</sup> *The Necessity for More General Education in Entomology.*

<sup>1</sup> *Witchcraft and the Black Art.* By J. W. Wickwar. London: Herbert Jenkins, Ltd. (Cr. 8vo, pp. 320. 8s. 6d. net.)

never had a qualm of conscience on account of the many innocent people he had hounded to a painful death. Terrible as the British and New England record is, it is nothing to the holocaust of victims on the continent of Europe. Mr. Wickwar tells us that in Lorraine alone in the sixteenth century there were nine hundred convictions and executions for sorcery in fifteen years, and that in Germany between 1610 and 1660 there were over 100,000 convictions. The late French Academician Maurice Barrés stated that at one time certain villages of the Eifel district of the Rhine valley were depopulated by executions, so that not more than two living persons were left in each.<sup>1</sup> One remarkable fact which appears in all these persecutions is the tendency among certain accused to plead guilty, and to be proud of their supposed evil-doing. We could wish that Mr. Wickwar had given some of the authorities for his statements, for it is difficult to accept one or two of them.

#### EQUINE EPIZOÖTIC LYMPHANGITIS AND HUMAN HISTOPLASMOSIS.

Epizootic lymphangitis is a highly contagious disease of horses which runs a chronic course, attacking principally the superficial lymph vessels and the mucous membranes, where it causes purulent inflammation. It spreads to the associated lymph glands and produces a characteristic bead-like thickening of the lymph cords. As a rule the internal organs are not affected, although occasionally lesions are found in the lungs and intestines. The cause of the disease is the *Cryptococcus farciminosus*, which seems to gain entry through open wounds and abrasions. The disease is usually confined to the horse and his relations, but at least three cases have been reported in man, one of the victims being a French veterinary surgeon and another a farmer, both of whom had received the infection from affected horses by inoculation. The disease in man is not very serious, though the abscesses which form heal with difficulty and recurrences are common and may be accompanied by fever and general weakness. The cryptococci, which are found in the pus, are round or oval bodies with a double contoured membrane. They reproduce by budding, and are generally classified with the yeasts. They superficially resemble Leishman-Donovan bodies, which, it is interesting to note, were recorded for the first time from the horse by Richardson only last year.<sup>2</sup> It has recently been pointed out by Ota<sup>3</sup> that the organism is not a true yeast, but one of the fungi imperfecti, and should be transferred to the genus *Grubyella* among the *Hypomyces*. Its main interest to medical men, however, does not lie in the possibility of its transference to man—although it is probably more frequently transferred than the published records indicate—but rather in its close relationship to the *Histoplasma capsulatum* of Darling, who, in 1906, found in three human cases in Central America a new parasite which he described under this name; a fourth case has recently been reported by Riley and Watson.<sup>4</sup> The organism was at first regarded as a protozoon somewhat resembling leishmania, but differing sufficiently to merit being placed in a new genus, and the disease was termed "histoplasmosis." It has recently been shown that the organism is really a cryptococcus, but it has not yet been conclusively proved that it is the same species as causes epizootic lymphangitis. In none of the four cases previously recorded was there any history of contact with affected animals, and, indeed, there are no authentic cases of the disease occurring in horses in Central or North America; what was considered in the past to be epizootic lymphangitis in America has been shown to be really sporotrichosis, another equine disease which is

occasionally transmitted to human beings. Moreover, in histoplasmosis there are well defined internal lesions which are never found in the equine disease. On the other hand, the disease in man is so uncommon that there can be no doubt that some animal reservoir must exist. What this animal is is a problem which still awaits solution, and with it will be solved the mode of infection of human beings with an uncommon but serious disease.

#### ALCOHOLISM IN CLASSICAL ANTIQUITY.

At the first meeting of the session of the Society for the Study of Inebriety, held in the rooms of the Medical Society of London on October 12th, Dr. J. D. Rolleston delivered an address on alcoholism in ancient Greece and Rome. He remarked that as the scientific study of inebriety dated only from the middle of the nineteenth century, very little was to be gleaned from contemporary medical writers as to the prevalence and effects of alcoholism in classical antiquity. The chief sources of information are the poets, especially the gnomic writers, such as Theognis; the satirists, including Horace, Juvenal, Martial, Lucian, and the Greek Anthology; philosophers and moralists, such as Plato, Plutarch, and Seneca; and most of all the two encyclopaedic writers, Pliny the Elder and Athenaeus. Though there is some indication of the existence of chronic alcoholism, as is exemplified by passages in Pliny and Seneca and in the lives of certain individuals such as some of the Roman emperors, alcoholism in classical antiquity was mainly of a convivial character, and industrial alcoholism, apart from that associated with prostitution, was unknown. Dr. Rolleston quoted several passages from the classical writers dealing with the dysgenic influence of alcohol and other evil effects of drink on the community and the individual, especially the relation of inebriety to insanity, crime, and poverty, and the measures, often of a fanciful character, recommended by the ancients for the prevention and treatment of drunkenness. In conclusion, Dr. Rolleston showed that the alcoholism of classical antiquity differed from that of to-day by its predominance among the upper classes, the lack of legislative control, the absence of distilled liquors, which were not introduced until the fifteenth century, and the non-existence of syphilis, which in modern times was often contracted under the influence of alcohol, and was liable to run a severe course in alcoholic subjects.

#### DOSAGE OF ULTRA-VIOLET LIGHT.

For some time past the ever-increasing number of medical men actively engaged in radio-therapeutics have felt the need for a practical method of measuring the dosage of ultra-violet light. It must be remembered that not only has every patient a different susceptibility to the effect of these rays, but that the many varieties of lamp now on the market differ considerably both in the quality and quantity of the rays they emit. Not only that, but in course of use the output of all lamps falls off, in some cases slowly, in others more rapidly. To test the personal idiosyncrasy of the patient, which should be done in every case before beginning treatment, the only practical method is to expose a series of small areas of skin, each for a certain number of minutes varying from one to ten, and to note the result. This precaution will prevent a serious overdose being given at the outset of treatment. Fortunately, the consequences of an overdose of ultra-violet rays are not to be compared in seriousness with those of an overdose of x rays, but a painful sunburn is an unsatisfactory way of introducing a new treatment, and creates an unnecessary prejudice in the patient's mind. For testing the output of the lamp providing the rays many methods scientifically sound have been devised, but in general they are too

<sup>1</sup> Le Génie du Rhin, *Revue des deux Mondes*, 1921, vol. 61, p. 20.

<sup>2</sup> *Trans. Soc. Trop. Med. and Hyg.*, xix, p. 411.

<sup>3</sup> *Ann. de Parasit.*, 1925, II., p. 51.

<sup>4</sup> *Amer. Journ. Trop. Med.*, 1925, p. 271.

cumbrous for use in practice. One is based on the power possessed by ultra-violet rays of killing infusoria which are exposed in a cell of standard thickness, and the dose is expressed as so many I.K. units. Another is based on the speed with which the rays decompose carbon tetrachloride with the liberation of free chlorine, but both these are unsuitable for medical men in practice. What is really needed is a pastille which will measure ultra-violet light by gradual change of tint in the same way that the well known Sabouraud pastille measures the dose of x rays. It is possible that this need has now been met by the Levy-West ultra-violet pastilles which have recently been introduced to the profession by Arnold and Sons. These are placed on the patient's skin, and gradually turn colour under the influence of ultra-violet light. They are said to be insensitive to visible radiation and to heat. A tint card is provided with them showing the tints indicating units of dosage from one to twelve units, and all that is necessary is to compare the tint of the exposed pastille with the standard tints on the card. One great advantage of using these pastilles is that accurate prescription is rendered easy. All that is necessary is to order so many units according to the Levy-West scale. These pastilles certainly deserve a trial.

#### LISTER CENTENARY CELEBRATION IN EDINBURGH.

A COMMITTEE has been formed in Edinburgh to celebrate the centenary of Lister's birth, and in view of the Annual Meeting of the British Medical Association in Edinburgh it has been decided to make the celebration coincide with it. Arrangements are being made to offer a prize of £25 and a gold medal for the best essay submitted on the subject, "The influence of Lister on the evolution of surgery." This prize will be open to medical students of any medical school in the British Empire and graduates of not more than one year's standing. A book dedicated to Lister's life and writings is being prepared, and will probably contain about two hundred pages of small quarto size. A public meeting will also be held, at which addresses will be given by Sir William Watson Cheyne, Professor Tuffier (Paris), Dr. Harvey Cushing (Boston, U.S.A.), Professor Caird (Edinburgh), and Mr. Hamilton Russell (Melbourne). A museum containing some of the more interesting relics of Lord Lister's life and work is being got together. This is as far as the plans have already gone. Further particulars will be published later.

#### ARSENIC IN MARINE CRUSTACEANS AND SHELL-FISH.

MR. A. CHASTON CHAPMAN, F.R.S., read a paper at the meeting of the Society of Public Analysts last week in which he produced evidence of the presence of compounds of arsenic in marine crustaceans and shell-fish. The amounts ranged from 10 to 174 parts of arsenic (as  $As_2O_3$ ) per million of the wet edible portions. Native oysters contained from 5 to 10 parts, and Portuguese oysters from 33 to 70 parts per million. In fresh-water fish, shell-fish, and crustaceans the amounts of arsenic ranged from only about 0.4 to 1.5 parts per million. The arsenic in the marine animals must therefore, it was concluded, be derived from the sea water, and Mr. Chapman has ascertained the amounts of arsenic in sea water from various localities. Potted and canned crustacea and shell-fish contained from 0.5 to 25 parts of arsenic per million. The arsenic in the urine of two experimental subjects was, after a meal of lobster, raised from the normal figure of about 1/200 grain per gallon to 1/2 grain in one case and 1/3 grain in the other. Mr. Chapman, with the help of Mr. H. Linden, extended his researches to copper and lead. With regard to copper, the results expressed in parts per million of the dried edible portion were that lobster contained 167, crab 130, and

whelks 115. The amounts of lead ranged from 5 (whelk) to 25.3 (lobster). Native oysters contained from 12 to 400 parts, and Portuguese oysters 10 to 307 parts of lead per million. Like the arsenic, these metallic impurities are probably derived from the sea water.

#### JOHNS HOPKINS SCHOOL OF HYGIENE.

THE new building of the School of Hygiene and Public Health of the Johns Hopkins University, which is to be formally opened next week, is an imposing fireproof structure occupying a dominant situation in North Wolfe Street, Baltimore, adjacent to the Johns Hopkins Hospital. It includes departments of bacteriology, immunology, chemical hygiene, medical zoology, physiological hygiene, vital statistics, epidemiology, and public health administration. The department of sanitary engineering is housed apart in the civil engineering laboratory of Johns Hopkins University in the Homewood quarter of the city. The new building has a basement and eight stories, one of which is mainly devoted to the administrative purposes of the school. The departments of epidemiology and public health administration are together on one floor. The remaining departments are self-contained, each on its own floor, with its own lecture rooms, laboratories, and animal house where appropriate. The laboratories, which are most completely equipped, offer special facilities for individual research. The animal houses, placed in a tier at the back of the main structure, are linked each to its own department by fireproof ventilated passages. Down to 1914 the teaching of public health in the United States was mainly carried on by the Massachusetts Institute of Technology and by various courses in medical schools. In that year a conference of leading authorities in public health was held to consider the question of the training of public health officials and other experts in sanitation. At the request of the conference Dr. W. H. Welch and Mr. Wickliffe Rose prepared a plan for an institute of public health, following on which the Rockefeller Foundation decided in favour of setting up such an institute at Johns Hopkins University. It was guided in this decision largely by reason of the facilities, organization, and ideals of the Johns Hopkins medical department. In June, 1916, the Foundation informed the university that it was prepared to co-operate in the establishment of a school of hygiene and public health "for the advancement of knowledge and the training of investigators, teachers, officials, and other workers in these fields." The university accepted the offer, and its board of trustees appointed Dr. W. H. Welch director. The school began its work in 1918. From 1918 to 1925 it occupied buildings on the site of the university, formerly used as physical and chemical laboratories. On the completion of the new building for the school in October, 1925, it came into occupation, but its ceremonial opening was postponed until now. The Johns Hopkins School of Hygiene draws its students from many lands, in both the new world and the old. The places of origin of those who were enrolled in its courses during the last completed academic year include England, Ireland, Ceylon, Brazil, Porto Rico, Panama, Siam, Germany, Italy, Holland, Hungary, Canada, Bulgaria, Jugo-Slavia, Spain, Japan, and China, as well as, of course, States of the Union.

THE Bradshaw Lecture will be delivered before the Royal College of Physicians of London on Thursday, November 4th, by Dr. F. G. Crookshank, his subject being "The theory of diagnosis." The FitzPatrick Lectures, on "Medicine in ancient Assyria," will be given by Dr. Arthur Shadwell on Tuesday, November 9th, and Thursday, November 11th. The subject of Dean Inge's David Lloyd Roberts Lecture, to be given on Friday, November 19th, is "Racial Degeneration."

## Opening of the Winter Session.

### THE PATHWAY OF OBSTETRICS.

*Inaugural Address at the University of Edinburgh.*

BY

R. W. JOHNSTONE, C.B.E., M.A., M.D., F.R.C.S.Ed.,  
Professor of Midwifery and the Diseases of Women.

[Abstract.]

PROFESSOR JOHNSTONE delivered his inaugural lecture, upon the "The pathway of obstetrics," on October 8th, in the music classroom of Edinburgh University. He began by saying that every student who exercised the gift of imagination must feel some peculiar quickening of interest when he approached the study of midwifery, for there was no sentient human heart that failed to respond to the thrill of this everyday miracle. The beginning and ending of things ever made a greater appeal than did the middle, just as sunrise and sunset inspired the poet to greater heights than did the glare of noonday. Birth and death, which formed the apparent beginning and the apparent end of life, excited a peculiar interest and a profound curiosity in everyone, no matter whether they were regarded from the spiritual, the philosophical, or the purely physical point of view. Students would feel that in midwifery they had a study which linked together all their medical and surgical studies in relation to the span of human life and gave them a coherence which elsewhere might be lacking. In this subject were interpreted in terms of medical practice the care of the infant, the prevention of diseases such as rickets, the hygiene of childhood, the proper supervision of the critical period of adolescence, all of which were directed to making the rising generation fit parents for their successors. These phases of practice were, indeed, in a very real sense, the earliest stages of the ante-natal supervision which was the crowning phase of modern obstetrics. Then came the actual obstetric attendance during the dangers of childbirth and the prudent guidance which restored the mother uninjured to her ordinary life, or, it might be, the gynaecological art which was called upon to repair inevitable damage. So this obstetric art went on from one generation to another in a cycle. Midwifery might be spoken of as consisting of a science and an art, the science being the collected knowledge of ascertained facts, while the art was the practical skill guided by that knowledge. In regard to midwifery, they had the curious paradox that while it must in the nature of things have been almost the earliest of all medical arts, yet so far as recorded medical history revealed, its science hardly began to grow until some two hundred years ago.

#### *The Dark Age of Midwifery.*

Midwifery was originally in the hands of the female sex, and the "medicine-man," priest, or physician, according to the state of culture reached, was never called in until matters were so grave that all help was practically useless. The effect of this almost exclusively female practice had been very far-reaching, and in the Dark Ages they found that the knowledge of midwifery had been almost totally extinguished. Accordingly, mediaeval midwifery formed a ghastly picture. William Clowes, the most distinguished English surgeon in the reign of Queen Elizabeth, had said that surgery was practised by: "tinkers, tooth-drawers, peddlers, ostlers, carters, horse gelders, and horse leeches, idiots, apple-squires, broom-men, bawds, witches, conjurers, sooth-sayers, and sow-gelders, rogues, rat-catchers, runagates, and proctors of spittle-houses." This was bad, but the worst phase of Renaissance medical practice had been that of obstetrics. In normal labour the woman had an even chance, but in difficult labour she was usually butchered to death if attended by one of the Sairer Gamps of the time or by one of the vagabond surgeons. In 1580 a law had been passed in Germany to prevent shepherds and herdsmen from attending obstetric cases, and the Renaissance pictures showed that the

lying-in rooms were crowded with people bustling in every direction and giving the general impression of all sorts of female fussiness.

In common with all other branches of knowledge, obstetric science had been stimulated by the invention of the printing press, although it did not keep pace with the growth of medical knowledge in general. There had been an actual prejudice against the learning and teaching of midwifery in these early days, and this must have persisted in a blatant form in Scotland as late as the end of the eighteenth century. Professor Hamilton, who occupied the chair at Edinburgh from 1780 to 1800, had spoken of the great service done by Professor Thomas Young, his predecessor, "by dissipating the prejudice which existed against the necessity of instructing midwives. Even they who pretended to the sacred name of philosophers joined in the prejudice. Dame Nature, they said, is the proper midwife, and nobody can be better qualified to attend to her dictates than Dame Ignorance."

#### *Advance of Obstetric Knowledge.*

Despite all handicaps, obstetric knowledge had slowly increased during the seventeenth and eighteenth centuries. Increased knowledge had tended to favour the handing over of obstetric cases to the trained male physician, and the increased experience in practical midwifery so gained by the male physician had tended to foster the growth of real science. This had only been achieved after a hundred years of wordy and acrimonious warfare, of which a faint echo could be perceived in the amusing description given in *Tristram Shandy* of the circumstances surrounding Tristram's birth. Much of the credit for overcoming this prejudice belonged to a Lanarkshire Scot, William Smellie, who had gone to London and become the most prominent obstetrician of his day—indeed, one of the most prominent obstetricians of any day.

One special fact which had done much to hasten the transference of obstetric practice from the midwife to the trained obstetric physician was the invention of the midwifery forceps by Peter Chamberlen, a London physician of Huguenot origin, in the end of the sixteenth century. In most cases Nature had ordained that the child should be born head first, but up to his time no method had been discovered of expediting the birth of the child in cases of delayed or obstructed labour which did not lead directly to its death through injury, or involved its being turned in the womb and extracted feet first. The latter operation, podalic version, had been known to the Greek and Arabian physicians, and had been rediscovered by the great French surgeon Ambroise Paré in 1550. Although it was still performed in some cases with the best results, it was a formidable proceeding in comparison to the application to the child's head of the forceps, which was the modern successor to Chamberlen's instrument. The significance of the discovery of the forceps had been, first, that it was an enormously important forward step, and secondly, that it had become manifest that the use of this beneficial instrument could not be entrusted to the hands of an untrained attendant. It had been a reproach, however, of the Chamberlens that the discovery had been kept a secret in their family for four generations, as a means of increasing their professional reputation and as a source of private gain. Consequently, the nature and construction of midwifery forceps had not become generally known until the beginning of the eighteenth century. From this time the science had begun to grow under the cultivation of men like Mauriceau and Deventer, Smellie, Charles White, Fielding Ould, and others.

Scotland, at the beginning of the eighteenth century, had been a very poor country, and the conditions for the development of scientific obstetrics were less favourable than in wealthier England. The great majority of the cases of childbirth were attended by midwives only, who were called "howdies," and these apparently had been devoid of any training in the science of obstetrics, while in

the more remote villages and districts the matrons had earned an honest penny by attending each other in their confinements, very much as the inhabitants eked out their livelihood by taking in each other's washing. As a result, obstetric disasters had been common, and in 1726 the Incorporation of Chirurgians of Edinburgh had decided that an organized effort to train women for the office of midwives should be made without delay. An important minute of the Town Council of Edinburgh, dated February 9th, 1726, effected the foundation of the first chair of midwifery in the world. The minute ran as follows:

"The Council having considered the petition of Mr. Joseph Gibson, chirurgion in Edinburgh, with a declaration under the hands of four doctors of medicine, setting forth the usefulness and necessity of instituting a profession of midwifery; as also an extract of an act of the Incorporation of Chirurgians, shewing their approbation of the qualifications and capacity of Joseph Gibson, one of their number, for teaching the said art and science; they were fully convinced that it would be of great use and advantage to institute this profession; and being well satisfied with the ability and capacity of the said Joseph Gibson to discharge that office, they were of opinion that the Council should nominate and appoint him to be Professor of Midwifery in this city and privileges, with power to him to profess and teach the said art, in as large an extent as it is taught in any city or place where this profession is already instituted; and that he should be rested with the same privileges and immunities that are known to appertain to a professor of midwifery in any other well-regulated city or place; but that it should be expressly provided that he should have no fee or salary from this city out of its patrimony or revenue on account of his said profession. And having likewise considered that many fatal consequences have happened to women in childbirth and to their children through the ignorance and unskilfulness of midwives in this country and city, who enter upon that difficult sphere at their own hand, without the least trial taken of their knowledge of the principles upon which they are to practise that art, and that it would be a good service done to the community to put a stop to such practice, in order to prevent such mischiefs in time coming; they were of opinion that it should be enacted by the Council that no person hereafter should presume to enter on the practice of midwifery within this city and privileges till once they present to the magistrates a certificate under the hands of at least one doctor and one surgeon, who are at the time members of the College of Physicians or Incorporation of Chirurgians of this city, bearing that they have so much of the knowledge of the grounds and principles of this art as warrants their entering upon the practice of it. . . ."

The City Fathers had not realized what an original step they were taking, for there were, as a matter of fact, no other such appointments in existence. The duties of Joseph Gibson, the first professor of midwifery, had been the teaching, not of medical students, but midwives, thus showing that the practice of midwifery was still at that date predominantly in the hands of midwives. Some thirty years after the foundation of the chair, Professor Thomas Young had given an unofficial course of midwifery for medical students concurrently with the instruction of midwives. He had also been the first to institute clinical teaching of obstetrics in Edinburgh, and he was permitted, at his own expense, by the managers of the infirmary, to fit up an attic room for four lying-in women or as many more as he could accommodate. This had been the origin of what ultimately, after many vicissitudes, developed into the Royal Maternity Hospital, erected in memory of Sir James Simpson. England had lagged far behind Scotland and the Continent, so that it could not boast a university professorship of midwifery, and, what was still more startling, until the Medical Act of 1866 it was unnecessary for the medical student to be qualified in midwifery before being registered as a practitioner. Gynaecology, as a separate branch of surgery, had been non-existent until about the time of Sir James Young Simpson, the sixth and most distinguished occupant of the Edinburgh chair. In 1809, however, thirty years before Simpson was appointed, an epoch-making operation had taken place in the backwoods of Kentucky. Edinburgh had a special godmotherly interest in it inasmuch as Ephraim McDowell, who performed this first ovariotomy, had studied at Edinburgh, and had been profoundly inspired while a student in this city by the great John Bell, who was then one of the most eminent surgeons of the day.

### Pioneers of Modern Times.

The additional factors which had been necessary to promote the growth of surgery and gynaecology to their modern dimensions had been provided respectively by Sir James Simpson when he discovered the anaesthetic properties of chloroform in his dining-room at 52, Queen Street, and by Pasteur and Lister in the discovery of bacteria and of the antiseptic method for combating their evil effects in surgery. A profoundly important step had been the discovery of the fact that what was known as puerperal fever was the same as the condition called surgical fever—namely, a condition of bacterial infection occurring in wounded tissues. Many names, such as those of Charles White of Manchester, Gordon of Aberdeen, and Oliver Wendell Holmes, had been associated with the idea of infectivity in puerperal fever, but its nature had been discovered and brought prominently before the notice of the profession by a Hungarian, Semmelweis, whose work had been supplemented by the discoveries of Pasteur and Lister. The lecturer referred to the activity in the chair of Sir Alexander Simpson, nephew of Sir James Simpson, and to Matthews Duncan, Milne Murray, and others of the Edinburgh obstetric school. With regard to Sir Halliday Croom, he said that no one he had ever known had shown such inspiring devotion to the teaching of his students. He mentioned especially the work of the late Dr. John William Ballantyne, who had been lecturer in midwifery to women students during Halliday Croom's tenure of the chair. Ballantyne had not been gifted with the talents which made a successful practitioner, but he had been endowed with what was more rare, the vision of the pioneer. He had founded what was practically a new branch of pathology—namely, ante-natal pathology—and for many years he had ploughed his lonely furrow through the arid wastes of this most obscure and difficult subject. Ultimately it had been given to him to recognize what might now be said to be obvious, but what perhaps for that very reason had not been observed until he pointed it out—namely, the possibility of preventing many of the accidents and complications of labour and of the diseases complicating pregnancy. He had been one of the small band who definitely started the new development of ante-natal supervision and thereby widened the whole conception of midwifery. Nowadays the ante-natal department was one of the most important parts of every maternity hospital, and there was no phase of obstetrics which had been more fruitful in good results in the preservation of both maternal and infant life. As a prophet, Ballantyne had been favoured by being allowed to advance some little distance into the promised land which his vision had described. But death claimed him while as yet the full fruits of his labours were still to come. It was a particular satisfaction that their own Royal Maternity Hospital, which was erected to the memory of Sir James Simpson, in gratitude for the immortal contribution which he had made to medical and obstetrical science, should now have, as a complementary part, a Ballantyne Memorial in an ante-natal department, which might confidently be stated to be second to none in the United Kingdom.

### THE FREEDOM OF MEDICINE.

Introductory Address at the University of Durham  
College of Medicine, Newcastle-on-Tyne.

BY

C. O. HAWTHORNE, M.D., F.R.C.P., F.R.F.P.S.

[Abridged.]

WHATEVER be the several stages you as individuals have reached in the undergraduate world, it is for all a common experience that your school days have ended; that you have entered as undergraduates in the life of a university; and that you are looking forward to the day when lecturers and examiners shall cease from troubling and, as you fondly imagine, weary graduates shall be at rest. Each of these three stages has, of course, certain features peculiar to itself, but, broadly speaking, it may be said that as you pass from one to the next you move into a widening area of personal freedom. You have now definitely reached the second stage.

*Freedom in Undergraduate Life.*

It is the youth who learns to obey that is the father of the man who is able to command. At the present moment you as medical students stand midway between these two terms. With the termination of school discipline you have stepped into the larger freedom of the undergraduate. Possibly, even yet, you may sometimes be more conscious of limitations than of liberties, and may complain of the irksome restraint of compulsory lectures and compulsory examinations. Nevertheless, the university gives you a wider freedom than the school, and this is true both of conduct and of opinion. The apprentice may now, as he will, be either industrious or idle, and this perhaps without any immediate reward or penalty, though sooner or later chickens come home to roost and acts carry their inevitable consequences. In the field of opinion, or at least in the expression of opinion, the undergraduate admittedly suffers some measure of restriction, more particularly in his contacts with examiners. The advantage of the last word in most questions rests with posterity; but this is not true of examinations. All the same, the atmosphere and influence of university life are towards the cultivation of a growing independence of judgement, the development of original views, and the assertion of personality. Especially valuable as educational agencies in these directions are the generous rivalries and loyal comradeships that you share with your fellows, the academic traditions that you inherit in common, and the activities and opportunities of your students' debating societies. In open controversy and criticism you are stimulated to think for yourselves, to advance arguments of your own, to contest the arguments of your fellows, and to cultivate ideas and the capacity of putting these into appealing and intelligible speech. The controversies may be fierce and the soft answer that turneth away wrath exceptional, but even in these asperities there is a training in the courtesies and proprieties of debate.

In short, the apparatus of a university has this purpose or end, to provide such a measure of freedom and such a degree of discipline that those who submit themselves to these opportunities shall be fitted for a still larger freedom and for a corresponding burden of responsibility. This ambition is not exhausted by mere technical efficiency, valuable and important as such efficiency necessarily is. To it must be added, by the deliberate cultivation of the faculties of observation and judgement, and by the voluntary practice of self-discipline, the development of a mental habit and outlook which applies its estimate of values to all departments of life. A university education is effected not merely, perhaps not mainly, by didactic instruction. Not less important is the agency which leaves the student a measure of freedom within which he may train himself and be trained by his fellows, and this in an atmosphere rich in the traditions of the past and keen with the questionings and the uncertainties of the present hour. My suggestion, therefore, is that in your university life, while there is still direction to which you must needs attend, and a series of tests to which you must needs submit, there is also an opportunity to train yourselves to use freedom both wisely and well, and thus to prove yourselves competent for a still larger liberty. More than ever before, your fates are in your own keeping, for the liberties you now enjoy as students of medicine and university graduates may be made, if you so will, an educational apparatus by which you may add to technical efficiency in your profession the virtues and advantages of the trained, the equal, and the philosophic mind.

*Freedom in the Practice of Medicine.*

And now, what is the larger freedom for which you are preparing? In what sense, and in what degree, will you enjoy individual freedom within the scope and function of medical practice? There is here, of course, a question of opinion and a question of action; and the proposition I wish to set up is that in both of these respects the medical practitioner is a free man. There are qualifications in fact, and to these I will allude in a moment, but in principle it is true, and we ought to be urgent to maintain it, that medicine offers a life where the individual judgement, the individual opinion, and the individual decision, are neither

enforced on the one hand, nor restrained on the other, by an arbitrary, or quasi-infallible, or executive authority. There is no voice to which you must needs give heed that can inscribe on tables of stone a series of medical commandments, or that can compel your subscription to thirty-nine or some other number of articles. Whether for good or for ill, the life offered by medicine is a life of intellectual liberty where every honest man may hold his own convictions, and express his own judgements, and follow his own policy; and this without fear either of authoritative censure or of official excommunication. However dignified and commanding certain professional organizations may be, none of them has the skill or competence to discharge thunderbolts against the practitioner who chooses to exercise his right of private judgement.

Now while this claim may confidently be made to-day, medicine is not without experience of a very different order. For centuries there was no liberty in medicine. On the contrary, there was a fixed and rigid orthodoxy from which any venturesome heretic dissented at his peril. Very substantial penalties fell on any innovator who ventured to question the medical scripture according to Galen as this was written in the second century of the Christian era. The doctors, in short, like the theologians, had a fixed and authorized code of doctrine and practice, and, again like the theologians, they were ready to "prove their doctrines orthodox by apostolic blows and knocks." But from this position, defined by authority, and from the sterile and stereotyped life and atmosphere which it produced, medicine has long since freed itself, though not without vigorous struggles and bitter controversies. To-day there are in medicine no orthodox opinions to which we must needs subscribe, and no compelling voice competent to define a creed or to enforce a method of practice. Over all this wide field it is for the individual to exercise his own judgement, to frame his own opinion, and to take his own decision. Such is the freedom, and, note also, such is the responsibility, to which you will be called.

*Restrictions on Liberty.*

It may, perhaps, be objected that this definition of individual freedom in medicine is an extravagant or exaggerated one. Can anyone reasonably say, it may be asked, that the individual medical practitioner is quite free from authoritative control, and is at full liberty to entertain any views that commend themselves to his judgement, and free also to apply these views in the conduct of his practice? The answer to these questions is decidedly in the affirmative, though this is not to say that such liberty ought to be exercised as a mere personal eccentricity, or as an expression of ignorant and obstinate self-will. On the contrary, in this field as in others, a man must be prepared to defend his judgement by reasons and to justify his actions by results. He is free but he is responsible. There are certain limitations, it is true, but these are imposed by reason and logic and common sense, and not by any artificial bond or arbitrary authority. The limitations are in the nature of things. Thus, manifestly, a medical man is not free to poison a patient with opium or arsenic and then successfully to plead that in his opinion this proceeding was in the interests of the community; or, alternatively, that though he had indeed administered the poison, the responsibility for dying must be placed upon the patient. Neither in law nor in morals can ignorance, or stupidity, or carelessness, exhibited in a responsible situation, escape its due penalty by an attempt to take sanctuary under the protecting plea of the right of private judgement. The civil or criminal courts of the realm would make short work of such simplicity.

Again, beyond the bonds and limits of the law there are certain conditions which exercise a common-sense, or, if you will, a moral influence on medical liberty. It is true that there are in medicine no orthodoxies to which the faithful must needs adhere. On the other hand, there exist naturally and inevitably a number of doctrines and practices widely or almost universally accepted, and built on a more or less prolonged experience. A general consent of this order is a fact of much moment, and especially for the younger members of the profession. What exists and seems to have been tested by time and by many observers

has surely a presumption in its favour. Beyond this admission, however, we must allow no restriction on liberty. No doctrine or practice in medicine, however ancient its lineage, however dignified its sponsor, or however favoured by the Fathers and Brethren, is or ought to be secure from critical or even destructive attack. The young practitioner may reasonably be expected to give some heed to the ancient ways, but the time may come when he refuses to walk therein and elects to challenge the accuracy or wisdom of the older guides. This is his heritage of freedom, and he can claim it without fear either of authoritative censure or of penal consequences.

#### *Independence and Authority.*

What I here claim, then, is that in medicine there is a free and open atmosphere for the man who has some new truth to teach, whether in the area of doctrine or in that of practice. Granted that he is of good faith, that his work is real and not pretence, and that he can give reasons for the faith that is in him, he will sooner or later command an audience and disciples. He may perhaps flatter the senior dovecots, not wholly to their disadvantage, for it is the duty, perhaps not always fulfilled, of those of us who feel in greater or less degree the chilling and numbing effects of years to keep an open mind, and indeed, an attitude of encouragement towards the independent enterprises of the younger, and, it may be, the wiser generation. There is no halfway house. Either men must be free to think and speak the thing they will, uncomfortable as this may be for established opinion, or they must be liable to control or suppression by authority. Medicine has had its experience of this latter discipline, and has definitely abandoned it as antagonistic, not merely to freedom, but also to truth. If your desire is for a life of mental calm, where "all things always seem the same"; or if you wish a path and conduct ever dictated by superior authority, you had better seek these soporific ambitions in some profession other than that of medicine. Do not indulge the vain hope that freedom and fixture may somehow be combined. But if, as I gather, your choice is for the open fields and the wide spaces of medicine, be not negligent of your heritage of freedom. It is well for you, even in early days, to recognize these liberties and to cultivate them, not merely with discretion but also with courage. Medicine does not desire disciples drilled to a mere mechanical response to the orders of the sergeant-major. On the contrary, individual initiative has here a full opportunity, and it is your duty and interest to take advantage of this position and to cultivate, as you may, independent thinking and personal originality.

To sum up my present point I would say: You are to succeed to a great heritage of freedom; in that freedom respect by all means the traditions of the elders; but let these neither overawe you nor dismay you, nor bind you to a mechanical and unthinking obedience. I add that the attainment of this personal capacity is not achieved except by unrelenting effort: he who would see with his own eyes must learn to look without the use of other people's spectacles. In medicine you have this freedom if you care to use it. Ill would it become me to preach from this place a revolt against constituted authorities. Within limits we must all submit. But let it be remembered that originality of view and independence of judgement are qualities which, apart from their interest to the individual who possesses them, have a high value to the community and to the race. There is a large field of opportunity for them in medicine.

#### *Freedom of Opinion.*

The claim, then, is for freedom of opinion. Let us be quite sure of the meaning of our terms. Opinion is a word in everybody's mouth, though often it means nothing more than a personal taste or prejudice or preference, or an echo from a printed page. Our friends and acquaintances for the most part have what they call their "opinions" on almost every topic. They may modestly confess that they know little or nothing about the subject, but they are more than ready to tell us what they think. Of these exercises the medical practitioner has indeed special experience. Now in medicine when we speak of "opinion" we mean

something precise. A medical or scientific opinion may be defined as a mental conviction resting upon an intelligible basis; it is a judgement, inference, or conclusion resulting from the consideration of evidence. This is the sense in which the practitioner forms and acts upon his opinion in any individual case, or in which he gives his assent to any general medical proposition. Hence, when we say that in medicine there is liberty of opinion, we mean a rational and ordered liberty, exercised not on mere inclination or whim or fancy, but exercised in accordance with the logic and teaching of evidence. Observe that this statement does not justify an opinion on the ground of its accuracy. So long as men are fallible they will make mistakes, due perhaps to incomplete knowledge, perhaps to inaccurate information, perhaps to imperfect reasoning. An opinion in the sense here defined is not always right, but it is reached by an orderly and reasonable route, and if it proves to be inaccurate the localization of the flaw can be determined when all the facts are known. On the other hand, a mere guess may be right, and this, indeed, is one of its particular dangers, for the arrival of the lucky chance is apt to lead the author of the guess, whether he professes a diagnosis or backs a winner, to imagine himself a very smart fellow, forgetful of the truth that "winning tricks is not always proof of good play."

But with these irregular and illogical methods we are not concerned when we set up a plea for liberty of opinion within the province of medicine. What we mean by such liberty is the right of any practitioner, unhindered by authority, to scrutinize and cross-examine any proposition, to collect his own evidence, to form his own conclusions, and to push these if he will against current doctrines and practices. Truth unfettered, and spelt with a capital T, is the sole aim of medical inquiry, whether this is directed to an individual clinical problem or to a wide and general proposition. The lawyer seeks, for truth according to a pre-determined standard and after having decided in advance what shall, and what shall not, be accepted as evidence, while for the ecclesiastic truth is already known, and the formal statements of it must neither be questioned nor challenged. But the doctor knows no such restrictions. He has to suffer much uncertainty and doubt, and is continually aware how scanty is his knowledge and how limited are his powers. On the other side of the account he has this advantage, that he is never under an obligation to pretend to know what he knows he does not know, or to profess a conclusion on inadequate evidence. I am not questioning the advantage, or even the necessity, in certain spheres of life of the closing of issues by a final and conclusive voice to which all must give attention. But in medicine there is neither a House of Lords nor a College of Cardinals, and it would be an ill day for medical science and medical practitioners, and for the general public, were any such organization called into existence.

Such, then, is the liberty to which you will be elected. It is not a riotous and tumultuous liberty. But it is a full liberty for honest work and for honest men. Admittedly it may be abused, and indeed few ambitions are easier than to be a successful medical humbug. Medicine offers two large opportunities—the opportunity to observe and to work, and the opportunity to pretend and to prance and to pose, this latter not without its rewards in the limelight. If the worker is to have the freedom that he needs, we must take our chance of the shams and simpletons. The good grain must be free to grow even though this means an opening for occasional tares. The claim therefore is, not that liberty carries no risks, but that it exists for those who have the courage to use it.

#### *Opinion and Action: The Human Factor.*

Perhaps it may be suggested that in a life where there is much liberty of prophesying, and where you may often be called upon to revise your conclusions and convictions, there cannot be much mental comfort. That is a perfectly fair comment, and for those for whom "there is no joy but calm" a medical career offers no inviting retreat. On the other hand, the consciousness of imperfect knowledge and of ignorance is a stimulus to initiative and enterprise and endeavour, and is it not largely in the

exercise of these activities that man gets in his life mental happiness and satisfaction? Again, there is room for the remark that to live among open questions and undecided issues is liable to weaken the power of decision and to paralyse the capacity for action. We must not deny that medicine is by no means free from issues on which a confident opinion in the present state of our knowledge is impossible. To halt between two conclusions is sometimes unavoidable, and when we don't know there is credit, and not discredit, in saying we don't know. But we must distinguish between academic reserve and practical action. The daily life of the doctor repeatedly presents situations in which decision and action are imperative, while a confident pathological interpretation of the facts is for the time being impossible. The doctor, in other words, has to meet emergencies which cannot await scientific discussion; his first charge (even more than the discovery of truth) is the welfare of his patient; and he may often have to act, and act strongly, on a mere balance of probabilities. Thus, while he learns that deliberate judgements and opinions must be based on considered evidence, he is taught equally that quick wits and resolve and courage and prompt action are essential in the practical business of life.

One other influence may be mentioned as tempering the mental questionings and debates of the medical atmosphere. It is that the doctor does his work not solely under the influence of the cold, dry light of scientific knowledge. Associated with this throughout is a consciousness of the mystery of pain and suffering and of the sense of tears in human affairs. There is a scientific problem to be contemplated at the bedside, and this has to be solved in accordance with the strict demands of evidence. But there is something more—the welfare, and even the fate, of one with whom we are conscious we share in greater or less degree a common lot. Human emotions and sympathies and hopes and fears and sufferings and endurance are facts not less certain than the branches of the femoral artery or the percussion limits of cardiac dullness, and the doctor has to study and weigh these agencies if he would be not merely a student of disease but also the stay and succour of the patient. While strict accuracy in observation and record are one influence in his life, not less real is the discipline which inculcates understanding and sympathy and helpfulness. Thus while the practitioner of medicine may, and indeed often must, in his quiet study dwell in the realm of philosophic doubt, equally in his active service he is stimulated to prove himself the prompt, the informed, and the sympathetic helper of those who in their sufferings and distress turn to him with confidence and hope.

What is the conclusion of the whole matter? That in the life offered by medicine there is freedom for honest work and honest thought; that this freedom necessarily implies a corresponding measure of personal responsibility; and that any undue tendency to mere academic debate is corrected by the demands of practical affairs and by the appeal and mystery of pain and the hazards of human life.

## RELATIONS OF MEDICINE AND DENTISTRY.

### SIR HUMPHRY ROLLESTON'S ADDRESS AT THE ROYAL DENTAL HOSPITAL.

At the Royal Dental Hospital of London School of Dental Surgery the scholarships, prizes, and certificates awarded during the winter and summer sessions, 1925-26, were distributed on October 4th by Sir Humphry Rolleston, Bart., K.C.B., Regius Professor of Physic in the University of Cambridge, who gave an address on the relations of medicine and dentistry.

Both medicine and dentistry, he said, had travelled far on their own lines during the last forty years, and had got into rather closer touch on their journey; but in the interests of each more intimate association was desirable. Not so long ago the bearing of dental disease and dental deficiencies on general medicine was regarded as mainly concerned with referred pain, dental headache, and the mechanical factor—namely, incomplete mastication and

the consequent swallowing of hard lumps of food. A great change was effected by the recognition of the etiological importance of dental sepsis in systemic disease. This advance was in the first instance the outcome of the patient investigations into the pathology of pernicious anaemia by William Hunter, who, in 1900, described oral sepsis; out of this grew the more expanded conception of focal infection, and its importance was certainly not underestimated now. The employment of x rays in examination of the teeth for apical disease had shown the close association of these lesions with rheumatoid arthritis, fibrositis, and allied conditions, which annually cost the nation three million weeks of lost work among the insured population. Not only had dental science done much for practical medicine, but advances in medical knowledge had thrown light on the causation of dental disease.

### Correlation of Dentistry and General Medicine.

Dentistry and its followers had a tendency, much more marked than in other branches of the healing art, to be isolated from general medicine and surgery. To some extent this might be excused by the contention that theoretically dentistry should be a prophylactic science and art, and if carried out in a perfect manner should prevent any medical or surgical complications. But it would be very long before this ideal could be realized, and its advent would be facilitated by a more intimate association with general medicine and surgery. While the dental out-patient departments of general hospitals nominally formed a connecting link, in ordinary hospitals they were almost purely treatment, not teaching, departments; and though the patients, of course, benefited, there had been little gain to the advancement of dental science and education. That there was a demand for dental schools in connexion with the general teaching hospitals had been proved by the success of the schools founded within the last forty years.

There were indeed good reasons for the close association of dental with medical schools. From the patient's point of view there was much to be gained by consultation, especially in cases on the border-line between dental and general medicine and surgery. The arrangements for treatment should be more intimately united. Beds should be provided for patients undergoing extensive extractions and operations on the jaws which might come within the province of the general surgeon, and could not be dealt with satisfactorily in the out-patient department; while patients suffering from complications requiring medical supervision should obviously be under the care of hospital physicians. The need for beds for dental patients had now been recognized by the Middlesex Hospital in the allotment of beds to its dental staff. In the interests of dental science dentistry must gain by correlation with other departments, and by the application of new knowledge primarily derived from workers in different lines of research, but nevertheless of far-reaching practical importance. Contact with physicians, surgeons, pathologists, bacteriologists, and biochemists should enable combined researches to be made into the influence of general disorders, such as those of infective, metabolic, deficiency, and endocrine origin, upon the teeth. Conversely there was still much to be done in critical investigation and accurate evaluation of the influence of dental disease and defects on the body as a whole. The Dental Board encouraged research and had recognized the principle of increasing the opportunities for correlation of dental with other branches of medical investigation by arranging for lectures on general anaesthesia during the past year. From the point of view of dental students, the opportunities of seeing the medical and surgical complications of dental disease and of becoming familiar with the general disorders which might cause dental changes were obviously provided in a general teaching hospital.

### Medical Qualifications for Dentists.

In other special branches of the healing art a good general knowledge of medicine and surgery, as shown by a qualification to practise, was a *sine qua non*. This was not held to be necessary in dentistry, and such a change might appear revolutionary. Revolutions, however, were often salutary, and were then called reforms. But a compulsory medical qualification for all dentists, however

advantageous theoretically, was undoubtedly open to serious objections. The practical objection of the increased expense and length of the curriculum necessary to obtain a qualification in medicine and surgery in addition to dentistry was difficult to meet without some modification in the medical and surgical requirements for this qualification by intending dentists; this, however, would be unsatisfactory, for any such concession would eventually defeat the aims of the change, and, indeed, would not be very different from the demands already made in some examinations for a dental degree. No doubt many dental students fully realized the great advantage of taking a medical qualification, and did so when this was financially possible. How those not so fortunate, though equally capable and deserving, could be assisted it was difficult to say. The objection that to require from those going in for a dental diploma an additional qualification in medicine and surgery would so diminish the number of qualified dentists as to be detrimental to the public interest was perhaps not quite so insuperable. Women had come into medicine, and after the war did so in such numbers that for the time being, at any rate, they were not so easily absorbed. In many respects they were well fitted for the dental profession, and by adopting it they might find a congenial career, and thus, to some extent, meet the demand for dental treatment.

It might be urged that dentistry was so special and so divorced from general medicine and surgery that it stood on a different footing from other specialties. But was it true that ophthalmology, laryngology, and otology

depended more closely on medicine and surgery than did dentistry? Ophthalmology also was a very special subject, and so much concerned with optics that opticians without any medical qualification abounded; but they were unquestionably handicapped thereby. It should be remembered that ophthalmology was evolved out of medicine and surgery, and so remained a member of the family, whereas, at any rate since the revival of learning in the sixteenth century, dentistry grew up independently, partly because of its own special technical demands, partly from the aloof attitude of medicine; it was therefore commonly assumed that they were essentially different. A break with this tradition would be in the best interests of dentistry; to go further, there could surely be no doubt that if and when a dental diploma or degree was made a post-graduate qualification, the status and the utility of dentistry would be much enhanced. At present (and the future might well see an increase in this direction) a number of dentists were also qualified in medicine with advantage to their profession and to themselves. At present this worked well, or without any manifest bad effect, but would it remain so? As time went on and fresh ideas and developments arose, especially in pathology, might there not be a more obviously and popularly recognized division of dentists into two grades—those with and those without a medical qualification? It would be an evil day for dentistry if this differentiation ever became analogous to that between ophthalmologists and opticians. This question of a combined medical and dental qualification would in time, no doubt, become one of practical politics.

## England and Wales.

### VITAL STATISTICS FOR 1925.

THE Registrar-General's *Statistical Review of England and Wales for 1925*, Part I, Medical, was issued on October 8th. It is an octavo volume containing 520 pages, and can be obtained from the Stationery Office in London, Manchester, Cardiff, and Edinburgh, or through any bookseller, price 15s. It is stated in the course of the review that the birth rate, which since 1920 has shown a continuous decline, was 18.3 per 1,000 persons living in the year 1925. This rate was 0.5 per 1,000 below that of 1924 and, excepting the war years 1917 and 1918, was the lowest recorded since the establishment of civil registration. The death rate was 12.2 per 1,000 and was equal to that recorded in the previous year, but was 0.6 per 1,000 above the rate of 1923, which was the lowest on record. The infantile mortality rate was 75 per 1,000 births and also equalled that of 1924, but was 6 per 1,000 above the lowest rate, recorded in 1923. The death rate from tuberculosis showed a further decline and was the lowest yet recorded; the mortality from cancer was the highest on record. The mortality from influenza showed a substantial decline compared with the previous year, while that from encephalitis lethargica was slightly below the high rate of 1924. The death rates from measles, scarlet fever, whooping-cough, and diphtheria were all above those of 1924. The mortality from enteric fever was the lowest on record, and for the first time the mortality of the two sexes was equal.

### RECONSTRUCTION OF THE LEAMINGTON PUMP ROOM.

Sir Kingsley Wood, Parliamentary Secretary to the Ministry of Health, formally opened, on October 9th, the Leamington Royal Pump Room, which has been reconstructed and modernized at a cost of about £15,000. In addition to natural saline baths, the special treatments offered by Continental centres can now be obtained at Leamington, including various electrical, galvanic, radiant heat, paraffin wax, and ultra-violet ray therapeutical procedures. Sir Kingsley Wood referred to the fact that spa treatment for rheumatism and allied complaints had been available at Leamington for more than six centuries, and he thought the time had come for British spa treatment to be made available for all classes of the community. He mentioned that at the recent annual gathering of the friendly societies it was decided to ask the Government

to include spa treatment as an additional national insurance benefit, and the Federation of British Spas had under consideration a scheme whereby they could treat about 30,000 people each year. He promised that careful and sympathetic consideration would be given to this scheme by the Ministry of Health. In supporting a vote of thanks to Sir Kingsley Wood, Dr. Fortescue Fox discussed the special characteristics of the saline content of the Leamington waters, and regretted the absence of facilities for systematic instruction in hydrotherapy in the universities and medical schools of Great Britain.

### PRESENTATION TO SIR JAMES BARR.

The annual inspection of the West Lancashire Voluntary Aid Detachment took place on October 2nd. Colonel Powell was the War Office inspector, and there was a good muster of V.A.D. nurses, who carried out various nursing operations in a V.A.D. hospital extemporized at the Liverpool Scottish headquarters. Sir James Barr, as county controller, was presented with a gold cigarette box inscribed: "Sir James Barr, C.B.E., D.L., M.D., for signal services in connexion with the V.A.D. of West Lancashire." Mrs. Tweedale of Rochdale, district lady superintendent, made a graceful speech, alluding to the untiring energy of Sir James Barr, and Mrs. Howard of Preston supported the resolution of thanks and appreciation accompanying the gift.

### SMALL-POX IN LONDON.

A woman resident in St. Pancras, who had been previously visiting Paris, was admitted to the Royal Northern Hospital in Islington, on October 7th, with an ill-defined rash. On the 9th she was isolated, and on the 11th she was diagnosed as suffering from small-pox by Dr. G. Clark Trotter, medical officer of health for Islington, and Dr. W. McC. Wanklyn of the London County Council Health Department. Her stay in Paris covered the period September 11th to the 24th, which was considerably later than that of the Willesden patients, of whom mention was made in our issue of October 9th (p. 660). The date of infection of the St. Pancras patient is believed to be between September 22nd and 24th. Inquiries are being made in Paris, but it has not yet been possible to trace the source of infection, which is presumably still active. It is, further, noteworthy that, although the type of small-pox at present prevalent in Paris is mild, this is not the case with the patients in Willesden and St. Pancras; in the last patient the rash is of the confluent variety.

## Scotland.

### OPENING OF NEW RADIOLOGICAL DEPARTMENT AT EDINBURGH.

H.R.H. THE DUKE OF YORK, on October 9th, paid a visit to Edinburgh, in the course of which he participated in various social functions, which included receiving the freedom of the city and the opening of a new department of the city gas works, which had cost a quarter of a million sterling. The visit commenced with the opening of the new radiological department in the Royal Infirmary of Edinburgh, which has just been completed. His Royal Highness and the Duchess of York were received at the Royal Infirmary by Lord Provost Sir William Sleigh, Sheriff Crole, convener of the Finance Committee, the Right Hon. Sir John Gilmour, Bt., Secretary of State for Scotland, and other members of the management and staff of the institution. The Lord Provost presided, and remarked that x-ray work had begun in the Royal Infirmary, Edinburgh, under Drs. Milne Murray and Dawson Turner in 1898. The first x-ray photograph had been taken on October 14th in that year, and in the course of the following year 600 x-ray examinations were made. The department then consisted of one room on the ground floor, and in these particulars a great contrast was presented by the present large department, and by the fact that over 23,000 examinations had been made during the past year. From 1909 the work had been carried on by Dr. Hope Fowler and Dr. Archibald McKendrick, until it had been decided to appoint for the present institution a whole-time radiologist, who would also conduct the teaching of radiology. Dr. Woodburn Morison had been appointed to this post, and at the same time had been made lecturer on radiology in the University of Edinburgh. Towards the construction of the building the Edinburgh Committee of the Scottish Branch of the British Red Cross Society had contributed the very handsome sum of £15,000, the total cost being estimated at £52,000. He desired to express the gratitude of the managers to Dr. Robert Knox of London, who had acted as honorary expert adviser in connexion with the scheme from its inception, and also to Sir James Hodsdon, who, as the convener of the Medical Electrical Committee of the Board, had devoted much time to supervising the erection of the buildings and the installation of the plant. The Duke of York, in declaring the department open, paid a tribute of praise and gratitude to the pioneers in radiological research. He reminded his audience that the Royal Infirmary was maintained entirely by voluntary contributions, and expressed his gratification that the total ordinary income had amounted in the preceding year to nearly £110,000, with an extraordinary income, made up of legacies and donations, amounting to over £75,000. He hoped that the institution would never suffer for want of moral and financial support, and offered his warmest congratulations to those responsible for what he regarded as a great achievement. The Duke and Duchess of York then made a tour of inspection of the department under the guidance of Dr. Woodburn Morison and Sir James Hodsdon.

#### The Building.

The site for the new building is between the surgical and medical sections of the Royal Infirmary, and is entered off a covered corridor joining the two. Owing to the difference in level, there is a slight gradient on the various floors. The building is approximately 160 feet in length, with an average width of 60 feet; it consists of a sunk basement and two floors over with a flat roof designed to carry a third floor if extensions are found necessary at a later date. The basement contains the generating electrical plant and main control boards, with mechanics' workshop and general storage rooms. On the ground floor are situated several x-ray screening and treatment rooms, lecture and demonstrating hall, photographic and dark rooms, and the various private rooms for the staff, waiting and examination rooms. On the upper floor, accommodation is provided for electrical and massage treatment, with well lighted rooms for remedial exercises, radium treat-

ment, and artificial sunlight treatment. The structure of the building presents several novel features, designed especially with a view to furnishing the maximum of protection against the x rays. The construction is of steel framework with reinforced concrete floors and roof, and outer walls of stone with concrete dressings; the flat roof is covered with rock asphalt. For the protection of the operators and other members of the staff against constant exposure to the x rays, protective material has been incorporated in the walls of the x-ray rooms. Several experimental partition slabs were made and tested. Barium (barytes) was selected as giving the best results and being easily obtainable in sufficient quantity. The composition of the slabs finally selected as combining the greatest possible measure of strength and radiological protection was: 1 part rough sand, 2 parts engine ashes, 1 p Portland cement, 3 parts barytes. The slabs are of a thickness as to weigh 37½ lb. per superficial foot, each slab is adjusted by grooves to adjoining slabs. A further protection, the walls were plastered on each side with a 5/8 inch coat of barium plaster, and the same plaster has been used for the ceilings and floors. The amount of protection afforded by these walls is equivalent approximately to that given by sheets of lead 4 mm. thickness. The doors are of timber, covered with lead each side, and all hinges, handles, etc., are fully protected. Observation windows in the various cubicles have been provided with lead glass, equivalent in protection to 4 m of lead. Heating is provided by a vacuum steam system and ventilation is effected by extraction with high-speed electric fans. Fresh-air inlets are provided in all rooms the ground level.

#### Teaching Department.

Besides the various pieces of apparatus for screening in radiography and for deep penetration work, and apparatus for remedial exercises, ultra-violet light therapy and various forms of electrical application, special attention has been devoted to the teaching aspect of the institute. Radiology is to be taught as a definite special subject to the undergraduates, and a special diploma D.R.Edin., has been instituted. For this diploma a candidate will take a post-graduate course in physics at the university and carry out practical work in the infirmary, the course extending over a period of about a year. A large room is provided for lecture purposes suitably equipped with lantern viewing boxes, etc., and demonstrations can be given to small groups of students in smaller rooms. The staff of the department consists, in addition to Dr. Woodburn Morison (radiologist), of Dr. John O'Sullivan and Dr. W. Crichton Fothergill (assistant radiologists).

#### NEW CHILD WELFARE CENTRE IN GLASGOW.

A child welfare centre established by the Glasgow corporation was opened by Dr. Walter E. Elliot, M.P. Under Secretary of State for Scotland, on October 5th. The Lord Provost, Sir Matthew W. Montgomery, presided and said that one of the most important factors in improving the health of the people was to prevent disease. Although the death rate among infants had diminished considerably of late, he thought a great deal still required to be done. The Glasgow death rate of 102 per 1,000 compared very favourably with that of other large communities, but they hoped that the child welfare movement would produce a very large reduction even in this rate. Dr. Elliot, in declaring the centre open, said that while the infantile death rate was still falling, it was higher than it ought to be, and higher than the corresponding rate in England. Maternal mortality, however, was still high, and was not yet declining. In Scotland there were already 195 of these centres, and almost all large areas of population were now provided with them. The estimate for next year showed that about £218,000 was being spent on this work, of which about £120,000 was granted by the central authority. During last year about 20,000 children had attended these centres in Scotland, of whom about 14,000 were under 1 year of age. The aspect of the work which it was particularly desirable to develop was that of

children between the ages of 1 and 5 years. During this period cases of deafness, blindness, and other ailments often began and were later found to be permanent afflictions. Another aspect of the work which ought to be developed was maternal work, for at the various ante-natal clinics there had been only 8,000 cases in the past year, with some 21,000 attendances. Every encouragement and assistance should be available at this critical time. The speaker then dealt with the question of rickets, which, he said, was a reproach to Great Britain as a whole and peculiarly so to Scotland. They were only at the beginning of an investigation into this disease, but one or two very hopeful avenues of attack had recently been opened up. The question of feeding children was most important, and last year the Board of Health had devoted an important chapter in its report to the question of light treatment. They had decided that these two investigations must be followed up, and committees in Edinburgh, Glasgow, and Aberdeen would extend their investigations into these subjects as opportunity offered. He had hopes that this investigation in Scotland might make a definite contribution to medical science, which would be of advantage to the whole world.

#### HOSPITAL SERVICES IN SCOTLAND.

Representatives of hospitals and public authorities in Dumfries and Galloway attended a conference at Dumfries on October 7th, arranged by the Dumfries and Galloway Division of the British Medical Association, to discuss the question of a hospital policy for Scotland. The opening address was given by Dr. J. R. Drever, the Scottish Medical Secretary, who was a member of the Hospital Services Committee, which held several meetings last year to investigate this matter; frequent references have been made to the meetings of this committee in the *JOURNAL*, and at Dumfries Dr. Drever outlined its general findings and invited the conference to make a careful study of them with reference to the local conditions in Dumfries and Galloway. The committee had reported that on the whole the institutional accommodation in Scotland for infectious diseases, including pulmonary tuberculosis, was approximately adequate, but that it was deficient in respect of non-pulmonary tuberculosis, measles, whooping-cough, and pneumonia. Only three or four authorities had so far provided maternity hospitals, the total number of beds being about seventy, but a similar number of beds in maternity homes for normal confinements had also been obtained. In view of the admitted fact that a very large number of the private dwellings in industrial areas were quite unsuitable for the conduct of confinements, a considerable increase in the provision of institutional beds was required. Passing to the consideration of the medical services afforded by the Poor Law authorities, Dr. Drever stated that, apart from Aberdeen and Glasgow, there were no beds provided by Poor Law authorities which were immediately available for general hospital purposes; it was generally agreed that the parish council was not the proper body to make further hospital provision, but that the health functions at present controlled by the parish councils should be transferred to the larger local authorities. Whereas in Glasgow in 1841 the hospitals were made use of by 17 per 1,000 of the population, in 1924 the figure had increased to 45 per 1,000. At the present time many thousand patients were unable to get, at the proper time, the hospital treatment they required, and the committee had concluded that a minimum of 3,600 beds ought to be added as soon as possible to the hospital provision of Scotland. This total covered the requirements of maternity and child welfare work, and 600 of these beds might reasonably be provided by the local authorities. For the establishment of 3,000 beds £1,800,000 would be required, exclusive of equipment charges and sites. The whole of this money could not be obtained under the present voluntary system, although the Scottish hospitals at present were perfectly solvent and had £4,000,000 of accumulated funds. The recommendation of the committee, therefore, was that a sum of £900,000 should be provided by the Government for capital purposes, the remaining £900,000, together with the cost of the sites

and equipment, being provided from present voluntary sources. Wards for paying patients were also required, and Dr. Drever emphasized the value of increasing the close co-operation between local authorities and voluntary agencies.

#### POST-GRADUATE MEDICAL TEACHING IN GLASGOW.

The following arrangements have been made for post-graduate teaching in Glasgow from November to May, under the auspices of the Glasgow Post-Graduate Medical Association: Weekly demonstrations will be held on Wednesday afternoons, beginning on November 3rd, in medicine, surgery, obstetrics, and special subjects; the fee for this course is three guineas. Special courses have been arranged in ophthalmology, at the Glasgow Eye Infirmary, including a slit-lamp course for ophthalmic surgeons, during October and November, and a course qualifying for the diploma in ophthalmic medicine and surgery of the Royal Colleges of Physicians and Surgeons of England, from January till May, 1927. A special course at the Royal Hospital for Sick Children and the Royal Maternity and Women's Hospital will be held twice a week, on Tuesdays and Fridays, from November 23rd to December 17th inclusive. Instruction will be given on the preservation of the health of the mother and the newborn infant, and the subjects dealt with include the diagnosis and treatment of disease in the newborn, the relation of ante-natal complications and abnormal labour to the condition of the infant, and certain aspects of the pathology of the foetus and of the newborn child. Clinical assistantships are available during the winter months in most of the institutions taking part in the work of the association. Further information may be obtained from Dr. James Carslaw, secretary of the Glasgow Post-Graduate Medical Association, 6, Woodside Crescent, Glasgow.

## Ireland.

#### TYRONE COUNTY HOSPITAL.

Mr. EDWARD THOMPSON, F.R.C.S.I., in the course of his annual report on the Tyrone County Hospital, states that during the year 1925 considerable progress was made, as 101 more patients were admitted to the hospital than ever before without adding to the expense of maintenance. The patients admitted were scattered over the county in very fair average proportion. Considering the size of the unions, complaint has often been made that a hospital situated in Omagh is of no use to Cookstown or Dungannon; a hospital must be settled permanently somewhere, and what position, it is asked, could fulfil the necessary conditions better than a central position such as Omagh, with a railway junction connecting the whole county? It is important also to remember that the class of patient seeking relief at the County Hospital differs materially from those in district and other hospitals, because the great majority of them are serious surgical cases requiring operation, or acute medical cases, generally of a very difficult and troublesome nature. During the year 865 patients were admitted to the hospital; 437 were refused admission as incurable or not suitable. The average number of patients daily in hospital was 56, and their average stay in hospital 19.7 days. The expenditure amounted to £5,129, and of this sum £2,477 was earned by the Hospital Committee, leaving a balance of £2,652 granted by the county council, the cheapest and most useful expenditure of public money it is possible to imagine. If to this expenditure is added interest at 6 per cent. on £10,000 subscribed by the public to build the new hospital, it will be apparent that the income of the hospital about equals the county grant. The average cost of each bed occupied was £23 17s., and of each patient £5 6s. 9d. In anticipation of the coal strike, about forty tons of coal were laid in as a reserve, and if the cost of this, along with the payment of over £120 for repainting the hospital, is credited to this year's expenditure, it will be found that the total cost of the hospital for 1925 is considerably less than in the previous year, notwithstanding an increase of 9.5 per cent. in the number of patients

admitted. This is the last year in which a reduced expenditure can be expected, because owing to the demand of the Northern Local Government Board as regards audit, and similar demands on the part of the Nursing Council, a number of new officials will be necessary, and the extra cost, it is estimated, cannot be less than £1,000 a year. The average cost for the year per patient is the lowest of any county hospital in Northern Ireland. The number of major operations performed during the year was 425; this included 47 operations for the removal of appendices, with 42 successful results; 13 operations for the radical cure of hernia; 31 curettings of uterus; 25 laparotomies; and 4 operations for ruptured stomach.

#### GYNAECOLOGICAL AND OBSTETRICAL CONGRESS IN DUBLIN.

A fortnight ago we gave an account of the centenary celebrations of the Coombe Lying-in Hospital, Dublin, and mentioned the subjects and authors of papers read during the international gynaecological and obstetrical congress held in connexion with the celebrations. The proceedings of the congress are to be published as a special supplement to the *Irish Journal of Medical Science*, which, it is expected, will be ready for issue shortly. Copies (5s. 6d. post free) can be obtained on application to the Manager, at Parkgate Printing Works, Dublin. The September issue of the *Irish Journal of Medical Science* contained a special illustrated account of the congress. This will be sent also if the postal order is increased to 7s. 6d.

## Correspondence.

### DIAGNOSIS OF SMALL-POX.

SIR,—In view of recent happenings in the matter of small-pox, may I make a strong appeal to your readers to help to make known the elements of small-pox diagnosis to every one of our colleagues in the profession? In 1913 I wrote:

"It is essential to realize the mischief which may be done by unrecognized cases of small-pox. There is hardly any disease of which the prompt recognition is more important to the general community. Almost every outbreak in London in recent years has been started, or propagated and prolonged, by unrecognized cases." (*How to Diagnose Small-pox*, p. 1.)

Our profession has made a remarkable response to those indications. Missed cases are strikingly fewer than they used to be; but for that very reason they are now all the more conspicuous. Our principal duty, I submit, at a time like the present is to make sure that we have done all in our power to make the necessary knowledge known. Speaking for myself, although something has been done, there is much more that I should like to have been able to do. This is the point. Every qualified practitioner in the kingdom should have a knowledge of the simple groundwork of small-pox diagnosis in his hands and in his head. It is more imperative than a knowledge of the femoral artery.

We all know the anxiety and risk of being unprepared to meet a possible emergency—the risk of losing patient, reputation, and practice. That unpreparedness should never be allowed to continue if it can possibly be remedied. With this in view, I ask your permission again to mention two items especially. One a booklet termed *Small-pox Notes for Medical Practitioners, with Hints on Diagnosis*, price 8d.; the other a reprint of a post-graduate lecture, entitled *The Accurate Diagnosis of Small-pox*, price 6d. Both are obtainable from either the *Medical Officer*, 36, Whitefriars Street, E.C., or from George Wareham, 1, Budget Row, Cannon Street, E.C.4. To overcome the difficulty caused by an author having to mention his own works, and other difficulties in connexion with their distribution, their issue is being handed over to the Small-pox Clearance Voluntary Fund, of which for the time being I am honorary secretary. The main aim of this fund is the complete clearance of small-pox out of the country, that being a business-like and practical proposition.

Some 3,000 practitioners have been provided with one or the other of the above-mentioned booklets so far, principally owing to the fact that many public authorities, on the

recommendation of their responsible officers, have distributed copies to all the practitioners in their respective areas; an eminently reasonable proceeding, considering the value of the public service rendered by practitioners in this field of work. And in many cases this precaution has been wisely taken before the appearance of small-pox.

Reports show that such an issue is greatly appreciated. Practitioners are forewarned and forearmed: Their own confidence and standing are increased, the hands of the medical officers of health are strengthened, and, generally speaking, there is a heightening of the efficiency of the whole anti-small-pox line, which at the present time is the sole barrier standing between our people and the catastrophe of a small-pox epidemic.—I am, etc.,

London, W.6, Oct. 11th.

W. McC. WANKLYN.

### INTESTINAL DIVERTICULA.

SIR,—Dr. A. H. Rutherford, in your issue of September 11th (p. 502), suggests that some of the multiple diverticula of the colon described by us (*BRITISH MEDICAL JOURNAL*, 1926, vol. i, p. 130) are potential "food pouches or crypto-sacs" . . . "caused by the purse-string action of muscular fibres which, on their contraction, form a pouch or sac, into which semi-fluid faeces are drawn and where they become inspissated." We have delayed in replying in order to obtain and peruse the book to which he refers. We have now read the interesting account therein of observations made through a large artificial anus at the caecum. (*The Ileo-caecal Valve*, A. H. Rutherford, London, 1914).

On page 30 it is stated that a "pencil of firm faeces, 7.5 millimetres in diameter and 6 centimetres in length, was one day seen to be pressed out of an apparent round orifice in the wall of the caecum. This was pressed out with considerable force in a direction at right angles to the surface of the bowel, evidently moulded by the circular aperture through which it emerged. After the faecal mass had been extruded, no orifice, however, could be discovered, and the spot where it had come from had the same appearance as the rest of the intestine. The nurse in charge told me she frequently observed this appearance in different positions of the colon, and it had no relation to the site of the ileo-caecal orifice, but was noticeable in an area nearer the rectum."

Such a pencil of faeces might be discharged from one of the large multiple diverticula of the colon such as our paper dealt with. We have published a picture in which such pencils can be seen (*Quart. Journ. Med.*, 1925, xix, Fig. 26, Plate 4).

Dr. Rutherford states that potential food pouches "occur in numbers along the inner wall of the large intestine"; and suggests that these, if diseased, may give rise to established diverticula. In the radiological examination of about 3,000 large bowels during life we have not observed such pouches other than (1) the normal haustra, (2) the rare cases of traction or other single diverticula, or (3) the appearances we have described as diverticulosis.

If pockets such as the crypto-sacs of Dr. Rutherford became diseased to form diverticula, the latter would from the beginning be of large size; whereas early diverticula are minute and can be seen to enlarge as time goes on. Tiny pockets are nearly always found near fully developed ones.

We should expect also that most, or all, of the large diverticula, if formed from "crypto-sacs," would retain some muscular power, but this is not so. It was observed in serial pictures of our case, illustrated in Fig. 10, and referred to by Dr. Rutherford, that the small diverticula showed slight contraction of their bodies and necks, whilst the bigger pouches appeared inert, even during active contractions of the haustra from which they arose. It is true that in some cases comparatively large diverticula have been observed to empty, and sometimes to empty in groups; but we do not regard such an observation as showing that the pouches were part of the normal structure of the bowel.

As regards the wall of the bowel, which was "full of holes," as observed by the nurse, but usually appeared normal to the doctor, the orifices of diverticula which are not discharging are in life—for example, with the sigmoidoscope—or after death difficult to see. There is nothing in the account to exclude the possibility that the bowel of Dr. Rutherford's case was the seat of all stages of the disease.—We are, etc.,

E. I. SPRIGGS.

O. A. MARXER.

Ruthin Castle, North Wales, Oct. 8th

## MIDWIFERY IN GENERAL PRACTICE.

SIR,—I understand there is shortly to be in force a Regulation which lays down that every practitioner attending a midwifery case must notify such case to the medical officer of health if the temperature should be 100.4° for twenty-four hours; that he is to state what vaginal examinations he has made, also vaginal examinations made by others under him, and the names and addresses of such persons; and that he is to supply a kind of résumé of the health of the patient before and after confinement.

I am in a country practice, and my confinements amount to eighty or ninety a year, for which I receive £1 10s. each (when paid). There is no district nurse in the village and no qualified midwife. The people are poor working-class, and would be deeply insulted were I to demand a fee for ante-natal examination. After this Regulation comes into force my only course, as far as I can see, will be to drop midwifery work unless I can obtain the assistance of a qualified midwife.

Midwifery practice is slowly but surely slipping into the hands of certificated midwives. The majority of the doctors in this district, as in many others, have given up attending confinements among their poorer patients. This is partly, no doubt, because of the small fees, but largely, I believe, on account of the red tape now prevalent, and because the blame for whatever goes wrong is laid at the practitioner's door.

I may be old-fashioned, but I believe that midwifery should be in medical hands. In the first place, a midwife is to a very large extent precluded from using any means for alleviating pain; and secondly, in a great many abnormal cases the patient is kept much too long before the midwife calls in a doctor. In spite of the laudation of midwives which I have read, a curious fact remains unexplained. Why do better-class women invariably demand the services of a doctor in addition to those of the qualified nurse? Why are they not content to be attended by a midwife alone, like their poorer sisters? It is not wholly a matter of fees. To compare the services of a midwife, who only takes responsibility for normal or semi-normal cases, with those of the doctor, who is expected to undertake all cases, is absurd, for it is among the difficult cases that 90 per cent. of the trouble occurs.

It seems to me a very serious matter that working-class women should be deprived of the services of doctors, largely because we are so bound down by rules and regulations that midwifery practice has become a daily menace to our peace of mind, and medical men are refusing to have anything to do with it. It is time the general practitioner asserted himself to put an end to the unjust persecution he labours under; and the remedy does not consist in throwing overboard his responsibilities.—I am, etc.,

September 22nd.

INQUIRER.

## A WARM ENVIRONMENT FOR RHEUMATIC PATIENTS.

SIR,—Dr. Fortescue Fox has, under the above heading, drawn attention in the JOURNAL of October 9th (p. 664) to the importance of giving "spa treatment" to rheumatic patients only under suitable conditions, and also to the detrimental effect of chill after treatment.

Having myself suffered acutely, from time to time, from various conditions generally included under the term "rheumatic," and having had "spa treatment" in various forms at several spas, health resorts, and hydro-therapeutic institutions, and also having prescribed and watched the effects of "spa treatment" in a large number of rheumatic patients, I can fully endorse Dr. Fortescue Fox's contentions.

The rheumatic patient is peculiarly sensitive to sudden temperature changes, and is generally responsive to treatment by heat, whether by thermal baths, radiant energy, diathermy, or by other methods, provided that they are carefully prescribed and efficiently administered under suitable conditions. Rest after a thermal treatment is essential. It should be adequate in duration and be taken in a room heated to a suitable temperature. Cold resting rooms are detrimental as cooling is too rapid, whereas overheated rooms are injurious in preventing efficient

cooling. These and other points require careful consideration as "spa treatment" will probably be more popular in the future than it has been in the past, and also because it is possible that at no distant date it will be available for the large number of rheumatic cases which are entitled to medical benefit under the National Health Insurance scheme.—I am, etc.,

Torquay, Oct. 11th.

K. R. COLLIS HALLOWES, M.B.

## SANATORIUM TREATMENT.

SIR,—May I be permitted to make a few observations in reply to the letters which have appeared in the JOURNAL during the past few weeks in criticism of the recent paper on this subject in the *Annals of Eugenics*?

Dr. Walters (September 11th) says that "to arrive at reliable conclusions in such an inquiry it is essential to choose similar material in the two groups." It can never be possible in sociological investigations to secure exactly similar material, and hence much of the labour involved in the investigation was devoted to ensuring that such differences as existed between the groups compared owing to selection for sanatorium treatment should be adequately corrected for, and to this end the ten factors of age and sex, stage of disease and severity of symptoms, nutrition, financial resources, grade and cleanliness of house, degree of overcrowding, and home ties, were all examined in detail, and, where necessary, allowed for. Dr. Walters considers that these, though relevant, do not cover the whole ground, but he does not suggest what factors have been omitted, and I think it is a reasonable assumption that the indefinable factors could have, in comparison with those named, very little influence on the relative progress of the groups. His objection that the two groups were not mutually exclusive, because the sanatorium-treated received in addition other forms of treatment before or after their stay there, fails on the grounds of general logic. Thus, in comparing groups of patients under treatment of various kinds for a period of  $x$  years we found that those who had dispensary or home treatment for the whole  $x$  years fared slightly better if anything than those who had sanatorium treatment for  $s$  years plus dispensary or home treatment for the remaining  $(x-s)$  years; both these groups had in common non-sanatorium treatment for  $(x-s)$  years, hence it follows that the differences in progress arose from the remaining  $s$  years, and those who spent this period in sanatorium fared no better than those who spent it in the other forms of treatment. To put it in another way, if 1,000 patients treated with 10-grain powders consisting of drugs A and B in varying proportions fare no better than 1,000 patients treated with 10-grain powders of A alone, it must logically follow that B alone is no more effective than A alone. An obvious retort is that the dose of B was never large enough to accomplish anything; but I would point out that the average period spent at sanatorium in our material was six months, an average considerably higher than that for patients treated, for example, by the Lancashire County Council. Had we not better frankly admit that there are small hopes indeed that any large group of patients are ever likely to be persuaded to spend more than an average of six months in a municipal sanatorium, however excellent it may be?

Dr. Gillespie (September 18th) objects that a considerable proportion of the patients were lost sight of before six years had elapsed; that the limiting period for classing a patient as "sanatorium-treated" was taken as low as fourteen days; and that the presence or absence of tubercle bacilli in the sputum was not made the indispensable criterion for diagnosis. The correlation method, by which the time under observation was made constant by partial correlation, overcame the first of these objections entirely, and the results confirmed those arrived at by the other methods. The objection to a fortnight as limiting period has been already answered on logical grounds, and, moreover, since there was found to be no correlation between time spent at sanatorium and progress, the choice of this arbitrary point of division makes no difference to the conclusions. If it were possible to confirm every diagnosis by the finding of tubercle bacilli in the sputum, it would, of course, greatly simplify the problem both for the

tuberculosis officer and the medical statistician; but as the bacilli have often an unfortunate habit of not coming to light till the disease is well advanced, the absence of such confirmation in many early cases is a fact which has to be faced in any study of this kind. In cases where such a short cut to diagnosis fails, we may surely concede to the tuberculosis officers an ability to diagnose the disease from the other signs and symptoms with sufficient accuracy to render such diagnosis fit for statistical treatment. The failure to find bacilli neither precludes a patient from notification nor from sanatorium benefit, and it is therefore idle to speak of the finding of bacilli as a *sine qua non* in diagnosis. I note, for example, that only 29 per cent. of 1,521 female patients in the L1 stage who were sent to sanatoriums of the Lancashire County Council from 1914 to 1923 had the diagnosis confirmed in this way. If diagnosis apart from tubercle bacilli is liable to be faulty there is no reason to suppose that in our data such mistakes affected unequally the groups of patients compared, since they were all examined by the same medical officers, and all cases in which their diagnosis remained doubtful were rigorously excluded.

If, as Dr. Weatherhead (September 25th) seems to suggest, diagnosis without bacilli is valueless, then the inferences which must follow are not pleasant to contemplate. That all do not share this opinion, however, is shown by the letter of Dr. Prest (September 25th), who writes: "The diagnosis of tuberculosis should be made by a study of the history of the patient and a careful inquiry into symptoms, and not by the presence of physical signs and the finding of tubercle bacilli in the sputum." In order to show, however, that the sanatorium group did not contain an undue proportion of cases with positive sputum, we have taken out the following figures:

Percentage of patients in whom sputum was found positive:

|                          |     |     |      |
|--------------------------|-----|-----|------|
| Sanatorium-treated group | ... | ... | 9.4  |
| Non-sanatorium group     | ... | ... | 10.2 |

In this sanatorium sputum-positive group 31.0 per cent. were of class I3, as compared with 26.6 per cent. in the other group. Hence there is no evidence of the more "definite" cases being chosen for sanatorium.

Dealing only with sputum-positive cases, we have as comparative percentages dead or not improved:

|  | Males.   | Females.  |
|--|----------|-----------|
| Non-sanatorium cases ...               | 83.9±3.3 | 92.1±1.8  |
| Sanatorium-treated, less than 3 months | 96.4±2.4 | 100.0±3.8 |
| Sanatorium-treated, more than 3 months | 91.9±3.0 | 88.9±5.0  |

These figures show no significant differences for females, but a significant advantage to the non-sanatorium group for males. For the sputum-negative cases the corresponding percentages dead or not improved were:

|  | Males.   | Females. |
|--|----------|----------|
| Non-sanatorium cases ...               | 56.0±3.5 | 48.6±2.1 |
| Sanatorium-treated, less than 3 months | 58.6±6.2 | 47.4±7.7 |
| Sanatorium-treated, more than 3 months | 51.9±6.5 | 54.3±5.7 |

These show no significant differences for either sex. These figures are sufficient to indicate that subdivision on the ground of sputum findings would not have altered the conclusions reached in the paper.

The authors had no prior reason to doubt the efficacy of sanatorium treatment; they were only interested to get at the truth, whether unpalatable or not. Such a course can only benefit our profession and our patients alike in the long run. If an investigation of a similar nature can be undertaken on sound lines on the data of a tuberculosis unit with modern sanatorium in England, and if this yields results more satisfactory to us all, the authors will be only too pleased to know that their disappointing conclusions are not applicable to sanatoriums in general.—I am, etc.,

Galton Laboratory, University College,  
London, W.C.1, Oct. 1st.

PERCY STOCKS.

SIR,—Having now perused the memoir by Messrs. Stocks and Karn on "The influence of sanatorium and dispensary treatment and housing conditions on pulmonary tuberculosis." I may, perhaps, be allowed a word or two of criticism.

The fact that the presence or absence of the tubercle bacillus has not been taken into consideration by the authors in the grouping of the cases robs this investigation

of a great deal of its value. Indeed, it introduces a very serious fallacy.

Again, as your correspondent, Dr. Walters, has pointed out, sanatorium treatment—to be of any permanent value—must be of long duration, certainly of at least twelve months; and to regard as "sanatorium treated" patients who have been in an institution for fifteen days only seems to be rather absurd. These cases should have been classified as "otherwise treated."

But one must admit that sanatorium treatment, especially if it is of short duration, has little or no effect on the ultimate prognosis of cases discharged as improved or quiescent only. The mental factor comes into play, and the patient loses heart, and on the first setback he gets he goes down hill rapidly. That is the reason why we prefer to cure one case rather than "patch up" twenty, and when institutions are anxious to get "suitable cases" they have this in mind, and not mere statistical considerations, as the authors suggest.—I am, etc.,

Grampian Sanatorium, Kingussie, Oct. 4th.

FELIX SAVY.

#### APPENDICITIS AND VEGETARIANISM.

SIR,—During recent years I have seen many Oriental and relatively few European patients: I have removed many European appendixes but never an Oriental one.

In Kurdistan I once operated on a native for what I thought was appendicitis, but found early tuberculosis of the caecum. Twice in natives of Burma I have found suggestive symptoms, but these cleared up in a day or two, did not recur, and did not justify operation. One man complained of a "nat" (devil) in the right iliac region, but the "devil" was located in the urethra and right seminal vesicle.

In Mesopotamia and Burma the natives eat meat, but it is well diluted with rice, split peas, coarse wholemeal unleavened bread, and such green vegetables as are obtainable; they do not eat potatoes. On making a sanitary inspection of Burmese or Indian lines one cannot help noticing that most of the faeces in the latrine tins are semi-solid. Most Orientals pass their motions regularly the early morning and squat while doing so.

Professor Wilkie has shown that gangrene rapidly occurs in an isolated segment of the small intestine of a cat on meat, but not in that of a cat fed on carbohydrate. Dr. Leonard Williams points out that owing to a large vegetarian uncooked diet, regular habits, and a squatt defaecation posture, the savage completely empties his lower bowel every day, and thereby escapes the large group of diseases due to intestinal stasis. It seems logical to suppose that if we were to adopt their habits we should not suffer from appendicitis.

I fear, however, that so long as eating and drinking hold their places among the chief pleasures of Western civilization we shall continue to suffer from alimentary sepsis.—I am, etc.,

H. WILLIAMSON, M.D., F.R.C.S.Ed.  
Captain I.M.S.,  
Surgical Specialist, Burma District.

Ightham, Kent, Oct. 5th.

#### POOR LAW MIDWIFERY FEES.

SIR,—I have read some correspondence in the JOURNAL on the fees paid by life insurance companies for examination and report, and agree that the minimum fee should be one guinea, but irrespective of the amount of the policy I have insisted on this for many years.

What appears to me much more unsatisfactory is the case of the Poor Law medical officer, who receives from the board of guardians the wretched fee of half a guinea for a midwifery case, whether he has to deal with a neglected shoulder or a placenta praevia with locked twins. This was the fee when I held such an appointment thirty-four years ago, and it is still the same. If I resign the job and my partner refuses it (as he would), it would doubtless result in the introduction of an opposing practitioner into a village which will only support two men, so I am rather "up a tree." It is quite time that this state of affairs was altered. It is nothing less than a scandal that an experienced man should be offered, and obliged to accept, such a paltry fee.—I am, etc.,

Topham, Devon, Oct. 7th

R. C. WONSLEY.

## Obituary.

### JAMES BARRY BALL, M.D., F.R.C.P.,

Consulting Physician, Throat, Nose and Ear Department,  
West London Hospital.

Dr. JAMES BARRY BALL, who died at his residence at Abingdon, Berks, on October 2nd, aged 77, was born in Ireland in 1849, and received his medical education at University College, London. He obtained the diplomas of M.R.C.S.Eng. in 1870, and M.R.C.P.Lond. in 1885, and was elected F.R.C.P. in 1907. He graduated M.B.Lond. in 1871, proceeding M.D. in the following year.

He first entered general practice in Brixton, but in 1885 was appointed assistant physician to the West London Hospital. Two years later he was given charge of the throat and nose department, and of the ear department when that was added later. In 1905 he was appointed consulting physician and a member of the board of management. His other appointments included those of consulting physician to the Hospital of St. John and Elizabeth, lecturer in diseases of the nose, throat, and ear to the West London Post-Graduate College, and examiner in laryngology and otology to the Royal Army Medical College. He was the author of a *Handbook of Diseases of the Nose and Pharynx*, and contributed articles to *Quain's Dictionary of Medicine* and to the *Transactions of the West London Medico-Chirurgical Society*. Dr. Ball was at one time a member of the British Medical Association, and in 1907 was a Vice-President of the Section of Laryngology, Otology, and Rhinology at the Annual Meeting of the Association at Exeter. He was much liked during his long period of practice in London, both by his brother specialists and by other members of the profession with whom he came in contact. Though his manner was always conciliatory, he held the opinions at which he arrived with tenacity and did not hesitate to express them when called upon. He leaves a widow and one daughter.

Dr. CHARLES GEORGE MACLAGAN, who died recently, was born in 1860, and was educated at Berwick Grammar School and Edinburgh University, where he graduated M.B., C.M. in 1883. Until his father's death he was associated with him in his practice in Berwick-on-Tweed, and later continued it by himself. He held the appointment of medical officer of health for Berwick, and was also an Admiralty surgeon. He had been surgeon captain in the Volunteers; during the late war he was chairman of the military tribunal; he was also chairman of the Berwick Infirmary during the whole war period. In addition to his medical work he took an active part in public life, being elected to the Berwick Town Council in 1897 and raised to the bench of aldermen in 1909. He held the post of sheriff in 1903, and was mayor in 1908, 1921, and 1922. He was appointed a justice of the peace in 1914, was chairman of the Berwick Education Board, and later a member of the Education Committee of Northumberland, serving also on the county Panel Committee. For many years he was an active supporter of the British Medical Association. He held the post of president of the North of England Branch in 1888 and in 1923; he was chairman of the North Northumberland Division in 1916, and representative on the Branch Council from 1905 to 1919.

Dr. LOUIS ESTEVAN GREEN DE WOOLFSON, who died on September 11th, received his medical education at St. Thomas's Hospital and in Paris, and obtained the L.S.A. in 1881, and L.R.F.P.S.Glas. and L.M. in 1883. After conducting a large practice in Shrewsbury he moved to Swansea, and later to London. At one time or another he held the appointments of assistant surgeon to the Shropshire Eye, Ear, and Throat Hospital, medical officer of health for Wednesfield, surgeon in charge of the ear, nose, and throat department in the Queen's Hospital for Children, and surgeon to the ear, nose, and throat clinic, Hockley. He was an examiner for the St. John Ambulance Association, and ambulance surgeon to the G.W. and L.N.W.

Railway services. Dr. de Woolfson was a member of the Royal Institute of Wales and the Royal Sanitary Institution of Great Britain. During the war he was medical officer in charge of a recruiting area in the Southern Command. He was also a casualty surgeon to St. Paul's Skin Hospital, London, and acted as consultant for candidates for the priesthood for the Roman Catholic Church in Spain. He was an accomplished linguist, and spoke fluently English, French, German, Italian, and Spanish.

Dr. JOSEPH PATRICK FRENGLEY, who died at Wellington, New Zealand, on August 1st, was born in Ireland in 1873, and received his medical education at the Catholic University, Dublin, where he graduated M.B., B.Ch., B.A.O., in 1895, proceeding M.D. in 1899. He obtained the diploma F.R.C.S.I. in 1899, and two years later the D.P.H. of both London and Dublin. In 1902 he was appointed district health officer at Nelson, and was thus one of the pioneers of the public health service in New Zealand. After holding similar posts at Auckland and Wellington, as well as being senior health officer for the combined districts of Wellington, Hawkes Bay, Marlborough, and Nelson, he became deputy chief health officer in 1913, and four years later received the additional appointment of deputy inspector-general of hospitals. After the passing of the Health Act in 1920, Dr. Frengley held the post of deputy director-general of health in New Zealand, but in consequence of prolonged ill health he subsequently undertook the less arduous duties of director of the division of food and drugs in the health department. He took an active interest in the scientific side of medicine, and was an examiner for Otago University. He was one of the first advocates of a municipal milk supply for the city of Wellington. He leaves a family of one daughter and three sons, two of whom are members of the medical profession in New Zealand.

The following well known foreign medical men have recently died: Dr. GEORGES THIBIERGE, the Paris dermatologist; Dr. O. W. MADELUNG, formerly professor of surgery at Strasbourg, aged 80; Dr. ADOLF LESSER, emeritus professor of medical jurisprudence at Breslau, aged 75; Dr. F. B. HORMANN, professor of physiology at Berlin University, aged 55; Dr. OSCAR BLOCH, emeritus professor of surgery at the University of Copenhagen, aged 79; Dr. EDWARD BRONXON, a New York dermatologist and author of an essay on the sensation of itching, published in the New Sydenham Society's publications, aged 83; and Dr. ALESSANDRO CAMUSSO, professor of obstetrics and gynaecology at Cordoba.

## The Services.

### DEATHS IN THE SERVICES.

MAJOR WILLIAM EDWARD MARSHALL, M.C., R.A.M.C., died on September 24th, of gastritis, at Khartoum, aged 45, within ten days of taking up the post of principal medical officer of the Sudan Defence Force. He was the second son of the late David Marshall, county clerk of Perthshire, and was educated at University College, Dundee, St. George's Hospital, and Edinburgh University, where he graduated M.B. and Ch.B. in 1902; he took the D.P.H. at St. Andrews in 1906. After filling the posts of house-surgeon of Perth Royal Infirmary, resident medical officer of Dundee District Asylum, and assistant bacteriologist at the Lister Institute of Preventive Medicine, he entered the R.A.M.C. as a lieutenant on August 1st, 1908, received a brevet majority on June 3rd, 1918, and became major on August 1st, 1920. He had previously served in the Egyptian Army from October, 1909, to December, 1913, and from 1919 to 1922, and before his return to the Sudan was deputy assistant director of pathology at the Royal Victoria Hospital, Netley. He served throughout the recent great war, was twice mentioned in dispatches, in the *London Gazette* of November 14th, 1916, and September 17th, 1917, and received the Military Cross in November, 1916.

Major Ernest Cyril Phelan, D.S.O., M.C., R.A.M.C., died on August 17th, aged 45, while serving with the British force of occupation on the Rhine. He was born on February 16th, 1881, and was educated at Trinity College, Dublin, where he graduated as M.B., B.Ch., and B.A.O., in 1906. Entering the R.A.M.C. as lieutenant on July 30th, 1906, he became major after twelve years' service. He served in the recent great war, when he was twice mentioned in dispatches, in the *London Gazette* of February

17th, 1915, and December 24th, 1917, and received two decorations—the Military Cross on February 18th, 1915 (when he was one of the earliest recipients of that order, founded on January 1st, 1915), and the D.S.O. on January 1st, 1918.

Major Harold Stewart Dickson, R.A.M.C., died of pneumonia in the nursing home at Srinagar, Kashmir, on August 31st, aged 46. He was born on April 16th, 1880, and was educated at Bart's, taking the M.R.C.S. and L.R.C.P. Lond. in 1905. He entered the R.A.M.C. in July, 1909, received a brevet majority in June, 1919, and became major less than two months afterwards—on July 27th, 1919. He was placed on temporary half-pay, on account of ill health, on January 7th, 1921, but rejoined within a year. He served in the war of 1914-18, gaining his brevet as major.

## Medico-Legal.

### A DANGEROUS DRUGS PROSECUTION.

At Marlborough Street Police Court, London, on October 8th, Mr. Cancellor, the stipendiary magistrate, heard summonses preferred by the Director of Public Prosecutions against John Kynaston, whose address was given as Langham House, Regent Street, W., for aiding, abetting, counselling, and procuring Rowland Pawsey to attempt to obtain possession of a dangerous drug—powdered opium—contrary to the provisions of the Dangerous Drugs Act, 1920, and, further, under the Medical Act, 1858, with falsely describing himself as a recognized licentiate in medicine and surgery by the use of the description "M.R.C.S., L.R.C.P. Lond."

Mr. Vincent Evans, for the Director of Public Prosecutions, said the defendant treated a Mr. Pawsey for catarrh, and, in furtherance of the treatment, handed him a prescription. At the top of the prescription were the words "Late R.A.M.C., L.R.C.P., M.R.C.S.," and at the bottom the defendant had signed his name, adding, "Lieutenant-Colonel R.A.M.C., retired, M.R.C.S., L.R.C.P. Lond." As a matter of fact in 1922 his name was removed from the *Medical Register* by the General Medical Council, and his name was subsequently removed from the registers of the two Colleges in question.

The defendant objected to being referred to as "Mr. Kynaston," saying he was a retired lieutenant-colonel of the R.A.M.C.

Rowland Pawsey, registrar of marriages, Marylebone, cross-examined by the defendant, said he did not ask the defendant to give him a dangerous drug. The witness was aware that the defendant had had a dispute with the General Medical Council, and gathered further that the defendant was no longer on the *Medical Register*; witness inferred that he had been removed. The defendant had not entered into a conspiracy to "aid, abet, counsel, or procure" the witness to get the drug.

C. Siggers, a chemist of Abbeville Road, said that Mr. Pawsey handed him the prescription. Cross-examined by the defendant, witness said he had no reason to suppose that Mr. Pawsey required the drug for an improper purpose, but, after making inquiries, witness refused to make up the prescription because the defendant's name was not on the *Medical Register*.

The defendant urged that there was no case whatever to go before a jury. On the first summons he elected to go for trial. The hearing was adjourned for further argument.

## Universities and Colleges.

### UNIVERSITY OF CAMBRIDGE.

THE third examination for medical and surgical degrees will be held from Tuesday, December 14th, to Thursday, December 17th. Part I (Surgery, Midwifery, and General Practice) will be held on December 14th, and Part II (Principles of Medicine, Pathology, and Physiology) on December 15th. The examination will be held at the University of Cambridge. Names of candidates should be sent to the Registrar on or before October 26th.

### UNIVERSITY OF SHEFFIELD.

Dr. J. H. BLAKELOCK, M.Sc., M.B., Ch.B. Sheff., has been appointed to the post of assistant bacteriologist.

### ROYAL COLLEGE OF SURGEONS OF ENGLAND.

THE annual meeting of Fellows and Members will take place at the College, Lincoln's Inn Fields, on Thursday, November 12th, at 3 p.m.

Copies of the report to be presented can be obtained by any Fellow and Member on application to the Secretary, from whom copies of the agenda (to be issued on or after November 12th) can also be obtained.

### ROYAL FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW.

THE following, after examination, have been admitted as Fellows of the Royal Faculty of Physicians and Surgeons of Glasgow:

A. Barr, A. A. Bell, J. A. Bingham, D. N. Black, A. D. Blakely, J. M. Christie, T. H. J. Douglas, A. Garrov, E. H. Jaffi, W. D. MacFarlane, F. G. Mackie, T. K. MacLachlan, W. McWilliam, G. T. Mowat, W. A. Sewell, H. L. Whittingham, J. M. Young, H. F. Young.

## Medical News.

THE minutes of the evidence taken before the Royal Commission on Lunacy and Mental Disorder have been published in three volumes. The first volume includes the evidence taken between October 7th, 1924, and February 10th, 1925, and the second that between February 24th and December 11th, 1925; these two parts are published at one guinea each net. The third volume contains the index and appendices and is published at 10s. 6d. net. The three volumes may be obtained from H.M. Stationery Office, Adastral House, Kingsway, W.C.2; York Street, Manchester; 1, St. Andrew's Crescent, Cardiff; 120, George Street, Edinburgh; or through any bookseller.

AT the quarterly meeting of the Grand Council of the British Empire Cancer Campaign, on October 12th, the chairman of the Finance Committee, Sir Richard Garton, urged the necessity for a sustained effort to obtain adequate funds to meet the increasing calls for assistance in researches into the cause of cancer. Mr. J. P. Lockhart-Mummery, chairman of the Executive Committee, announced that the visits of the members of the Intelligence Committee to the principal American and Continental cancer research laboratories would shortly terminate, and that reports on the most recent work on cancer outside the British Empire would be submitted to the Grand Council. Lieut.-General Sir John Goodwin reported that additional county committees were being formed in all, Durham, Hampshire, Sussex, and Surrey. Sir Jones were elected members of the Grand Council, and Professor Leiper was appointed a member of the Scientific Advisory Committee of the Campaign in place of the late Sir William Leishman.

TICKET holders for the annual service of the Guild of St. Luke, at Westminster Abbey, on October 17th, are requested to be at the West Cloister door not later than 6.15 p.m.

THE fiftieth anniversary dinner of the Cambridge Graduates' Club of St. Bartholomew's Hospital will be held at King Edward VII Rooms, Hotel Victoria, Northumberland Avenue, on Wednesday, November 10th, with Sir Humphry Rolleston, Bt., K.C.B., in the chair. The honorary secretaries are Dr. H. N. Burroughes and Mr. R. M. Vick.

THE annual dinner of past and present students of University College Hospital will be held at the Hotel Cecil, Strand, W.C., on Wednesday, October 27th. Dr. Philip D. Turner will take the chair at 7.30 p.m. Tickets, price 12s. 6d. (not including wine), may be obtained from the honorary secretaries, Mr. Gwynne Williams, F.R.C.S., and Dr. F. M. R. Walshe, University College Hospital Medical School.

THE old students' dinner of St. Thomas's Hospital will be held at the Hotel Victoria, Northumberland Avenue, London, on Friday, October 29th. Dr. R. Percy Smith will take the chair at 7.30 p.m.

SIR ARTHUR STANLEY will deliver the presidential address at the meeting of the Incorporated Association of Hospital Officers to be held at 28, Bedford Square, W.C.1, on Wednesday, October 27th, at 7 p.m.

A NEW series of post-graduate clinics arranged by the University of Sheffield commences to-day (Friday), October 15th, at 3.30 p.m., when Mr. Brockman lectures on conditions simulating the acute abdomen. The meetings, which take place at the Royal Infirmary, Sheffield, will be continued on succeeding Fridays up to and including Friday, December 17th, at the same hour.

AT the meeting of the Post-Graduate Hostel at the Imperial Hotel, Russell Square, W.C.1, on Tuesday, October 19th, at 9 p.m., Mr. Frank Kidd will open a discussion on pyelonephritis. On Wednesday, October 20th, at 9 p.m., Mr. J. P. Lockhart-Mummery will discuss the prognosis of rectal cancer. All medical practitioners are cordially invited.

THE second of the series of lectures on emergencies in medicine and surgery organized by the Fellowship of Medicine will be delivered by Mr. Joseph Adams on acute appendicitis on October 21st, at 5 p.m., in the lecture hall of the Medical Society, 11, Chandos Street, W., and on the same day a special lecture demonstration on cataract will be given by Mr. A. Caddy at the Royal Westminster Ophthalmic Hospital at 5 p.m. Both lecture and demonstration are open to members of the medical profession without fee. From November 1st to 13th there will be a course for general practitioners at the Hampstead General Hospital in medicine, surgery, and the specialties; and from November 1st throughout the month a course in venereal diseases at the London Lock Hospital. From November 15th to December 4th a course in gynaecology will be held at the Royal Waterloo Hospital; from November 15th to December 11th a course in dermatology, including pathology if desired, at St. John's Hospital; from November 22nd to December 18th a late afternoon course in

neurology at the West End Hospital for Nervous Diseases; from November 29th to December 11th a course in diseases of the chest at the Victoria Park Hospital; from November 22nd to 27th a course in proctology at St. Mark's Hospital; and from November 22nd a course for practitioners at the London Temperance Hospital. Copies of all syllabuses, the General Course Programme of the Fellowship, and its Journal, may be obtained from the Secretary of the Fellowship, 1, Wimpole Street, W.1.

PROFESSOR DR. C. RASCH of Copenhagen will give an address on the effect of light on the skin and skin diseases, at the meeting of the Dermatological Section of the Royal Society of Medicine, 1, Wimpole Street, at 5 p.m., on Thursday, October 21st.

THE annual meeting of the National Association of Insurance Committees will be held at the Hearts of Oak Buildings, Euston Road, N.W.1, on October 21st and 22nd and if necessary October 23rd.

A MATINÉE in aid of the funds of the Tavistock Clinic, the objects of which were described in the Educational Number of September 4th, 1926 (p. 453), will be given, by permission of the Co-optimists, at His Majesty's Theatre on Friday next (October 22nd), at 2.30 p.m. Particulars can be obtained from the Honorary Secretary of the Tavistock Clinic, 51, Tavistock Square, W.C.1.

THE Royal Sanitary Institute will hold its thirty-eighth congress at Hastings next July. The Home Secretary, Sir William Joynson-Hicks, Bt., M.P., will be president. In connexion with it there will be a health exhibition.

UNDER the housing schemes undertaken by the London County Council since the war the number of houses and tenements completed up to the end of September is 14,542 (more than half of them at Becontree), and 4,344 houses and tenements are at present under construction.

AT the September matriculation of the University of London there were 40 successful candidates in the first division and 380 in the second division; 40 took the supplementary certificate in Latin, 5 in mathematics, and one each in Greek, chemistry, mechanics, French, and music.

A PORTABLE x-ray equipment has been designed in the research department, Woolwich, for the examination of aeroplanes. The details and drawings are published in "R.D. Report No. 68" by H.M. Stationery Office, with illustrations and working drawings, and may be of interest to medical radiologists.

DR. A. J. MARTIN, on his departure from Bloxwich, where he practised for thirty-two years, has been presented by his friends and patients with a bookcase, a clock, and a gold cigarette case.

A TABLET to the memory of the late Dr. Claude B. Ker placed in the entrance hall of the Edinburgh City Hospital, Colinton, was unveiled recently by Lady Sleight. The memorial, which is of marble and bronze, bears in relief a portrait of Dr. Ker and an inscription recording that he was superintendent of the hospital from 1897 to 1925.

OWING to the further generosity of Mr. George Buckston Browne, the sum of £1,000 has been added to the Memorial Prize Fund of the Harveian Society of London which bears his name. The council of the society will therefore be able to give more valuable prizes for successful essays.

THE fifth Rumanian Congress of Oto-rhino-laryngology will be held at Bucarest, under the presidency of Dr. A. Costiniu, on October 24th and 25th, when the following subjects will be discussed: adenoids in their endocrine aspects, introduced by Koleszar, Vasiliu, and Tatar-Iy; deaf-mutism in Rumania, introduced by Darabau. Farther information can be obtained from the general secretary, Dr. Mayersohn, 81, Calea Musilov, Bucarest.

COURSES of lectures in German are arranged by the University of Vienna throughout the year in connexion with post-graduate medical instruction. Special international courses are to be held in February, June, September, and November, each lasting a fortnight, and dealing with the recent work in various specialties. Syllabuses of both these courses may be obtained, free of charge, from the Kirs Bureau of the Vienna Faculty of Medicine, Schlüsselgasse 22, Vienna VIII.

DR. CLAUD SCHILLING, professor at the Robert Koch Institute for Infectious Diseases, Berlin, has been appointed a member of the Malaria Commission of the League of Nations.

THE present epidemic of typhoid fever in Hanover is attributed to infection of one of the three waterworks supplying the town. Up to September 17th 1,504 patients, of whom 42 have died, have been admitted to hospitals, but the number of cases nursed at home is not yet known. A severe epidemic of typhoid fever has broken out also at Tokyo, 3,500 cases having been notified in a few days.

A MUNICIPAL institute of electro-radiology has been founded by the city of Paris at 37, Boulevard St. Marcel, with Dr. Zimmern as director. The indigent inhabitants of Paris and the Seine department will be treated free, and other patients will be required to pay fees according to the scale fixed by the municipal council.

A SYMPATHETIC obituary notice of the late Dr. John Thomson appears in the October issue of the *Archives de médecine des enfants* written by the editor, Dr. Jules Comby.

In the four weeks ending August 14th there were 497 deaths due to automobile accidents in 78 large cities in the United States.

DR. MAURICE ROCH, professor of clinical medicine, has been appointed dean of the medical faculty at Geneva.

THE École d'Anthropologie de Paris will celebrate the fiftieth anniversary of its foundation on November 3rd.

## Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to **THE EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.**

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the **BRITISH MEDICAL JOURNAL** alone unless the contrary be stated. Contributors who wish notice to be taken of their communications should authenticate them with their names not.

Authors desiring REPRINTS of their articles published in the **BRITISH MEDICAL JOURNAL** must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the JOURNAL, should be addressed to the Financial Secretary and Business Manager.

THE TELEPHONE NUMBERS of the British Medical Association and the British Medical Journal are **MUSEUM 9861, 9862, 9863, and 9864** (internal exchange, four lines).

THE TELEGRAPHIC ADDRESSES are:

EDITOR of the **BRITISH MEDICAL JOURNAL**, *Aitology Westcent, London.*

FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate Westcent, London.*

MEDICAL SECRETARY, *Mediscera Westcent, London.*

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Bacillus, Dublin*; telephone: 4737 Dublin), and of the Scottish Office, 6, Drumshugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone: 4361 Central).

## QUERIES AND ANSWERS.

### LEUCOPLAKIA.

"B. A." asks for suggestions for the treatment of leucoplakia, in a case with no suspicion of syphilitic origin.

### ADRENALINE AND GLYCOSURIA.

"I." asks: What is the nature of the glycosuria produced by the administration of adrenaline, and is its continued administration likely to produce or predispose to diabetes?

### RECURRENT BOILS.

"W. L.-G." (Torquay) asks for suggestions for the treatment of a woman, aged 32, who has been suffering from boils for the last eight years, never being free from them for more than two months. She is of good physique; catamenia and bowels regular; no sugar or albumin. The following remedies have been tried: Extraction of teeth for pyorrhoea, vaccines, calcium, yeast, injections of manganese, and stannoxyl—and in desperation, charlatan medicines.

### THE "STRANGE FEVER" OF 1558.

DR. W. JOHNSON SMYTH (Bournemouth) writes: In Dr. Sydney Carter's *History of the English Church and the Reformation* (Longmans, Green and Co.) it is recorded on page 185 that towards the close of Queen Mary's reign, in 1558, no fewer than thirteen bishops and numbers of clergy were carried off by a fever raging at the time. It would be interesting to know if our medical historians can enlighten us as to the nature of this fever—presumably it was a pandemic of some kind. Was it influenza or ague?

\* According to Creighton's *History of Epidemics in Britain*, 1558-59 was a sickly period for all Europe, the diseases being of the types of dysentery, typhus, and influenza. On the Continent 1557 was remarkable for a widely prevalent "pestiferous and contagious sickness." In England "strange agues and fevers" prevailed that year, and with greater severity in 1553, carrying off many of the wealthiest men. The widespread sickness of 1557-58 has been commonly grouped under "influenza," but in using this term Creighton adds that it is "at best a generic

name, and need not commit us to any nosological definition." Again, the term "ague," so often used at that time, is, he says, no more decisive for the nosological character than the term "influenza"; it meant originally a sharp fever (*febris acuta*). In regard to mortality among the clergy, he quotes Stow's statement that in the harvest of 1558 "quartan agues continued in like manner, or more vehemently than they had done the last year passed, wherethrough died many old people and specially priests."

#### INCOME TAX. Cash Basis.

"W. R." purchased a practice many years ago and in the early years paid income tax on the full earning value of the practice, which was, of course, less than the cash value. He has now retired, "and is asked to pay on what he receives."

"\*.\*" We agree that this is incorrect. As from the date he ceased to carry on the practice his income tax liability as a practitioner ceased and he is not liable to tax, in spite of the fact that he is still collecting book debts. If it is contended that these should be thrown back into the earlier years when he was practising, the answer is that receipts should also be thrown back out of those years, and so on, until the ultimate adjustment is reached in the years when he paid on more than his receipts.

#### LETTERS, NOTES, ETC.

##### SUNBURN AND MOSQUITOS.

MANY a summer holiday in the mountains has been spoilt by mosquitos and other biting flies, and by sunburn, which is apt to become a serious matter with some people, especially blondes. Professor J. A. NIXON of Bristol recently told us of some precautions which he had found effective in the Pyrenees this summer. He writes:

My colleague Dr. A. T. Todd suggested that quinine might prevent sunburn, and Mr. E. Lloyd (assistant pharmacist at the Bristol Royal Infirmary) told me that cod-liver oil would keep off mosquitos and other biting flies. The smell of the cod-liver oil may at first be disagreeable, but one gets used to it in a few minutes, and the comfort of being able to go through the Pyrenean forests unbitten and unattended by the usual host of flies is enough to outweigh the disadvantages. Freedom from sunburn added greatly to our enjoyment of the mountains. I had previously seen how quinine protected from the sun's rays in a case of pellagra under Dr. Todd's care. For travelling we packed the collapsible tube containing the ointment inside one of our climbing boots, where it could do no harm if it leaked. The formula is: Quinine acid hydrochloride, 5 parts (dissolved 1 in 2 of water); anhydrous wool fat, 70 parts; cod-liver oil, 25 parts; "ionone," q.s. The quinine is dissolved in water and added to the wool fat, next the cod-liver oil is mixed with it, and finally "ionone" (a violet scent) is put in to disguise the smell of the cod-liver oil.

We have been informed by another friend that cod-liver oil is as effective for oiling the surface of small ponds, water-butts, and so on, to control the development of mosquito larvae as paraffin, and does not make the water distasteful to cattle.

##### JAMES GRAHAM.

DR. GEORGE PERNET (London, W.C.) writes: In the valuable and entertaining quack number published by the BRITISH MEDICAL JOURNAL in 1911 there is an illustration (page 1271) purporting to represent James Graham, the quack, on Adelphi Terrace. But in a little book with the title *Edinburgh Life in the Eighteenth Century* (selected and arranged from "Captain Topham's Letters"; a new edition, but without a date; William Brown, Edinburgh), the same picture appears as "Crossing the North Bridge in a high wind." The stoupe parapet of the bridge fits in with the North Bridge of Auld Reekie; Adelphi Terrace is guarded by railings. These are shown in an old print of Adelphi Terrace by Carey in the possession of the Savage Club.

##### JOHN GRAUNT.

"E. M. L." writes: In "Nova et Vetera" in the JOURNAL of October 9th, on "The Bills of Mortality," it was erroneously stated on p. 645 that Graunt's book on this subject was not published till 1665, yet on p. 646 it is correctly stated that Pepys bought a copy in 1662. There were four editions or impressions of the *Observations* published between 1662 and 1665, all of which seem to have contained the epistle dedicatory to Lord Truro (John Robartes, afterwards Viscount Bandon, Earl of Radnor), which was dated January 22, 1662. The first edition, printed and published by Samuel Smith, was the one which was published as by John Graunt, yet there have not been wanting those who attributed the authorship to Graunt's friend, Sir William Petty. The whole question of the authorship has been exhaustively dealt with by Dr. C. H. Hull of Cornell University in his book, *The Economic Writings of Sir William Petty* (Cambridge University Press, 1899); he came to the conclusion that Graunt was the author of the *Observations*. A strange contradiction is to be found in the second epistle dedicatory to Graunt's book addressed to Sir Robert Moray, President of the Royal Society, in which Graunt states, referring to that society,

"altho I am none of your number, nor have the least ambition to be so, otherwise then (sic) to become able for your service." Yet, on the title page of the same edition (published in 1665), he is described as "John Graunt, Fellow of the Royal Society." Moreover, his name appears on the second page of signatures of the persons who, on December 5th, 1660, resolved to form a society for promoting experimental philosophy, together with those of John Driden (sic), Francis Glisson, the Duke of Buckingham, and other distinguished persons (see "The Signatures in the First Journal Book, etc., with a Preface by Sir Archibald Geikie"), and he was one of the original Fellows elected (May 20th, 1663).

##### ERADICATION OF FLEAS FROM ROOMS.

DR. RAWEL CHAND SURI (Rawalpindi), in reply to the inquiry "P. S. H." (July 31st, p. 235) about the extermination of fleas in old buildings, suggests that burning cresol in the rooms with all apertures closed would be effective. A quantity of 3 oz. required for a room 10 ft. in length, height, and width. As a alternative he advises spraying the room thrice a day for two or three days with "Flit," an insecticide prepared by the Standard Oil Company.

##### CALENDAR REFORM.

FOLLOWING the example of Julius Caesar and Pope Gregory XIII the League of Nations is setting about the reform of the calendar. The recent Assembly received a report on the subject from committee of experts, chiefly representative of academies and observatories, which had been set up by the League's advisor commission on communications and transit. This committee has ignored the more ambitious schemes of reform suggested. It is desired in some quarters that the year should begin on what is now December 22nd, so that the astronomical and civil year may correspond. The committee felt, however, that while this would produce a certain scientific satisfaction, it would involve very great disturbance, and seriously affect comparative economic and social statistics. The committee has therefore confined its attention to methods of securing as much equality as possible in the divisions of the year. The fact that a month may have anything from twenty-eight to thirty-one days is unfortunate from a statistical point of view, and makes constant adjustment necessary in insurance and interest calculations, I mention no others. One method which is favoured by many commercial concerns, including the British railway companies is to have a year of thirteen months, each month having twenty-eight days; but this, while very convenient for monthly statistics would interfere unduly with quarterly and half-yearly reckoning and, moreover, would make a comparison of past and future dates extremely difficult. The committee favours the plan of making each quarter consist of two months of thirty days and a third month of thirty-one days. This would make all the quarters correspond in respect to the days of the week. For example, if January 1st was on a Sunday, February 1st would be on a Tuesday, and March 1st on a Thursday, and all the ensuing months would follow the same order. All these systems, of course, leave out of account one odd day (in leap year two days) and the question where the odd day shall be intercalated is one on which there are many opinions. The majority of opinion would make the odd day the first day of the year, and place it outside the scheme of weeks and months. The committee has also addressed itself to the question of fixing the date of Easter. At present the date of Easter may vary within a period of thirty-five days, which is inconvenient in many respects, leading for instance, to inequality in university terms and in law sittings. It appears from the committee's investigations that no strong objection to change would be raised in any important ecclesiastical quarter, though the Roman Catholic hierarchy would need to be assured that there was a universal advantage before sanctioning such a departure from tradition. The date most convenient for a stabilized Easter is held by the committee to be the second Sunday of April or, better still, to avoid occasional clashing with other festivals, the Sunday following the second Saturday. The report of the committee was blessed in an absent-minded way by the Assembly, and was remitted to the various governments with a suggestion that national committees of inquiry should be set up, representing the various commercial and other interests concerned, and that public opinion should be elicited with a view to arriving at some generally acceptable policy, for which the recommendations of this committee may serve as a starting-point.

##### AN UNDELIVERED BOOK.

A CORRESPONDENT in Southport informs us that on August 20th he paid 7s. 6d. for a book to a man who represented that he was selling books on behalf of the Oxford Press. The book has not been received and letters to the address given on the receipt (W. P. Varsie, 54, Falcon Avenue, Edinburgh) have not been acknowledged. Our correspondent offers no defence for paying the money before receiving the book, but thinks that his experience may serve as a warning to others.

##### VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 42, 43, 44, 45, 48, and 49 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 46 and 47.

A short summary of vacant posts notified in the advertisement column appears in the Supplement at page 175.

*The Harveian Oration*  
ON  
**THE DEBT OF MEDICINE TO THE  
EXPERIMENTAL METHOD  
OF HARVEY.**

DELIVERED BEFORE THE ROYAL COLLEGE OF PHYSICIANS  
ON OCTOBER 18TH, 1926,  
BY

SIR JOHN ROSE BRADFORD, K.C.M.G., P.R.C.P.,  
M.D., D.Sc., F.R.S.

SIR HUMPHRY ROLLESTON and Fellows of the College: I have, as a first duty, to tender to you, Sir, my thanks for entrusting to me the honourable office of delivering, in accordance with the wishes of Harvey, the annual oration commemorating the benefactors of this College. It is a striking tribute to the greatness of Harvey that notwithstanding the lapse of time and notwithstanding the great benefactions received by this College from other pious founders from remote to very recent times, this oration has become more and more a tribute to the unparalleled services rendered by William Harvey, not merely to this College, but to mankind. This result is, no doubt, in part dependent upon the greatness and brilliance of Harvey's discoveries as to the existence of the circulation, and the unravelling of some of the mystery surrounding the heart beat, but it is due still more to the great conceptions he formed as to the proper methods to follow in attempting to understand the facts of Nature. It is probable that it is no exaggeration to say that the most valuable benefaction this College has ever received is Harvey's exhortation to the Fellows and Members of the College to search and study out the secrets of Nature by way of experiment, coupled with the example afforded by his own life's work.

Harvey, like most great men, was of so modest a character that he had little idea of the great place he himself would occupy in the history of science, and this exhortation of his, together with his desire that the Fellows of his beloved College should continue in mutual love and affection amongst themselves, was doubtless only an expression of his wishes for the successful development of this College, and thus indirectly of medicine as a whole.

Successive Harveian orators during the last 200 years have striven to honour his memory and his services in a series of orations dealing with different aspects of his life and work, or with the progress of scientific knowledge since his day, and the influence of this on mankind and on civilization. Scholars have brought before us the state of medical knowledge in his time, and have also vividly portrayed the mode of his life and the conditions under which he worked. We know, thanks to their labours, what manner of man he was, and what was the influence on him of the disturbed time in which he lived. These are matters of perennial interest, and his example of philosophic calm under conditions of great national anxiety cannot fail to be an example to all for all time.

Harvey's life work illustrates, in a remarkable manner, the many-sided character of medicine when considered as a whole, and how the men who promote its advance are often men of wide attainments in many branches of knowledge. His greatness is shown by the fact that, notwithstanding the conditions prevalent in his time, he was able to so free himself from the traditions of the past and the influence of authority and dogma as to lay the foundations of modern science by his insistence on the fundamental importance of experiment and of accuracy of observation. Different sciences afford different opportunities for the use of experiment as a means of discovery, but the founder of the science of physiology had, in his field of study, unlimited scope for this method of advance, as prior to Harvey but little had really been effected by experiment, although it had been used by many, even in ancient times. We reverence Harvey, not only for the foundation of physiology as a science and for showing how its progress is

to be effected, but, as Fellows of this College of Physicians, for making plain the intimate relationship which must exist between medicine, both as a science and as an art, and physiology. Harvey combined in himself the physician and the physiologist. This, with the lapse of time and the progress of knowledge, has become increasingly difficult, and this difficulty is one common, to a greater or less extent, to all branches of knowledge, but more especially when a field of work includes a science and an art. There is some danger of a catastrophe akin to that of the Tower of Babel involving the more narrow specialists of these later days, owing to the rapid development of the new languages required to describe the results achieved in some departments of knowledge.

Although the great developments of knowledge make it more and more difficult for any one individual to have anything approaching complete and detailed information even in one branch, and still more so in more than one, yet there should be, on the other hand, less difficulty in acquiring a fuller grasp of fundamental principles. After all, the magnitude of any scientific discovery is to be measured rather by its influence on the genesis of these fundamental principles, often formulated as so-called laws, than on the mere solution of the particular problem investigated. The so-called physical sciences have had in the past an advantage in this respect over the biological, in that the mathematician, the astronomer, the physicist, and the chemist have had more in common than the morphologist, the physiologist, and the pathologist. But the progress of knowledge is gradually effecting a change in this respect, and it is becoming more and more easy for the followers of the different sides of biology to meet on common ground. It is not only becoming increasingly difficult to draw a hard and fast line between the problems investigated by the physiologist and those of the pathologist, but even the morphologist, whether zoological or botanical, is now pursuing with zeal, purely physiological methods in order to further his science, even on its morphological side. Harvey, as a physiologist, would have rejoiced at these developments if he had known that the colour of an animal and even its form and mass, to say nothing of its sex, were under the influence of, and capable of being modified by, the functional activity of certain glands.

Harvey was, as just stated, a physiologist and a physician who practised his profession, and was daily face to face with urgent and distressing problems, as we all are. We all agree that our improved methods of coping with these problems are ultimately dependent upon his great discovery; and it is a trite observation that medicine must be founded on physiology, and that the study of healthy processes must precede that of morbid ones.

But the debt of the art of medicine to the science of physiology is greater than this, and the value of physiology to medicine is not to be measured merely by the direct practical utility, great as it may be and has been, of individual physiological discoveries, even when these are, like Harvey's, of a truly epoch-making character. The art of medicine must of necessity be reared as a superstructure on the science of medicine unless it is to be indistinguishable from mere empiricism; and the science of medicine, like other sciences, can only be advanced by observation and by experiment. When we reflect on what has been done in the past by the observation of our predecessors, from the most remote to recent times, we cannot fail to record our admiration of the great intellectual qualities that these observers must have possessed to have enabled them to achieve the results obtained. The knowledge of the natural history of disease is a subject of vast importance to the art of medicine, and one that can only be acquired by observation. Nevertheless, as the late Lord Moulton has well said, when we are reduced to observation, science crawls. If we are to treat a disease successfully we must know a great deal more about it than its natural history—that is, its course when it is allowed to pursue its career unchecked. Experiment as a method of furthering the progress of any given science is capable of achieving great results, and—again to quote Lord Moulton—"As soon as you can bring experiment to bear upon a subject you are free, but as long as you can merely observe, your progress is slow. The reason is that experiment is like

cross-examination: you can put the question you want, and Nature always answers it."

Experiment, however, is not equally applicable to all sciences, and from the circumstances it is obvious that in medicine its scope must necessarily be limited. This is, doubtless, one of the reasons why the progress of the science of medicine has been slower than we could wish, but another is to be found in the profound complexity of the problems that have to be solved. This complexity is not only obvious in the consideration of broad general questions, such as the nature and causes of disease, or of individual diseases, but applies often to our daily work of the mere recognition of the nature of the malady in an individual patient. We are often baffled by the complexity of this, and nothing is more common in the experience of practitioners of our art than to find suddenly that what seems simple and obvious is by no means so. The complexity of the problems daily before us is apt to react on the mind of the physician and produce, even in this rather materialistic age, a tendency to regard the phenomena of life, and especially of disease, in an individual, as scarcely subject to the same rigid laws of cause and effect that we all recognize as binding in the physical world. If this belief, even in a modified and attenuated form, is once entertained, it causes a looseness of thought that is most inimical to the real progress of knowledge in medicine; and it is here that the study of physiology and the work of Harvey have rendered the greatest service to medicine. Harvey, by experimental work, by clear thinking, and by accurate observation, laid the foundations of physiology as a science, and those who have followed in his path have continually added to his foundations, so that now no one questions its right to rank as a science, and no one disputes the fundamental proposition that in physiology, as in physics, like causes produce like results. If the excitation of the vagus nerve causes stoppage of the beat of the heart in one case, and acceleration in another, or possibly in the same animal at another time, it is not, as Magendie thought, due to the variability of vital phenomena as such, but is due, as Bernard, the great exponent of "determinisme," taught, to the conditions not being really the same. It is perhaps superfluous to mention such an attitude of mind as regards physiology, but possibly, even now, we are not altogether free from such a way of looking at things in human medicine, and Magendie's way of thinking has, perhaps, some followers. It is, of course, much more simple to render the conditions the same in physiological observations than in medicine, although even in physiology it is often difficult, as the discordant results of many competent observers show. In human medicine the difficulties are infinitely greater, and hence we should regard the results already achieved as a most remarkable monument to the acumen of clinicians, who must, in order to have obtained the results we are familiar with, have been possessed of exceptionally sound scientific methods of observation.

The history of the progress of our knowledge of medicine affords countless instances of the extreme accuracy of observation possessed by the foremost clinicians of the day, but although their observations were often excellent and their descriptions leave little to be added to, their explanations of the observed facts were not of the same value. Variations observed in the course of maladies were often explained in an artificial and non-scientific manner, owing to the want of appreciation of this law that like causes produce like results, and that if the results are different in apparently similar cases, the real explanation is, not some variability on the part of Nature, but that in reality, although the cases seem similar, there is some hitherto undiscovered difference. One type of thinking closes the door to further work and real progress; the other is one of the most fertile causes of discovery. Shrewd clinicians observed, long ago, that some cases of typhoid fever lasted four weeks, others were said to abort in two weeks; hence it was inevitable that a certain vagueness and uncertainty of belief should be entertained with regard to the action of the virus of this disease; and it is difficult not to think that such beliefs react on the mind and influence profoundly our outlook on problems that beset us, and on our methods

of coping with them. The progress of inquiry shows that the differences in the duration of the febrile period of typhoid fever are, at any rate sometimes, due to the differences in the organisms causing the disease, and we now talk of the enteric group, including both typhoid and paratyphoid bacilli. It is quite true that this increase of knowledge does not settle the problem, as there still remains the question of the relation and origin of the paratyphoid group of organisms; but this progress of knowledge has had the effect of demonstrating that the duration of so-called typhoid fever is not a matter, so to speak, of chance, but depends—or may depend—on the specific nature of the organism causing the illness. The fact that one organism causes an illness of four weeks' duration, and another quite distinct but allied one causes an illness of two weeks' duration, is a very different matter, from the point of view of scientific medicine, from a statement that the illness of typhoid fever may last either four weeks or two weeks. The attitude of mind produced by one belief is calculated to cause a certain bewilderment of feeling, and one both of hopelessness and helplessness of arriving at any definite attainment; the other encourages the inquirer to hope that long-continued patient work may reveal, at any rate in part, the mystery, and show that the phenomena of disease, complex as they are, are nevertheless amenable to the same laws and conditions as those governing the biological and physical worlds. Further, the apparent variability of disease becomes, instead of an impediment, a spur to further inquiry and a stimulus to research, and such inquiries are often rewarded by discoveries that add a definiteness to our knowledge that is of the greatest possible value. It would not have been possible for this attitude of mind to be developed in relation to the problems of medicine unless the study of physiology, and of vital processes generally, had been placed on the surest foundations by Harvey by the use of the experimental method, as it is this method, in its many developments, that has enabled us to see that in living things like causes produce like results, and that the exceptions are apparent only, not real.

Further, in the past there has been much theorizing, both in physiology and in medicine, often on very insufficient data. The experimental method has afforded a very certain and conclusive test of the inaccuracy of much work of this nature, and such results, important as they are, are, nevertheless, of a negative character, and have sometimes led to the belief that there is some antagonism between experimental inquiry on the one hand, and the result of observational methods on the other. Doubtless much loose thinking and many erroneous deductions may occur as the result of the direct and immediate transference of experimental animal results to the explanation of the phenomena of human disease, but this, again, arises from neglect of the fundamental principle that the conditions in the two cases are not alike, and also that we constantly think the phenomena of disease to be much simpler than they really are, and are perpetually hankering after cut-and-dried explanations of what are, in reality, exceedingly complex phenomena. Far be it from me to minimize the direct and immediate gains to medical knowledge and to medical practice that have resulted from individual discoveries in experimental physiology, as, for example, the notable discoveries as to the functions of the thyroid and its secretion, and many others. Harveian orators have dealt with these in such an able fashion that it is superfluous to dwell on them, and I would urge to-day that perhaps of even greater importance is what I may call the general effect on medicine of the development of physiology as an exact science, and the influence that this will have, in the course of time, in making the science of medicine as exact and as worthy to be deemed a science as any other branch of natural knowledge. Clinical observation, when carried out by a great mind and in strict accordance with scientific method, has achieved most striking results—results which are entitled to our highest admiration when, as already stated, we consider the extreme difficulty of the problems and the scanty means at our command to solve them. Often, however, the results, great as they are and accurate as they are, lack the precision of detail that sometimes the experimental method is capable of supplying, and then

the experimental method is responsible for the completion of that which has been truly founded by clinical observation.

A striking illustration of this is afforded by the history of the discovery of what is known, shortly, as localization of function in the cerebral cortex. Here the fundamental work was done by that great clinician and profound thinker Hughlings Jackson; and when we reflect that by the study of a very limited number of cases of hemiplegia and of a series of cases of fits, and by the careful correlation of the phenomena observed during life with the lesions found after death, he was able to arrive at the conclusion that voluntary movements were represented in a certain area of the cortex, we have a magnificent example of the accurate and far-reaching deductions that may be drawn by a master mind. Nevertheless, even in such a case as this, the subsequent experimental work was able to give a precision and supply a mass of detail that greatly enhanced the original fundamental discovery. So much is this the case that many came to think that cerebral localization had been discovered solely by the experimental method, whereas the fundamental facts were really the outcome of clinical observation.

The greatness of Jackson's conceptions is well seen in the fact that he recognized that cortical localization was concerned with the representation of movements, and not of muscles, and, indeed, with a special kind of movement—namely, voluntary movement. In the earlier days of experimental work on this subject some confusion was introduced by certain observers falling into the error of looking for so-called centres for the representation of muscles; and it was only later that inhibition of antagonistic muscles, as well as contraction of other muscles, was also recognized as a matter of cortical representation. Anyone who has actually seen the movements called forth by the electrical excitation of the cerebral cortex will experience quite different mental impressions from those he will have felt by watching an epileptiform seizure, perhaps confirmed subsequently by seeing the position and nature of the lesion responsible for it. In the one case there is a definiteness and certainty that in the other is apt to be replaced, at the best, by a feeling of high probability. And yet, if we are to succeed in our endeavours to cope with the facts of nature, we must aim at possessing certain, and not probable, knowledge. It may be that this is often, in our work at present, unattainable, but it is the great thing to aim for in all our work. Perhaps some of our mistakes in the practice of our art arise from not clearly differentiating between what we really know and what is only probable; and sometimes, perhaps, we speak with an apparent certainty about matters that are not, in our present state of knowledge, really as certain as we would like them to be. The touchstone of the experimental method of Harvey is a useful corrective whenever and wherever it may be applied to questions of this nature. The modern physiology of the central nervous system, investigated by the experimental method, affords a striking example of the extraordinary precision of knowledge that may be obtained by the use of this method, and, thanks to it, a flood of light has been thrown on the complex problems of the mechanisms involved in posture, equilibration, co-ordination of movement, and perhaps on the still more complex mechanisms associated with the highest functions of the brain. Nevertheless, in an oration associated with the name of Harvey it may perhaps be possible to illustrate the principles of the profound influence exerted by experimental physiology on medicine by seeking an example in that branch of physiology so closely associated with Harvey—namely, the beat of the heart.

I am not so much concerned to-day with giving a record of individually important discoveries that have been made from time to time whereby our knowledge has been increased and our power of recognizing, and treating with some success, individual diseases, has been extended, but rather with the nature of the conceptions we form of the phenomena of heart disease as we see them clinically in the light of the exact modern physiology of the heart, as revealed by the use of the experimental method of Harvey.

The beat of the heart, from the earliest times to the

present, has been looked upon as emblematic of life, by poets, philosophers, and thinkers, and has always had an element of mystery and awe attached to it. No physician will deny that in disease there is much of apparent mystery in what may be called the natural history, or, if you will, the clinical course, of heart disease; further, that the clinical picture presented by individual cases, even where relatively simple lesions are present, is one with much individual variety, that the phenomena are complex and difficult to analyse, and hence there has been much uncertainty of opinion, both in diagnosis and in treatment. Such differences of opinion existed, not only with reference to questions of interpretation or explanation, but even in reference to what we should now regard as mere questions of fact. There must be some present here to-day who will remember a controversy as to the actual time of occurrence of certain well known murmurs associated with a common valvular disease. When the methods available for clinical observation led to such remarkable differences of opinion among physicians of recognized skill and ability, it is not strange that many keen and able minds should have felt that the problems of medicine were so difficult and so complex that it was beyond their power to really solve them with the means at their disposal; and this attitude of mind is one very inimical to the progress of our science and our art. The method of Harvey of seeking the secrets of nature by way of experiment shed a flood of light on the problems that had baffled those who confined their methods to observation. Not only was this the case, but what is of supreme importance to recognize is the fact that many of the men who in recent times remodelled our conception of the nature of cardiac disease by the fundamental character of their discoveries of the nature of the cardiac beat were men who devoted their lives to the investigation of the facts of nature with no other object in view than that of adding to knowledge for its own sake. Great as their discoveries were, they had no idea of their practical bearing on heart disease, and some of them, indeed, were men who had no knowledge of heart disease as such, and never undertook their work with any idea of adding to our knowledge of heart disease. Further, the discoveries of the pure clinicians, remarkable as they were for the acuteness of their observation, were largely due to making use of the methods and apparatus of the laboratory in the investigation of clinical problems. The polygraph and the electro-cardiogram gave certain and accurate information where previously other methods of observation had led only to the dissemination of views, explanations, and theories of varying degrees of probability. It is one thing to be able to actually demonstrate beyond cavil that the auricle of the human heart in a living patient is in the state known to us as that of fibrillation, and another to talk of lack or failure of compensation, with no clear mental picture of the meaning of the words used. Anyone who has seen a fibrillating auricle in the living animal in the laboratory has a mental picture that is not easily forgotten—a picture of a singularly concrete and definite character, with an element of reality about it that cannot fail to be a useful reminder to him when he stands at the bedside of a patient suffering from the effects of this condition. It is, of course, quite true that the acute clinical observers of the past had recognized the clinical picture produced by this condition, and had described quite accurately some of its manifestations. We can but admire their acumen, but they were necessarily unable, owing to the lack of physiological knowledge and the want of accurate methods, to determine the true cause of the symptoms and to correlate the lesion with its results. Hence the inevitable temptation, to some minds, to speculate and theorize vaguely instead of confining themselves to mere observation, and hence the further elaboration of more and more speculation and ultimately much confusion as to what was speculation and what was firmly established by observation. This has often been most harmful to the real progress of medicine, owing to the development of loose methods of reasoning, and the frequent impossibility of bringing the matter in dispute to a decision by the crucial method of experiment.

The history of the development of our knowledge of fibrillation is singularly interesting as affording a striking example of the experimental method having substituted

17th, 1915, and December 24th, 1917, and received two decorations—the Military Cross on February 18th, 1915 (when he was one of the earliest recipients of that order, founded on January 1st, 1915), and the D.S.O. on January 1st, 1918.

Major Harold Stewart Dickson, R.A.M.C., died of pneumonia in the nursing home at Srinagar, Kashmir, on August 31st, aged 46. He was born on April 16th, 1880, and was educated at Bart's, taking the M.R.C.S. and L.R.C.P. Lond. in 1905. He entered the R.A.M.C. in July, 1909, received a brevet majority in June, 1919, and became major less than two months afterwards—on July 27th, 1919. He was placed on temporary half-pay, on account of ill health, on January 7th, 1921, but rejoined within a year. He served in the war of 1914-18, gaining his brevet as major.

## Medico-Legal.

### A DANGEROUS DRUGS PROSECUTION.

At Marlborough Street Police Court, London, on October 8th, Mr. Cancellor, the stipendiary magistrate, heard summonses preferred by the Director of Public Prosecutions against John Kynaston, whose address was given as Langham House, Regent Street, W., for aiding, abetting, counselling, and procuring Rowland Pawsey to attempt to obtain possession of a dangerous drug—powdered opium—contrary to the provisions of the Dangerous Drugs Act, 1920, and, further, under the Medical Act, 1858, with falsely describing himself as a recognized licentiate in medicine and surgery by the use of the description "M.R.C.S., L.R.C.P. Lond."

Mr. Vincent Evans, for the Director of Public Prosecutions, said the defendant treated a Mr. Pawsey for catarrh, and, in furtherance of the treatment, handed him a prescription. At the top of the prescription were the words "Late R.A.M.C., L.R.C.P., M.R.C.S.," and at the bottom the defendant had signed his name, adding, "Lieutenant-Colonel R.A.M.C., retired, M.R.C.S., L.R.C.P. Lond." As a matter of fact in 1922 his name was removed from the Medical Register by the General Medical Council, and his name was subsequently removed from the registers of the two Colleges in question.

The defendant objected to being referred to as "Mr. Kynaston," saying he was a retired lieutenant-colonel of the R.A.M.C.

Rowland Pawsey, registrar of marriages, Marylebone, cross-examined by the defendant, said he did not ask the defendant to give him a dangerous drug. The witness was aware that the defendant had had a dispute with the General Medical Council, and gathered further that the defendant was no longer on the Medical Register; witness inferred that he had been removed. The defendant had not entered into a conspiracy to "aid, abet, counsel, or procure" the witness to get the drug.

C. Siggers, a chemist of Abbeville Road, said that Mr. Pawsey handed him the prescription. Cross-examined by the defendant, witness said he had no reason to suppose that Mr. Pawsey required the drug for an improper purpose, but, after making inquiries, witness refused to make up the prescription because the defendant's name was not on the Medical Register.

The defendant urged that there was no case whatever to go before a jury. On the first summons he elected to go for trial. The hearing was adjourned for further argument.

## Universities and Colleges.

### UNIVERSITY OF CAMBRIDGE.

THE third examination for medical and surgical degrees will be held from Tuesday, December 14th, to Thursday, December 16th. Part I (Surgery, Midwifery, and Gynaecology) will be held on December 14th, and Part II (Principles and Practice of Medicine, Pathology, and Pharmacology) on December 15th and 16th. The examination will be held on December 14th, 15th, and 16th. The names of candidates for the third M.B. examination and for the M.Chir. examination should be sent to the Registry on or before October 26th.

### UNIVERSITY OF SHEFFIELD.

Dr. J. H. BLAKELOCK, M.Sc., M.B., Ch.B. (Sheff.), has been appointed to the post of assistant bacteriologist.

### ROYAL COLLEGE OF SURGEONS OF ENGLAND.

THE annual meeting of Fellows and Members will take place at the College, Lincoln's Inn Fields, on Thursday, November 18th, at 3 p.m.

Copies of the report to be presented can be obtained by any Fellow and Member on application to the Secretary, from whom copies of the agenda (to be issued on or after November 12th) can also be obtained.

### ROYAL FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW.

THE following, after examination, have been admitted as Fellows of the Royal Faculty of Physicians and Surgeons of Glasgow:

|                |                    |
|----------------|--------------------|
| A. Barr, A. F. | D. Blakely, J. M.  |
| Christie       | W. D. MacFarlane   |
| F. G. Mc       | G. T. Mowat, W. A. |
| Sewell, H. L.  | Whittingham, J. M. |
| Young, R. F.   |                    |

## Medical News.

THE minutes of the evidence taken before the Royal Commission on Lunacy and Mental Disorder have been published in three volumes. The first volume includes the evidence taken between October 7th, 1924, and February 10th, 1925, and the second that between February 24th and December 11th, 1925; these two parts are published at one guinea each net. The third volume contains the index and appendices and is published at 10s. 6d. net. The three volumes may be obtained from H.M. Stationery Office, Adastral House, Kingsway, W.C.2; York Street, Manchester; 1, St. Andrew's Crescent, Cardiff; 120, George Street, Edinburgh; or through any bookseller.

At the quarterly meeting of the Grand Council of the British Empire Cancer Campaign, on October 12th, the chairman of the Finance Committee, Sir Richard Garton, urged the necessity for a sustained effort to obtain adequate funds to meet the increasing calls for assistance in researches into the cause of cancer. Mr. J. P. Lockhart-Mummery, chairman of the Executive Committee, announced that the visits of the members of the Intelligence Committee to the principal American and Continental cancer research laboratories would shortly terminate, and that reports on the most recent work on cancer outside the British Empire would be submitted to the Grand Council. Lieut.-General Sir John Goodwin reported that additional county committees were being formed in Buckinghamshire, Berkshire, Cornwall, Durham, Hampshire, Lincoln, Norfolk, Nottingham, Sussex, and Surrey. Sir William Milligan and Sir Robert Jones were elected members of the Grand Council, and Professor Leiper was appointed a member of the Scientific Advisory Committee of the Campaign in place of the late Sir William Leishman.

TICKET holders for the annual service of the Guild of St. Luke, at Westminster Abbey, on October 17th, are requested to be at the West Cloister door not later than 6.15 p.m.

THE fiftieth anniversary dinner of the Cambridge Graduates' Club of St. Bartholomew's Hospital will be held at King Edward VII Rooms, Hotel Victoria, Northumberland Avenue, on Wednesday, November 10th, with Sir Humphry Rolleston, Bt., K.C.B., in the chair. The honorary secretaries are Dr. H. N. Burroughes and Mr. R. M. Vick.

THE annual dinner of past and present students of University College Hospital will be held at the Hotel Cecil, Strand, W.C., on Wednesday, October 27th. Dr. Philip D. Turner, will take the chair at 7.30 p.m. Tickets, price 12s. 6d. (not including wine), may be obtained from the honorary secretaries, Mr. Gwynne Williams, F.R.C.S., and Dr. F. M. R. Walshe, University College Hospital Medical School.

THE old students' dinner of St. Thomas's Hospital will be held at the Hotel Victoria, Northumberland Avenue, London, on Friday, October 29th. Dr. R. Percy Smith will take the chair at 7.30 p.m.

SIR ARTHUR STANLEY will deliver the presidential address at the meeting of the Incorporated Association of Hospital Officers to be held at 28, Bedford Square, W.C.1, on Wednesday, October 27th, at 7 p.m.

A NEW series of post-graduate clinics arranged by the University of Sheffield commences to-day (Friday), October 15th, at 3.30 p.m., when Mr. Brocman lectures on conditions simulating the acute abdomen. The meetings, which take place at the Royal Infirmary, Sheffield, will be continued on succeeding Fridays up to and including Friday, December 17th, at the same hour.

AT the meeting of the Post-Graduate Hostel at the Imperial Hotel, Russell Square, W.C.1, on Tuesday, October 19th, at 9 p.m., Mr. Frank Kidd will open a discussion on pyelonephritis. On Wednesday, October 20th, at 9 p.m., Mr. J. P. Lockhart-Mummery will discuss the prognosis of rectal cancer. All medical practitioners are cordially invited.

THE second of the series of lectures on emergencies in medicine and surgery organized by the Fellowship of Medicine will be delivered by Mr. Joseph Adams on acute appendicitis on October 21st, at 5 p.m., in the lecture hall of the Medical Society, 11, Chandos Street, W., and on the same day a special lecture demonstration on cataract will be given by Mr. A. Caddy at the Royal Westminster Ophthalmic Hospital at 5 p.m. Both lecture and demonstration are open to members of the medical profession without fee. From November 1st to 13th there will be a course for general practitioners at the Hampstead General Hospital in medicine, surgery, and the specialties; and from November 1st throughout the month a course in venereal diseases at the London Lock Hospital. From November 15th to December 4th a course in gynaecology will be held at the Royal Waterloo Hospital; from November 15th to December 11th a course in dermatology, including pathology if desired, at St. John's Hospital; from November 22nd to December 18th a late afternoon course in

neurology at the West End Hospital for Nervous Diseases; from November 29th to December 11th a course in diseases of the chest at the Victoria Park Hospital; from November 22nd to 27th a course in proctology at St. Mark's Hospital; and from November 22nd a course for practitioners at the London Temperance Hospital. Copies of all syllabuses, the General Course Programme of the Fellowship, and its Journal, may be obtained from the Secretary of the Fellowship, 1, Wimpole Street, W.1.

PROFESSOR DR. C. RASCH of Copenhagen will give an address on the effect of light on the skin and skin diseases, at the meeting of the Dermatological Section of the Royal Society of Medicine, 1, Wimpole Street, at 5 p.m., on Thursday, October 21st.

THE annual meeting of the National Association of Insurance Committees will be held at the Hearts of Oak Buildings, Euston Road, N.W.1, on October 21st and 22nd and if necessary October 23rd.

A MATINÉE in aid of the funds of the Tavistock Clinic, the objects of which were described in the Educational Number of September 4th, 1926 (p. 453), will be given, by permission of the Co-optimists, at His Majesty's Theatre on Friday next (October 22nd), at 2.30 p.m. Particulars can be obtained from the Honorary Secretary of the Tavistock Clinic, 51, Tavistock Square, W.C.1.

THE Royal Sanitary Institute will hold its thirty-eighth congress at Hastings next July. The Home Secretary, Sir William Joynson-Hicks, Bt., M.P., will be president. In connexion with it there will be a health exhibition.

UNDER the housing schemes undertaken by the London County Council since the war the number of houses and tenements completed up to the end of September is 14,542 (more than half of them at Becontree), and 4,344 houses and tenements are at present under construction.

AT the September matriculation of the University of London there were 40 successful candidates in the first division and 380 in the second division; 40 took the supplementary certificate in Latin, 5 in mathematics, and one each in Greek, chemistry, mechanics, French, and music.

A PORTABLE x-ray equipment has been designed in the research department, Woolwich, for the examination of aeroplanes. The details and drawings are published in "R.D. Report No. 68" by H.M. Stationery Office, with illustrations and working drawings, and may be of interest to medical radiologists.

DR. A. J. MARTIN, on his departure from Bloxwich, where he practised for thirty-two years, has been presented by his friends and patients with a bookcase, a clock, and a gold cigarette case.

A TABLET to the memory of the late Dr. Claude B. Ker placed in the entrance hall of the Edinburgh City Hospital, Colinton, was unveiled recently by Lady Sleigh. The memorial, which is of marble and bronze, bears in relief a portrait of Dr. Ker and an inscription recording that he was superintendent of the hospital from 1897 to 1925.

OWING to the further generosity of Mr. George Buckston Browne, the sum of £1,000 has been added to the Memorial Prize Fund of the Harveian Society of London which bears his name. The council of the society will therefore be able to give more valuable prizes for successful essays.

THE fifth Rumanian Congress of Oto-rhino-laryngology will be held at Bucarest, under the presidency of Dr. A. Costiniu, on October 24th and 25th, when the following subjects will be discussed: adenoids in their endocrine aspects, introduced by Koleszar, Vasilin, and Tatarsky; deaf-mutism in Rumania, introduced by Daraban. Further information can be obtained from the general secretary, Dr. Mayersohn, 81, Calea Musilov, Bucarest.

COURSES of lectures in German are arranged by the University of Vienna throughout the year in connexion with post-graduate medical instruction. Special international courses are to be held in February, June, September, and November, each lasting a fortnight, and dealing with the recent work in various specialties. Syllabuses of both these courses may be obtained, free of charge, from the Kurs Bureau of the Vienna Faculty of Medicine, Schlösselgasse 22, Vienna VIII.

DR. CLAUD SCHILLING, professor at the Robert Koch Institute for Infectious Diseases, Berlin, has been appointed a member of the Malaria Commission of the League of Nations.

THE present epidemic of typhoid fever in Hanover is attributed to infection of one of the three waterworks supplying the town. Up to September 17th 1,504 patients, of whom 42 have died, have been admitted to hospitals, but the number of cases nursed at home is not yet known. A severe epidemic of typhoid fever has broken out also at Tokyo, 3,500 cases having been notified in a few days.

A MUNICIPAL institute of electro-radiology has been founded by the city of Paris at 37, Boulevard St. Marcel, with Dr. Zimmern as director. The indigent inhabitants of Paris and the Seine department will be treated free, and other patients will be required to pay fees according to the scale fixed by the municipal council.

A SYMPATHETIC obituary notice of the late Dr. John Thomson appears in the October issue of the *Archives de médecine des enfants* written by the editor, Dr. Jules Comby.

IN the four weeks ending August 14th there were 497 deaths due to automobile accidents in 78 large cities in the United States.

DR. MAURICE ROCH, professor of clinical medicine, has been appointed dean of the medical faculty at Geneva.

THE École d'Anthropologie de Paris will celebrate the fiftieth anniversary of its foundation on November 3rd.

## Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to **THE EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.**

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the *JOURNAL*, should be addressed to the Financial Secretary and Business Manager.

The TELEPHONE NUMBERS of the British Medical Association and the *British Medical Journal* are MUSEUM 9861, 9862, 9863, and 9864 (internal exchange, four lines).

THE TELEGRAPHIC ADDRESSES are:

EDITOR of the *British Medical Journal*, Aitiology Westcent, London.

FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), Articulate Westcent, London.

MEDICAL SECRETARY, Medisecra Westcent, London.

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegram: *Incillus, Dublin*; telephone: 4737 Dublin), and of the Scottish Office, 6, Drumshugh Gardens, Edinburgh (telegram: *Associate, Edinburgh*; telephone: 4361 Central).

## QUERIES AND ANSWERS.

### LEUCOPLAKIA.

"B. A." asks for suggestions for the treatment of leucoplakia, in a case with no suspicion of syphilitic origin.

### ADRENALINE AND GLYCOSURIA.

"I." asks: What is the nature of the glycosuria produced by the administration of adrenaline, and is its continued administration likely to produce or predispose to diabetes?

### RECURRENT BOILS.

"W. L.-C." (Torquay) asks for suggestions for the treatment of a woman, aged 32, who has been suffering from boils for the last eight years, never being free from them for more than two months. She is of good physique; catamenia and bowels regular; no sugar or albumin. The following remedies have been tried: Extraction of teeth for pyorrhoea, vaccines, calcium, yeast, injections of manganese, and stannoxyl—and in desperation, charlatan medicines.

### THE "STRANGE FEVER" OF 1558.

DR. W. JOHNSON SMYTH (Bournemouth) writes: In Dr. Sydney Carter's *History of the English Church and the Reformation* (Longmans, Green and Co.) it is recorded on page 185 that towards the close of Queen Mary's reign, in 1558, no fewer than thirteen bishops and numbers of clergy were carried off by a fever raging at the time. It would be interesting to know if our medical historians can enlighten us as to the nature of this fever—presumably it was a pandemic of some kind. Was it influenza or ague?

\* According to Creighton's *History of Epidemics in Britain*, 1555-58 was a sickly period for all Europe, the diseases being of the types of dysentery, typhus, and influenza. On the Continent 1557 was remarkable for a widely prevalent "pestiferous and contagious sickness." In England "strange agues and fevers" prevailed that year, and with greater severity in 1558, carrying off many of the wealthiest men. The widespread sickness of 1557-58 has been commonly grouped under "influenza," but in using this term Creighton adds that it is "at best a generic

name, and need not commit us to any nosological definition." Again, the term "ague," so often used at that time, is, he says, no more decisive for the nosological character than the term "influenza"; it meant originally a sharp fever (*febris acuta*). In regard to mortality among the clergy, he quotes Stow's statement that in the harvest of 1558 "quartan agues continued in like manner, or more vehemently than they had done the last year passed, wherethrough died many old people and specially priests."

#### INCOME TAX.

##### Cash Basis.

"W. R." purchased a practice many years ago and in the early years paid income tax on the full earning value of the practice, which was, of course, less than the cash value. He has now retired, "and is asked to pay on what he receives."

"We agree that this is incorrect. As from the date he ceased to carry on the practice his income tax liability as a practitioner ceased and he is not liable to tax, in spite of the fact that he is still collecting book debts. If it is contended that these should be thrown back into the earlier years when he was practising, the answer is that receipts should also be thrown back out of those years, and so on, until the ultimate adjustment is reached in the years when he paid on more than his receipts."

#### LETTERS, NOTES, ETC.

##### SUNBURN AND MOSQUITOS.

MANY a summer holiday in the mountains has been spoiled by mosquitos and other biting flies, and by sunburn, which is apt to become a serious matter with some people, especially blondes. Professor J. A. NIXON of Bristol recently told us of some precautions which he had found effective in the Pyrenees this summer. He writes:

My colleague Dr. A. T. Todd suggested that quinine might be used, and Mr. E. Lloyd (assistant pharmacist at the time) told me that cod-liver oil would keep off the flies. The smell of the cod-liver oil is not agreeable, but one gets used to it in a few minutes, and the comfort of being able to go through the Pyrenean forests unbitten and unattended by the usual host of flies is enough to outweigh the disadvantages. Freedom from sunburn added greatly to our enjoyment of the mountains. I had previously seen how quinine protected from the sun's rays in a case of pellagra under Dr. Todd's care. For travelling we packed the collapsible tube containing the ointment inside one of our climbing boots, where it could do no harm if it leaked. The formula is: Quinine acid hydrochloride, 5 parts (dissolved in 2 of water); anhydrous wool fat, 70 parts; cod-liver oil, 25 parts; "ionone," q.s. The quinine is dissolved in water and added to the wool fat, next the cod-liver oil is mixed with it, and finally "ionone" (a violet scent) is put in to disguise the smell of the cod-liver oil.

We have been informed by another friend that cod-liver oil is as effective for oiling the surface of small ponds, water-butts, and so on, to control the development of mosquito larvae as paraffin, and does not make the water distasteful to cattle.

##### JAMES GRAHAM.

DR. GEORGE PERNET (London, W.C.) writes: In the valuable and entertaining quack number published by the BRITISH MEDICAL JOURNAL in 1911 there is an illustration (page 1271) purporting to represent James Graham, the quack, on Adelphi Terrace. But in a little book with the title *Edinburgh Life in the Eighteenth Century* (selected and arranged from "Captain Topham's Letters"; a new edition, but without a date; William Brown, Edinburgh), the same picture appears as "Crossing the North Bridge in a high wind." The stoupe parapet of the bridge fits in with the North Bridge of Auld Reekie; Adelphi Terrace is guarded by railings. These are shown in an old print of Adelphi Terrace by Carey in the possession of the Savage Club.

##### JOHN GRAUNT.

"E. M. L." writes: In "Nova et Vetera" in the JOURNAL of October 9th, on "The Bills of Mortality," it was erroneously stated on p. 645 that Graunt's book on this subject was not published till 1665, yet on p. 646 it is correctly stated that Pepys bought a copy in 1662. There were four editions or impressions of the book between 1662 and 1665, all of which were dedicated to Lord Truro (John and Earl of Radnor).

The edition published by Samuel Pepys on the *Weekly Bills of Mortality*, also in 1665, was published as by John Graunt, yet there have not been wanting those who attributed the authorship to Graunt's friend, Sir William Petty. The whole question of the authorship has been exhaustively dealt with by Dr. C. H. Hull of Cornell University in his book, *The Economic Writings of Sir William Petty* (Cambridge University Press, 1899); he came to the conclusion that Graunt was the author of the *Observations*. A strange contradiction is to be found in the second epistle dedicatory to Graunt's book addressed to Sir Robert Moray, President of the Royal Society, in which Graunt states, referring to that society,

"altho I am none of your number, nor have the least ambition to be so, otherwise then [sic] to become able for your service." Yet, on the title page of the same edition (published in 1665), he is described as "John Graunt, Fellow of the Royal Society." Moreover, his name appears on the second page of signatures of the persons who, on December 5th, 1660, resolved to form a society for promoting experimental philosophy, together with those of John Driden (sic), Francis Glisson, the Duke of Buckingham, and other distinguished persons (see "The Signatures in the First Journal Book, etc., with a Preface by Sir Archibald Geikie"), and he was one of the original Fellows elected on May 20th, 1663.

##### DESTRUCTION OF FLEAS FROM ROOMS.

DR. RAWEL C. in reply to the inquiry by "P. S. H." re extermination of fleas in old buildings, suggests that cresol in the rooms with all apertures closed would be effective. A quantity of 3oz. is required for a room 10 ft. in length, height, and width. As an alternative he advises spraying the room thrice a day for two or three days with "Flit," an insecticide prepared by the Standard Oil Company.

##### CALENDAR REFORM.

FOLLOWING the example of Julius Caesar and Pope Gregory XIII, the League of Nations is setting about the reform of the calendar. The recent Assembly received a report on the subject from a committee of experts, chiefly representative of academies and observatories, which had been set up by the League's advisory commission on communications and transit. This committee has ignored the more ambitious schemes of reform suggested. It is desired in some quarters that the year should begin on what is now December 22nd, so that the astronomical and civil year may correspond. The committee felt, however, that while this would produce a certain scientific satisfaction, it would involve very great disturbance, and seriously affect comparative economic and social statistics. The committee has therefore confined its attention to methods of securing as much equality as possible in the divisions of the year. The fact that a month may have anything from twenty-eight to thirty-one days is unfortunate from a statistical point of view, and makes constant adjustment necessary in insurance and interest calculations, to mention no others. One method which is favoured by many commercial concerns, including the British railway companies, is to have a year of thirteen months, each month having twenty-eight days; but this, while very convenient for monthly statistics, would interfere unduly with quarterly and half-yearly reckonings, and, moreover, would make a comparison of past and future dates extremely difficult. The committee favours the plan of making each quarter consist of two months of thirty days and a third month of thirty-one days. This would make all the quarters correspond in respect to the days of the week. For example, if January 1st was on a Sunday, February 1st would be on a Tuesday, and March 1st on a Thursday, and all the ensuing months would follow the same order. All these systems, of course, would add a day (in leap year two days), on which there are many suggestions.

The majority of opinions would make the odd day the first day of the year, and place it outside the scheme of weeks and months. The committee has also addressed itself to the question of fixing the date of Easter. At present the date of Easter may vary within a period of thirty-five days, which is inconvenient in many respects, leading, for instance, to inequality in university terms and in law sittings. It appears from the committee's investigations that no strong objection to change would be raised in any important ecclesiastical quarter, though the Roman Catholic hierarchy would need to be assured that there was a universal advantage before sanctioning such a departure from tradition. The date most convenient for a stabilized Easter is held by the committee to be the second Sunday of April or, better still, to avoid occasional clashing with other festivals, the Sunday following the second Saturday. The report of the committee was blessed in an absent-minded way by the Assembly, and was remitted to the various governments with a suggestion that national committees of inquiry should be set up, representing the various commercial and other interests concerned, and that public opinion should be elicited with a view to arriving at some generally acceptable policy, for which the recommendations of this committee may serve as a starting-point.

##### AN UNDELIVERED BOOK.

A CORRESPONDENT in Southport informs us that on August 23rd he paid 7s. 6d. for a book to a man who represented that he was selling books on behalf of the Oxford Press. The book has not been received and letters to the address given on the receipt (W. P. Varsie, 54, Falcon Avenue, Edinburgh) have not been acknowledged. Our correspondent offers no defence for paying the money before receiving the book, but thinks that his experience may serve as a warning to others.

##### VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 42, 43, 44, 45, 48, and 49 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 46 and 47. A short summary of vacant posts notified in the advertisement column appears in the Supplement at page 175.

**The Harveian Oration**  
ON  
**THE DEBT OF MEDICINE TO THE  
EXPERIMENTAL METHOD  
OF HARVEY.**

DELIVERED BEFORE THE ROYAL COLLEGE OF PHYSICIANS  
ON OCTOBER 18TH, 1926,  
BY

SIR JOHN ROSE BRADFORD, K.C.M.G., P.R.C.P.,  
M.D., D.Sc., F.R.S.

SIR HUMPHRY ROLLESTON and Fellows of the College: I have, as a first duty, to tender to you, Sir, my thanks for entrusting to me the honourable office of delivering, in accordance with the wishes of Harvey, the annual oration commemorating the benefactors of this College. It is a striking tribute to the greatness of Harvey that notwithstanding the lapse of time and notwithstanding the great benefactions received by this College from other pious founders from remote to very recent times, this oration has become more and more a tribute to the unparalleled services rendered by William Harvey, not merely to this College, but to mankind. This result is, no doubt, in part dependent upon the greatness and brilliance of Harvey's discoveries as to the existence of the circulation, and the unravelling of some of the mystery surrounding the heart beat, but it is due still more to the great conceptions he formed as to the proper methods to follow in attempting to understand the facts of Nature. It is probable that it is no exaggeration to say that the most valuable benefaction this College has ever received is Harvey's exhortation to the Fellows and Members of the College to search and study out the secrets of Nature by way of experiment, coupled with the example afforded by his own life's work.

Harvey, like most great men, was of so modest a character that he had little idea of the great place he himself would occupy in the history of science, and this exhortation of his, together with his desire that the Fellows of his beloved College should continue in mutual love and affection amongst themselves, was doubtless only an expression of his wishes for the successful development of this College, and thus indirectly of medicine as a whole.

Successive Harveian orators during the last 200 years have striven to honour his memory and his services in a series of orations dealing with different aspects of his life and work, or with the progress of scientific knowledge since his day, and the influence of this on mankind and on civilization. Scholars have brought before us the state of medical knowledge in his time, and have also vividly portrayed the mode of his life and the conditions under which he worked. We know, thanks to their labours, what manner of man he was, and what was the influence on him of the disturbed time in which he lived. These are matters of perennial interest, and his example of philosophic calm under conditions of great national anxiety cannot fail to be an example to all for all time.

Harvey's life work illustrates, in a remarkable manner, the many-sided character of medicine when considered as a whole, and how the men who promote its advance are often men of wide attainments in many branches of knowledge. His greatness is shown by the fact that, notwithstanding the conditions prevalent in his time, he was able to so free himself from the traditions of the past and the influence of authority and dogma as to lay the foundations of modern science by his insistence on the fundamental importance of experiment and of accuracy of observation. Different sciences afford different opportunities for the use of experiment as a means of discovery, but the founder of the science of physiology had, in his field of study, unlimited scope for this method of advance, as prior to Harvey but little had really been effected by experiment, although it had been used by many, even in ancient times. We reverence Harvey, not only for the foundation of physiology as a science and for showing how its progress is

to be effected, but, as Fellows of this College of Physicians, for making plain the intimate relationship which must exist between medicine, both as a science and as an art, and physiology. Harvey combined in himself the physician and the physiologist. This, with the lapse of time and the progress of knowledge, has become increasingly difficult, and this difficulty is one common, to a greater or less extent, to all branches of knowledge, but more especially when a field of work includes a science and an art. There is some danger of a catastrophe akin to that of the Tower of Babel involving the more narrow specialists of these later days, owing to the rapid development of the new languages required to describe the results achieved in some departments of knowledge.

Although the great developments of knowledge make it more and more difficult for any one individual to have anything approaching complete and detailed information even in one branch, and still more so in more than one, yet there should be, on the other hand, less difficulty in acquiring a fuller grasp of fundamental principles. After all, the magnitude of any scientific discovery is to be measured rather by its influence on the genesis of these fundamental principles, often formulated as so-called laws, than on the mere solution of the particular problem investigated. The so-called physical sciences have had in the past an advantage in this respect over the biological, in that the mathematician, the astronomer, the physicist, and the chemist have had more in common than the morphologist, the physiologist, and the pathologist. But the progress of knowledge is gradually effecting a change in this respect, and it is becoming more and more easy for the followers of the different sides of biology to meet on common ground. It is not only becoming increasingly difficult to draw a hard and fast line between the problems investigated by the physiologist and those of the pathologist, but even the morphologist, whether zoological or botanical, is now pursuing with zeal, purely physiological methods in order to further his science, even on its morphological side. Harvey, as a physiologist, would have rejoiced at these developments if he had known that the colour of an animal and even its form and mass, to say nothing of its sex, were under the influence of, and capable of being modified by, the functional activity of certain glands.

Harvey was, as just stated, a physiologist and a physician who practised his profession, and was daily face to face with urgent and distressing problems, as we all are. We all agree that our improved methods of coping with these problems are ultimately dependent upon his great discovery; and it is a trite observation that medicine must be founded on physiology, and that the study of healthy processes must precede that of morbid ones.

But the debt of the art of medicine to the science of physiology is greater than this, and the value of physiology to medicine is not to be measured merely by the direct practical utility, great as it may be and has been, of individual physiological discoveries, even when these are, like Harvey's, of a truly epoch-making character. The art of medicine must of necessity be reared as a superstructure on the science of medicine unless it is to be indistinguishable from mere empiricism; and the science of medicine, like other sciences, can only be advanced by observation and by experiment. When we reflect on what has been done in the past by the observation of our predecessors, from the most remote to recent times, we cannot fail to record our admiration of the great intellectual qualities that these observers must have possessed to have enabled them to achieve the results obtained. The knowledge of the natural history of disease is a subject of vast importance to the art of medicine, and one that can only be acquired by observation. Nevertheless, as the late Lord Moulton has well said, when we are reduced to observation, science crawls. If we are to treat a disease successfully we must know a great deal more about it than its natural history—that is, its course when it is allowed to pursue its career unchecked. Experiment as a method of furthering the progress of any given science is capable of achieving great results, and—again to quote Lord Moulton—"As soon as you can bring experiment to bear upon a subject you are free, but as long as you can merely observe, your progress is slow. The reason is that experiment is like

cross-examination: you can put the question you want, and Nature always answers it."

Experiment, however, is not equally applicable to all sciences, and from the circumstances it is obvious that in medicine its scope must necessarily be limited. This is, doubtless, one of the reasons why the progress of the science of medicine has been slower than we could wish, but another is to be found in the profound complexity of the problems that have to be solved. This complexity is not only obvious in the consideration of broad general questions, such as the nature and causes of disease, or of individual diseases, but applies often to our daily work of the mere recognition of the nature of the malady in an individual patient. We are often baffled by the complexity of this, and nothing is more common in the experience of practitioners of our art than to find suddenly that what seems simple and obvious is by no means so. The complexity of the problems daily before us is apt to react on the mind of the physician and produce, even in this rather materialistic age, a tendency to regard the phenomena of life, and especially of disease, in an individual, as scarcely subject to the same rigid laws of cause and effect that we all recognize as binding in the physical world. If this belief, even in a modified and attenuated form, is once entertained, it causes a looseness of thought that is most inimical to the real progress of knowledge in medicine; and it is here that the study of physiology and the work of Harvey have rendered the greatest service to medicine. Harvey, by experimental work, by clear thinking, and by accurate observation, laid the foundations of physiology as a science, and those who have followed in his path have continually added to his foundations, so that now no one questions its right to rank as a science, and no one disputes the fundamental proposition that in physiology, as in physics, like causes produce like results. If the excitation of the vagus nerve causes stoppage of the beat of the heart in one case, and acceleration in another, or possibly in the same animal at another time, it is not, as Magendie thought, due to the variability of vital phenomena as such, but is due, as Bernard, the great exponent of "determinisme," taught, to the conditions not being really the same. It is perhaps superfluous to mention such an attitude of mind as regards physiology, but possibly, even now, we are not altogether free from such a way of looking at things in human medicine, and Magendie's way of thinking has, perhaps, some followers. It is, of course, much more simple to render the conditions the same in physiological observations than in medicine, although even in physiology it is often difficult, as the discordant results of many competent observers show. In human medicine the difficulties are infinitely greater, and hence we should regard the results already achieved as a most remarkable monument to the acumen of clinicians, who must, in order to have obtained the results we are familiar with, have been possessed of exceptionally sound scientific methods of observation.

The history of the progress of our knowledge of medicine affords countless instances of the extreme accuracy of observation possessed by the foremost clinicians of the day, but although their observations were often excellent and their descriptions leave little to be added to, their explanations of the observed facts were not of the same value. Variations observed in the course of maladies were often explained in an artificial and non-scientific manner, owing to the want of appreciation of this law that like causes produce like results, and that if the results are different in apparently similar cases, the real explanation is, not some variability on the part of Nature, but that in reality, although the cases seem similar, there is some hitherto undiscovered difference. One type of thinking closes the door to further work and real progress; the other is one of the most fertile causes of discovery. Shrewd clinicians observed, long ago, that some cases of typhoid fever lasted four weeks, others were said to abort in two weeks; hence it was inevitable that a certain vagueness and uncertainty of belief should be entertained with regard to the action of the virus of this disease; and it is difficult not to think that such beliefs react on the mind and influence profoundly our outlook on problems that beset us, and on our methods

of coping with them. The progress of inquiry shows that the differences in the duration of the febrile period of typhoid fever are, at any rate sometimes, due to the differences in the organisms causing the disease, and we now talk of the enteric group, including both typhoid and paratyphoid bacilli. It is quite true that this increase of knowledge does not settle the problem, as there still remains the question of the relation and origin of the paratyphoid group of organisms; but this progress of knowledge has had the effect of demonstrating that the duration of so-called typhoid fever is not a matter, so to speak, of chance, but depends—or may depend—on the specific nature of the organism causing the illness. The fact that one organism causes an illness of four weeks' duration, and another quite distinct but allied one causes an illness of two weeks' duration, is a very different matter, from the point of view of scientific medicine, from a statement that the illness of typhoid fever may last either four weeks or two weeks. The attitude of mind produced by one belief is calculated to cause a certain bewilderment of feeling, and one both of hopelessness and helplessness of arriving at any definite attainment; the other encourages the inquirer to hope that long-continued patient work may reveal, at any rate in part, the mystery, and show that the phenomena of disease, complex as they are, are nevertheless amenable to the same laws and conditions as those governing the biological and physical worlds. Further, the apparent variability of disease becomes, instead of an impediment, a spur to further inquiry and a stimulus to research, and such inquiries are often rewarded by discoveries that add a definiteness to our knowledge that is of the greatest possible value. It would not have been possible for this attitude of mind to be developed in relation to the problems of medicine unless the study of physiology, and of vital processes generally, had been placed on the surest foundations by Harvey by the use of the experimental method, as it is this method, in its many developments, that has enabled us to see that in living things like causes produce like results, and that the exceptions are apparent only, not real.

Further, in the past there has been much theorizing, both in physiology and in medicine, often on very insufficient data. The experimental method has afforded a very certain and conclusive test of the inaccuracy of much work of this nature, and such results, important as they are, are, nevertheless, of a negative character, and have sometimes led to the belief that there is some antagonism between experimental inquiry on the one hand, and the result of observational methods on the other. Doubtless much loose thinking and many erroneous deductions may occur as the result of the direct and immediate transference of experimental animal results to the explanation of the phenomena of human disease, but this, again, arises from neglect of the fundamental principle that the conditions in the two cases are not alike, and also that we constantly think the phenomena of disease to be much simpler than they really are, and are perpetually hankering after cut-and-dried explanations of what are, in reality, exceedingly complex phenomena. Far be it from me to minimize the direct and immediate gains to medical knowledge and to medical practice that have resulted from individual discoveries in experimental physiology, as, for example, the notable discoveries as to the functions of the thyroid and its secretion, and many others. Harveian orators have dealt with these in such an able fashion that it is superfluous to dwell on them, and I would urge to-day that perhaps of even greater importance is what I may call the general effect on medicine of the development of physiology as an exact science, and the influence that this will have, in the course of time, in making the science of medicine as exact and as worthy to be deemed a science as any other branch of natural knowledge. Clinical observation, when carried out by a great mind and in strict accordance with scientific method, has achieved most striking results—results which are entitled to our highest admiration when, as already stated, we consider the extreme difficulty of the problems and the scanty means at our command to solve them. Often, however, the results, great as they are and accurate as they are, lack the precision of detail that sometimes the experimental method is capable of supplying, and then

the experimental method is responsible for the completion of that which has been truly founded by clinical observation.

A striking illustration of this is afforded by the history of the discovery of what is known, shortly, as localization of function in the cerebral cortex. Here the fundamental work was done by that great clinician and profound thinker Hughlings Jackson; and when we reflect that by the study of a very limited number of cases of hemiplegia and of a series of cases of fits, and by the careful correlation of the phenomena observed during life with the lesions found after death, he was able to arrive at the conclusion that voluntary movements were represented in a certain area of the cortex, we have a magnificent example of the accurate and far-reaching deductions that may be drawn by a master mind. Nevertheless, even in such a case as this, the subsequent experimental work was able to give a precision and supply a mass of detail that greatly enhanced the original fundamental discovery. So much is this the case that many came to think that cerebral localization had been discovered solely by the experimental method, whereas the fundamental facts were really the outcome of clinical observation.

The greatness of Jackson's conceptions is well seen in the fact that he recognized that cortical localization was concerned with the representation of movements, and not of muscles, and, indeed, with a special kind of movement—namely, voluntary movement. In the earlier days of experimental work on this subject some confusion was introduced by certain observers falling into the error of looking for so-called centres for the representation of muscles; and it was only later that inhibition of antagonistic muscles, as well as contraction of other muscles, was also recognized as a matter of cortical representation. Anyone who has actually seen the movements called forth by the electrical excitation of the cerebral cortex will experience quite different mental impressions from those he will have felt by watching an epileptiform seizure, perhaps confirmed subsequently by seeing the position and nature of the lesion responsible for it. In the one case there is a definiteness and certainty that in the other is apt to be replaced, at the best, by a feeling of high probability. And yet, if we are to succeed in our endeavours to cope with the facts of nature, we must aim at possessing certain, and not probable, knowledge. It may be that this is often, in our work at present, unattainable, but it is the great thing to aim for in all our work. Perhaps some of our mistakes in the practice of our art arise from not clearly differentiating between what we really know and what is only probable; and sometimes, perhaps, we speak with an apparent certainty about matters that are not, in our present state of knowledge, really as certain as we would like them to be. The touchstone of the experimental method of Harvey is a useful corrective whenever and wherever it may be applied to questions of this nature. The modern physiology of the central nervous system, investigated by the experimental method, affords a striking example of the extraordinary precision of knowledge that may be obtained by the use of this method, and, thanks to it, a flood of light has been thrown on the complex problems of the mechanisms involved in posture, equilibration, co-ordination of movement, and perhaps on the still more complex mechanisms associated with the highest functions of the brain. Nevertheless, in an oration associated with the name of Harvey it may perhaps be possible to illustrate the principles of the profound influence exerted by experimental physiology on medicine by seeking an example in that branch of physiology so closely associated with Harvey—namely, the beat of the heart.

I am not so much concerned to-day with giving a record of individually important discoveries that have been made from time to time whereby our knowledge has been increased and our power of recognizing, and treating with some success, individual diseases, has been extended, but rather with the nature of the conceptions we form of the phenomena of heart disease as we see them clinically in the light of the exact modern physiology of the heart, as revealed by the use of the experimental method of Harvey.

The beat of the heart, from the earliest times to the

present, has been looked upon as emblematic of life, by poets, philosophers, and thinkers, and has always had an element of mystery and awe attached to it. No physician will deny that in disease there is much of apparent mystery in what may be called the natural history, or, if you will, the clinical course, of heart disease; further, that the clinical picture presented by individual cases, even where relatively simple lesions are present, is one with much individual variety, that the phenomena are complex and difficult to analyse, and hence there has been much uncertainty of opinion, both in diagnosis and in treatment. Such differences of opinion existed, not only with reference to questions of interpretation or explanation, but even in reference to what we should now regard as mere questions of fact. There must be some present here to-day who will remember a controversy as to the actual time of occurrence of certain well known murmurs associated with a common valvular disease. When the methods available for clinical observation led to such remarkable differences of opinion among physicians of recognized skill and ability, it is not strange that many keen and able minds should have felt that the problems of medicine were so difficult and so complex that it was beyond their power to really solve them with the means at their disposal; and this attitude of mind is one very inimical to the progress of our science and our art. The method of Harvey of seeking the secrets of nature by way of experiment shed a flood of light on the problems that had baffled those who confined their methods to observation. Not only was this the case, but what is of supreme importance to recognize is the fact that many of the men who in recent times remodelled our conception of the nature of cardiac disease by the fundamental character of their discoveries of the nature of the cardiac beat were men who devoted their lives to the investigation of the facts of nature with no other object in view than that of adding to knowledge for its own sake. Great as their discoveries were, they had no idea of their practical bearing on heart disease, and some of them, indeed, were men who had no knowledge of heart disease as such, and never undertook their work with any idea of adding to our knowledge of heart disease. Further, the discoveries of the pure clinicians, remarkable as they were for the acuteness of their observation, were largely due to making use of the methods and apparatus of the laboratory in the investigation of clinical problems. The polygraph and the electro-cardiogram gave certain and accurate information where previously other methods of observation had led only to the dissemination of views, explanations, and theories of varying degrees of probability. It is one thing to be able to actually demonstrate beyond cavil that the auricle of the human heart in a living patient is in the state known to us as that of fibrillation, and another to talk of lack of failure of compensation, with no clear mental picture of the meaning of the words used. Anyone who has seen a fibrillating auricle in the living animal in the laboratory has a mental picture that is not easily forgotten—a picture of a singularly concrete and definite character, with an element of reality about it that cannot fail to be a useful reminder to him when he stands at the bedside of a patient suffering from the effects of this condition. It is, of course, quite true that the acute clinical observers of the past had recognized the clinical picture produced by this condition, and had described quite accurately some of its manifestations. We can but admire their acumen, but they were necessarily unable, owing to the lack of physiological knowledge and the want of accurate methods, to determine the true cause of the symptoms and to correlate the lesion with its results. Hence the inevitable temptation, to some minds, to speculate and theorize vaguely instead of confining themselves to mere observation, and hence the further elaboration of more and more speculation and ultimately much confusion as to what was speculation and what was firmly established by observation. This has often been most harmful to the real progress of medicine, owing to the development of loose methods of reasoning, and the frequent impossibility of bringing the matter in dispute to a decision by the crucial method of experiment.

The history of the development of our knowledge of fibrillation is singularly interesting as affording a striking example of the experimental method having substituted

a clear, definite, and easily proved condition for what was previously a most vague, indefinite, and even intangible conception. But the history of the discovery of fibrillation is even more interesting and important from another point of view, and teaches a lesson of supreme importance to those who are always insistent on investigation being directed to some immediate practical aim. Fibrillation was discovered by a physiologist who was attempting to ascertain where the beat of the heart had its origin; in other words, whether the heart contained a so-called centre from which the beat arose. In the course of his inquiries he found that on stabbing the heart with a fine needle a condition of what we now call "fibrillation" ensued. Sometimes this followed a single puncture, sometimes many were required. Later it was found that faradization of the exposed heart with a current of moderate intensity produced the same result. Sometimes the condition of fibrillation was transitory, in other cases it was permanent; the heart did not recover, and death ensued.

It is unnecessary to-day to go into all the details of the many subsequent investigations on this interesting subject; all that it is necessary to point out here to-day is that this condition of fibrillation was a discovery of experiment produced by such crude and simple methods as repeatedly stabbing or faradizing the exposed heart. I can well remember that it was a common method, some forty years ago, to kill an animal at the end of a physiological experiment by faradizing its heart, and so producing heart delirium or fibrillation. No one who saw fibrillation would have suspected that it was a common condition in human heart disease, and that almost every hospital ward had cases suffering from it, either temporarily or even for long periods of time. It might, indeed, have been argued very plausibly that it was inconceivable that such crude experiments could have any possible use or bearing on vital processes, and still less on human heart disease; and yet we see that the exact opposite is the case, and that, crude as the experiment was and remote as was the connexion between the normal dog's heart and human mitral stenosis, and although the mind of the investigator had no thought of heart disease in his inquiry, nevertheless this crude and apparently idle experiment was of the utmost significance for the intelligent understanding of one of the commonest forms of heart disease.

Another lesson may also be learned from consideration of these results, and that is the reciprocal influence of physiology on pathology, and of pathology on physiology, and how extremely artificial is the boundary between these two departments of knowledge, and how, if we are to have an adequate conception of even relatively simple vital processes, it is necessary to study them with the broadest possible outlook. A pure and rigid physiologist, studying only the normal activity of the heart, would scarcely be prepared to admit that the circulation, in a highly organized mammal, could be maintained when the rhythmical activity of the heart was so disorganized that auricular fibrillation was present. Nevertheless, clinical medicine proves that, even in man, such is the case. Surely such facts as these are of the utmost value, not only in our immediate daily work and in our attempts to treat disease and relieve suffering, but still more so in our appreciation of the nature, the complexity, and, more especially, the adaptability of the activities of living matter. Marvellous as are the various methods by which a circulation sufficient for the needs of the normal animal is effected—and this is well shown by the study of comparative anatomy and comparative physiology—the marvels of the relative efficiency of the disordered circulations of heart diseases are not any less. Certainly the study of these conditions not only widens our conceptions, but is also a useful incentive to our therapeutic efforts when a more limited and narrow belief might lead us to be less hopeful as to the possibility of procuring relief or cure in these conditions.

The history of the study of the phenomena of fibrillation has been cited as an illustration of the very close relationship that exists between experimental science and the daily work of the physician, especially if we wish to found our art on a secure basis of science, and if we desire to eschew empiricism where this is possible. The same illus-

tration may be found equally well in the history of the development of our knowledge as to the nature of the normal beat of the heart and of its disordered action in disease. Here also we see the extraordinarily close connexion between pure physiology on the one hand, and the interpretation of the clinical symptoms of heart disease on the other. It may seem, at first, strange to assert that our present conceptions of the fundamental facts in the pathology of heart disease owe their origin to researches conducted by a physiologist on the nature of the muscular contractions in the umbrella of the jelly-fish, but it is really an unexaggerated and plain statement of fact. Romanes, in the seventies, carried out a series of very beautiful but very simple experiments on the nature of the rhythmical contractions of the umbrella of jelly-fish, being especially interested in the question whether the wave of contraction was transmitted via the nerve plexus—that is, intermingles with the sheet of muscle in these organisms—or whether it was of purely muscular origin. He had but little apparatus beyond a pair of scissors, and, for some purposes, a simple recording lever and a smoked surface. Romanes, in the course of his work, discovered the fundamental fact that what is known as a block was a phenomenon dependent purely upon muscular changes, and due sometimes to a mere narrowing by section of the width of the muscular bridge connecting the two portions of a contracting muscular sheet. In other words, a block might be produced by local alterations in the conducting properties of the muscle itself. Further, he showed that delay in conduction could also be effected by such alterations in the muscular bridge produced by narrowing of the connexion, and that delay in transmission of a muscular wave from one part to another was not in itself any evidence of the intervention of the nervous elements. The importance to us, as physicians, of Romanes's work was that it was the origin of the slightly later and epoch-making work of Gaskell on the nature of cardiac action. We owe to Gaskell a very large part of our modern conceptions of the physiology and pathology of the heart muscle, and the bulk of Gaskell's experimental work, like that of Romanes, is beautiful in its extreme simplicity. Gaskell developed and amplified in the heart of fishes, of amphibia, and of reptiles, and especially in the heart of the tortoise, the fundamental experiments of Romanes; and, like Romanes, some of his most striking results were obtained by the use of experiment, with little more apparatus than a pair of sharp scissors. His fundamental experiment of producing a block by section of the muscle of the auricle, so as to leave only a narrow bridge connecting the sinus portion of the auricle with the ventricular portion, was performed on the heart of a skate on the deck of a yacht whilst cruising off the West Coast of Scotland, not far from where Romanes worked in his seaside laboratory on his jelly-fish.

Gaskell was the protagonist of the doctrine of looking upon the heart as a muscle and of unravelling the properties of cardiac muscle, and of correlating them with those of other muscular tissue, voluntary and involuntary. Further, he correlated structure and function, as shown by the different physiological properties of auricular and ventricular muscle associated with their different structure, and he emphasized, as also did Roy, the great part played by the auricle in the physiology of the heart beat, and its intimate association with the nervous system.

Another of Gaskell's great conceptions was that of the independent rhythm of the separate cavities of the heart and the way in which, under certain abnormal conditions, the prepotency of the sinus end of the heart might be interfered with, and an independent rhythm initiated in some other portion of the heart, as, for example, the ventricles. We owe to him the conception of the heart as consisting of a number of muscular cavities each with an independent rhythm, but the whole dominated by a prepotency at the sinus end. Nevertheless, under certain conditions this might be disturbed by the manifestation of the independent rhythm of some other portion of the heart, more especially the ventricle.

Gaskell's work on the nervous system was of such a striking character, and led to such far-reaching conclusions, that sometimes we are apt to forget that his earlier work on cardiac muscle was certainly of equal importance, and

has had a very great influence on the progress of modern pathological knowledge, especially by clarifying our ideas as to the nature and mode of origin of the cardiac rhythm. We also owe to him and to Roy the conception that the main function of the auricle is to act as a regulator of cardiac activity. As has already been pointed out, all these fundamental facts were discovered by experiment, with very simple apparatus. But in another branch of physiology to which medicine is also greatly indebted the experimental methods necessary in order to elucidate the phenomena were of a more complex character. Forty years ago electro-physiology was looked upon by many as a recondite branch of investigation which might perhaps be of interest, but which could not possibly be of any practical use. Physiologists, like Burdon-Sanderson, were engaged in the investigation of the electrical phenomena associated with the activity of vital processes, simply and solely because it was the most delicate physical method available for the investigation of such phenomena. It is a striking comment on such views as these to reflect that the study of the electro-cardiogram in the human subject and in animals was the actual means by which the condition of fibrillation was verified to exist in the human subject. Furthermore, the electro-cardiogram gives us the most definite and accurate knowledge of the real state of the cardiac muscle, as shown by the nature of its activity.

One of the most striking everyday illustrations of this may perhaps be quoted. Every practitioner is aware that in mitral stenosis under some conditions the presystolic murmur is absent and in others it is present. I know of no more striking demonstration than to be able to show, by means of the electro-cardiogram, that in the one case the auricle is contracting rhythmically, and in the other it is not. The electro-cardiogram removes all doubts and difficulties as to the interpretation of this phenomenon, and gives an element of certainty that is not obtainable by any other method. It has thus led to a precision in the interpretation of some clinical phenomena that leaves little to be desired. On the other hand, it requires an elaborate installation and a considerable amount of technical and special knowledge, and thus is ill adapted for ordinary routine observation.

Although we owe to the electro-cardiogram the complete demonstration of the existence of fibrillation in the human heart, we can recognize the presence of fibrillation by other and simpler methods. It is a common thing in the history of science that the interpretation of facts may require difficult and elaborate experimentation, whilst their recognition can be effected by the use of simpler methods. The electro-cardiogram may be useful for both purposes, but it is perhaps more especially valuable as an instrument of research when attempts are being made to ascertain the fundamental causes of certain clinical phenomena.

Another striking illustration of the profound influence of a simple experimental method of inquiry in advancing our knowledge of the nature of the heart beat, and indirectly of all vital activities, is afforded by Ringer's work on the effect of minute quantities of calcium, potassium, etc., on the heart. His discovery that the activity of a living tissue was dependent upon the presence of calcium was a great discovery, and one the full effects of which are only now beginning to be realized. He, further, had the very remarkable foresight to anticipate, in some respects, the modern doctrine of ions. Ringer's work is perhaps especially noteworthy inasmuch as it was the work of a man trained as a clinical physician, who did not embark on experimental inquiries until he had reached middle life, and then devoted himself to the investigation of what might be regarded as abstract problems of pure physiology. These observations, like those of Gaskell, were what may be called fundamental, inasmuch as they altered our conceptions of the nature of vital processes, in that they replaced what was vague and indefinite by concrete physical and chemical facts. These observers certainly fulfilled Harvey's exhortation to the letter, by searching and studying out the secrets of nature by way of experiment.

I have attempted, in this oration, to show that the pursuit of knowledge by Harvey's experimental method is not to be regarded only as a means for the acquisition of results of great value in our daily work, but also that it

is of supreme importance in laying the foundations of our conceptions as to the nature of the processes we see at work in disease, and that, thanks largely to it, we may claim that medicine has a scientific status as a branch of natural knowledge.

Hence in medicine, as in biology generally, it is true that like causes produce like results, and the successful investigator must realize the profound truth of the lines:

And Nature, the old nurse, took  
The child upon her knee,  
Saying, "Here is a story book  
Thy father has written for thee.

"Come wander with me," she said,  
"Into regions yet untrod,  
And read what is still unread  
In the manuscripts of God."

And whenever the way seemed long,  
Or his heart began to fail,  
She would sing a more wonderful song  
Or tell a more marvellous tale.

### PROCEEDINGS OF SECTIONS AT THE ANNUAL MEETING, NOTTINGHAM, 1926.

#### SECTION OF OBSTETRICS AND GYNAECOLOGY.

COMTNS BERTLEY, M.D., M.CHIR., F.R.C.P., President.

#### DISCUSSION ON CAUSES AND TREATMENT OF UTERINE HAEMORRHAGE WITHOUT GROSS PHYSICAL SIGNS.

##### OPENING PAPERS.

I.—BECKWITH WHITEHOUSE, M.S.LOND., F.R.C.S.,  
Professor of Obstetrics and Gynaecology, University of Birmingham; Honorary Gynaecological Surgeon to the General Hospital; and Surgeon to the Maternity Hospital, Birmingham.

(With Special Plac.)

##### INTRODUCTION.

From the earliest times uterine haemorrhage has been the object of superstition, speculation, and theory. For almost five thousand years its discussion has occupied a prominent place both in medical and lay literature, and it appears perhaps somewhat strange in the twentieth century that so little is really known and accepted about the fundamental facts that control the function of menstruation. To review the past, with the strange myths and beliefs contained in the writings of the Sacred Law, the Ebers papyrus, Pliny, Hippocrates, Aristotle, and the Zend Avesta, is a fascinating study which, although foreign to the present discussion, serves to throw light upon some of the views and customs which even in the world of to-day are by no means obsolete. In modern times, with the sweeping away of superstition and the development of scientific investigation, our difficulties, however, have not lessened. Rather have they assumed a different aspect. During the last century a mass of heterogeneous material has been accumulating, and it is ever more and more difficult to sift the grain from the chaff. Conflicting statements and theories, many based upon insufficient data, have appeared which complicate the points at issue. Within the last few years, however, signs are apparent that at last we are nearing the edge of this morass and approaching more solid ground upon which to build a firmer edifice, based upon the truths of physiological and pathological research.

##### THE MENSTRUAL FUNCTION.

Any discussion upon the causation and treatment of pathological uterine haemorrhage must depend in the first place upon the views that are held with regard to the menstrual function. If we do not know the essential

factors concerned in the production of physiological bleeding, then no great advance may be expected from an incursion into the realms of pathology. A correct conception regarding menstruation is therefore the key which opens the door to a proper understanding of the phenomena associated with pathological haemorrhage. Recent research has done a great deal to dispel the haze which formerly surrounded our knowledge of the function, and during the last few years important advances have been made towards the solution of the complex problems involved in the sexual physiology of the human species. The work of Wilfred Shaw and Marshall and Dixon in this country, Novák, Allen, D'Oisy, and Frank in America, and Schroeder in Germany, is especially noteworthy. The investigations and conclusions of Novák are of special interest to me in that they confirm the views which I published in February, 1914, and which were noted also in that year by Schroeder. I then expressed the opinion that at each menstrual function there was a definite shedding of a portion or portions of the superficial endometrium, and that the menstrual discharge consists of the autolysed products of the result of this necrosis. I believed then, as I believe now, that the secretion of the glands of the uterine body is concerned in the breaking down of the menstrual clot composed of blood coagulum and tissue debris. W. Shaw has also demonstrated this clot in the uterine cavity of a young healthy woman killed by trauma upon the first day of menstruation, and I am able to-day to submit another specimen in the case of a uterus removed on the first day of the menses from a patient suffering from menstrual epilepsy (Figs. 1, 2, and 3), and the only modification which I think desirable in the light of recent work is that in most cases autolysis of the clot and tissue commences whilst the separating endometrium is actually in anatomic contact with the deeper layers, and whilst the extravasated blood is intimately associated with the epithelial debris.

That thrombolysis is generally by no means complete is evident to anyone who cares to examine daily the discharge from a series of cases of normal menstruation. It is not sufficient to accept the word of a patient that clots are not present in the discharge. Minute coagula in process of solution are not recognized as "clots" by the lay mind, and they can only be detected if a systematic search is made for them. For several months I have had the menstrual discharge investigated of patients not suffering from pelvic disease, admitted to the medical wards of the General Hospital, Birmingham, and I have been surprised at the frequency with which small coagula are present. It is the exception rather than the rule for no clots to be passed at some time during the menstrual function. When the menstrual discharge is centrifuged and the deposit examined microscopically, epithelial debris of endometrial origin can often be detected (Fig. 5). If the specimen is collected on the third or fourth day of the function, it is more difficult to demonstrate actual tissue, but a careful search will usually reveal "ghosts" of both uterine glands and stroma cells. Novák has described the actual desquamation of the mucosa as a "crumbling molecular process, small strips and bits of granular degenerated mucosa being cast off until only the 'basalis' and perhaps a few 'spongiosal' rests are left." This, I believe, accurately and definitely describes what takes place and is entirely in accordance with my own views.

What, then, is menstruation? In the light of recent researches upon ovulation and the development of the corpus luteum I think that we must regard it as an afertile abortion of the non-pregnant decidua. This is no new conception. It was combated by Teasler and others on work based upon the study of early ova. Most of their arguments, however, fall to the ground in the presence of the facts now available with reference to the life-history of the corpus luteum and the coexisting condition of the endometrium. Menstruation apparently follows death of the unfertilized ovum, and is synchronous with commencing retrogression of the corpus luteum. Rupture of the ovarian follicle with escape of the ovum and growth of the corpus luteum initiates development of the pre-menstrual hypertrophy of the endometrium, which correctly should be called the "menstrual decidua."

Once the ovum is discharged from the follicle it is probable that the duration of its life is a definite factor. To survive it must meet with the spermatozoon. If it is not fertilized it dies, and the result is retrogression of the corpus luteum and necrosis of the menstrual decidua; the products of decidual necrosis are then cast off as the menstrual discharge, for which I suggest the more appropriate name of "menstrual lochia." The possible inhibiting effect of the corpus luteum upon rupture of succeeding follicles is removed by menstruation, and the cycle is once more resumed. The old theory that the menstrual function is necessary for the reception of the ovum is, I am quite convinced, a pure myth. Its onset at puberty merely emphasizes the fact that ovulation has taken place before the opportunity for fertilization has occurred. In races such as certain tribes of Indians it is, indeed, difficult to arrive at the age of puberty, because marriage is consummated and pregnancy often occurs before any menstrual lochia has appeared. The explanation is the same, of course, in cases of fertility during lactation, after the so-called menopause, and during pathological states of amenorrhoea. Should an ovum mature long after its fellows, it will and must produce either an afertile abortion, noted clinically as a functional haemorrhage after the menopause, or else a post-menopausal pregnancy, if it has had the fortune to meet with a spermatozoon.

The analogy existing between the menstrual abortion and an abortion during the early months of pregnancy is very striking when the two processes are compared. In each there is softening and dilatation of the cervix; in each uterine contractions are present, and in each there is subsequent expulsion of necrosed decidua. Investigation of the discharge on the second or third day after an early complete abortion shows that it has much in common with the menstrual lochia. Menstruation is, in fact, nothing more than the disorderly action of a disappointed uterus; or, perhaps, shall we say a disappointed ovum.

#### PERIODICITY OF THE MENSTRUAL FUNCTION.

To understand the remarkable periodicity of the menstrual function in the human species we must remember that in the genus *Homo* we are concerned with the most highly specialized organism as yet evolved. Woman has developed from her ancestors much as the domestic hen has evolved from the Indian jungle fowl. Just as breeding, environment, and feeding have been utilized by man to alter the sexual rhythm of the jungle fowl and the Indian runner duck for his own advantage, so evolution has altered the sexual rhythm in woman from that of her predecessors. In fact, intensive egg-laying production in the domestic fowl is a commercial scientific experiment upon artificial variation in sexual rhythm. It is the ovarian follicles to which we must look, both for the cause of the regular monthly abortion and for the irregularity so commonly associated with the beginning and end of sexual life. Factors which interfere adversely with the maturation and discharge of the ovum are reflected upon the rhythm of the menstrual function. Halban, by excising the corpus luteum in 40 cases, was able to induce menstruation. In 92.5 per cent. uterine haemorrhage occurred in from two to four days after operation. I have recently confirmed these findings of Halban in an experiment to which I shall subsequently refer.

There has been in the past, and there still exists, a tendency to compare the menstrual function in the human species with the phenomenon known as pro-oestrus in the mammalia. It is not necessary here to go into the matter at length, as it has been so fully considered by Hearn and also by Novák. The arguments both for and against are probably known to most of us. The only observation it is necessary to make is that in the case of *Homo* we are dealing with a very highly specialized organism. In the lower animals also investigation has been mainly confined to the domestic types, which are artificial products, and in which the normal mon-oestrus or di-oestrus cycle has been converted into the poly-oestrus habit.

This artificial development of the poly-oestrus type is, I think, a most interesting and important aspect of comparative physiology to the gynaecologist, and one which deserves close investigation.

## BECKWITH WHITEHOUSE: CAUSES AND TREATMENT OF UTERINE HAEMORRHAGE.

FIG. 1.—Transverse section through the cavity of the normal healthy uterus on the first day of menstruation. The menstrual decidua is well shown. Note the dilatation of the uterine glands in the "spongiosa layer" produced by constriction of the ducts in the "compact" layer. The uterine cavity is occupied by the menstrual clot consisting of menstrual decidua and fibrin.

FIG. 2.—The menstrual clot occupying the uterine cavity on the first day of menstruation. Note the compression of the ducts of the uterine glands in the adjacent decidua which is not necrosed. The sudden escape of the uterine secretion has in other glands produced separation of the gland epithelium from the basement membrane. (Magnification 24; 2 in. obj.)

FIG. 3.—The menstrual clot on the first day of menstruation, showing part of a necrosed uterine gland and decidual detritus. (Magnification 120; 1/3 in. obj.)

FIG. 4.—The menstrual decidua on the first day of menstruation, showing necrosis of the stratum compactum. A partially broken down gland duct is well shown. Note the separation of the epithelium from the basement membrane, which follows sudden escape of the pent-up secretion.

FIG. 5.—The menstrual abortion. Tissues obtained by centrifugalization of the menstrual lochia from the vagina. The material was obtained from the vagina fifty-five hours after excision of the corpus luteum. Note the necrosed uterine glands. Decidual cells are seen in close proximity to the gland epithelium. (Magnification 220, 1/6 in. obj.)

FIG. 6.—The menstrual clot, collected from the uterine cavity fifty-five hours after excision of the corpus luteum. Both uterine glands and stroma cells are present. The glands are active, but have not been dilated because at this stage there is no marked development of the decidua compacta.

BECKWITH WHITEHOUSE: CAUSES AND TREATMENT OF UTERINE HAEMORRHAGE.

FIG. 7.

FIG. 8.

FIG. 9.

DESCRIPTION OF FIGS. 7, 8, AND 9.

FIG. 7.—Another section of the intrauterine clot obtained after removal of the corpus luteum and showing both gland and stroma tissue. A few developing decidual cells are shown on the right of the section. (Magnification 280;  $1/6$  in. obj.)

FIG. 8.—Curetting from the anterior wall of the uterus, fifty-five hours after excision of the corpus luteum and sixteen hours after the clinical onset of the artificially produced menstrual abortion. Note the necrosing endometrium, especially in the superficial layers. There is no great dilatation of the uterine glands because the stratum compactum of the decidua is not fully developed, and there is but little constriction of the ducts.

FIG. 9.—Curetting from the anterior wall of the uterus fifty-five hours after excision of the corpus luteum, showing necrosis of the superficial layer of the endometrium. (Magnification 150;  $1/3$  in. obj.)

R. MCCARRISON: A GOOD DIET AND A BAD ONE.

FIG. 1.—Medium sized rat from the colony fed for six months on the "good diet."

FIG. 2.—Medium sized rat from the colony fed for six months on the "bad diet." (Same scale as Fig. 1.)

FIG. 3.—Photomicrograph of part of a villiform papillomatous outgrowth in proximal portion of the stomach of a rat fed on the "good diet" referred to in the text. ( $\times 400$ .)

FIG. 4.—Photomicrograph of part of a villiform papillomatous outgrowth found in proximal portion of the stomach of a rat fed on the "bad diet" referred to in the text. ( $\times 400$ .)

In the human species confusion has arisen partly owing to the fact that possible fertilization is permitted at any time following the pro-oestral abortion. In other words, the oestral period is prolonged up to and including the next pre-gravid state of the endometrium. This variation of the sex instinct is important, and must not influence the consideration of, and comparison with, the sexual rhythm of lower types. The sexual instinct in *Homo* is independent of the uterus and ovaries, as is shown by its development before puberty and its persistence after the natural or artificial menopause.

Finally, the association of the ovary with the accessory genital glands, notably the thyroid and pituitary, appears to be of increasing importance. Although woman is primarily built around her ovaries, there is abundant and accumulating evidence to prove that these organs are but a single link in the mechanism responsible for the metabolic rhythm of the adult female from puberty to the menopause. It is, I think, probable that the thyroid initiates the maturation and rupture of the first ovarian follicle, and is therefore responsible for the first menstruation. Previously, as pointed out by Wilfred Shaw, follicles become atretic and are converted into corpora testiformia. With the rupture of the first follicle and development of the first corpus luteum the sex cycle is instituted. This cycle is intimately associated with variations in the basal metabolic rate. It is too early to draw reliable inferences from the data as yet available, although Wakeman's observations on the pre-menstrual rise in basal metabolism and the subsequent fall during or immediately after the function may point to a periodic thyroid activity. The researches of Heilig upon the sugar tolerance during menstruation, and of Bond upon the raised ammonia coefficient during the pre-menstrual phase, all point to the extreme complexity of the sexual cycle, and to the truth of Blair Bell's modification of van Helmont's dictum—namely, "propter secreciones internas totas, mulier est quod est."

#### THE UTERINE SECRETION.

Very little appears to be known, or at least published, with regard to the function of the glands of the corporeal endometrium. Schroeder has pointed out that the first signs of secreting activity appear in the uterine glands about the fourteenth or sixteenth day of the menstrual cycle; in other words, about the same time as the corpus luteum is approaching maturity.

In a series of experimental investigations upon rabbits I found in these animals that if the ovaries were present the secretion of the uterine glands, when injected into other animals, produced the signs of pro-oestrus. On the other hand, if the animal had been previously oophorectomized, the uterine secretion was inert, as well as being less in amount. It appears possible, therefore, that in some animals at least the uterine secretion is reabsorbed and is a factor in the production of oestrus. In the human species, although absorption from the vagina is possible, it is unlikely that the uterine secretion has any great part in the production of the sex instinct. It may be a stimulus, but it is not the only factor, since this instinct persists after the menopause, and even after removal of both the uterus and ovaries. It is possible, however, that the uterine secretion is responsible for the pelvic hyperaemia associated with menstrual abortion, and in fact with early pregnancy. When fertilization does not occur I also think that the uterine secretion is responsible for removing by autolysis the necrosed menstrual decidua and coagula. Uterine secretion can and does occur without menstruation, but is always associated with it. It appears more than probable that some of the confusion that exists in the conception as to what menstruation really is, is caused by the fact that two separate functions are concerned—the second in a sense complementary to the first:

- (a) The menstrual haemorrhage is an abortion, caused by death of the unfertilized ovum, and retrogression of the corpus luteum resulting in necrosis of the menstrual decidua.
- (b) The menstrual secretion from the uterine glands is an accessory factor, possibly stimulated by the liquor folliculi liberated from the ovarian follicle and absorbed

by the peritoneum. Its primary object in the lower animals appears to be to stimulate oestrus. In the human species it appears also to have an action upon the products of the menstrual abortion.

#### The Artificial Production of Menstrual Haemorrhage.

I propose to give details of an investigation recently conducted to prove the truth of Halban's assertions, and to ascertain the possibility of the artificial production of a menstrual abortion. On June 8th, 1926, during the course of an exploratory laparotomy performed at the request of a medical colleague, the opportunity occurred of excising the corpus luteum in a perfectly healthy young woman. The operation was timed to take place about the mid point of the menstrual cycle—namely, the sixteenth day.

The patient, M. L., aged 23, a 1-para, was admitted to the General Hospital, Birmingham, on June 6th, 1926. A careful menstrual history showed that the last period began on May 23rd and lasted until May 26th. The rhythm was of the normal twenty-eight day type, and the patient volunteered the fact that "she was never a day out." In fact, she had always been perfectly regular from the onset at the age of 14, except during her one pregnancy.

Laparotomy was performed at 10 a.m. on the morning of June 8th. The pelvic organs exhibited no signs of disease. Examination of the ovaries showed a well developed corpus luteum in the right organ. A few follicles were nearing the surface, and one appeared nearing the point of rupture. The left ovary presented a small corpus luteum in process of retrogression, the yellow colour being plainly visible; also a large, apparently mature, follicle was seen on the surface of the left ovary. The only trauma effected was excision of the large corpus luteum from the right ovary. Great care was taken during the operation not to puncture or excise a single follicle, so that the subsequent observations could not be influenced by the question of absorption of the liquor folliculi.

On the morning of June 9th, twenty-four hours after operation, the patient complained of backache, and said she "felt as though a period was coming on." At 1.30 on the morning of June 10th, thirty-nine hours after excision of the corpus luteum, and on the eighteenth day of her menstrual cycle, uterine haemorrhage commenced. At 9.30 the same morning the "period" was well established. At 5 p.m. on the same day—that is, sixteen hours after the clinical onset of the haemorrhage and fifty-five hours after excision of the corpus luteum—the patient was again taken to the theatre and the uterus curetted.

A sample of the discharge in the vagina was first collected and examined by Dr. Hillier. No clot was present in the sample, which appeared to consist of a mixture of blood and the mucous secretion of the cervical glands. The fluid was dark in colour, and had the typical appearance and consistency of menstrual blood. Marked activity of the cervical glands was present, and the cervical canal was partly dilated.

A glass tube was easily passed into the uterine cavity through the dilated canal, and a specimen of the contents of the uterine body was collected. This also showed the usual appearance of the contents of the uterus on the first day of menstruation, and consisted of breaking down clot and tissue detritus. The material was fixed and sectioned.

The uterus was then carefully curetted, the tissue from the anterior and posterior walls and fundus being fixed and sectioned separately.

The material obtained from this investigation will form the subject of a paper to be published in the *Journal of Obstetrics and Gynaecology of the British Empire*.

I take this opportunity of stating, however, that the endometrium presents the appearance of what I regard as being an abortion of the partially developed aconceptional pre-gravid decidua (Figs. 5, 6, 7, 8, and 9). The investigation, whilst confirming Halban's observations, has thrown light upon the cause of certain functional uterine haemorrhages, and shows the importance of the correlation between the corpus luteum and the endometrium.

#### FUNCTIONAL PATHOLOGICAL UTERINE HAEMORRHAGE.

The following remarks are based upon data obtained by the study and analysis of 200 consecutive cases of functional uterine haemorrhage, with no obvious physical signs, admitted to the gynaecological department of the General Hospital, Birmingham. The pathological work has been carried out with the help of Professor Haswell Wilson and Dr. Hillier, to whom I am much indebted for the care and time spent in the preparation of the sections and reports.

Pathological uterine haemorrhage falls naturally into one of four groups. Either the periods are too frequent, or they are too prolonged, or they are too severe as measured by the blood lost, or the bleeding is quite irregular. For

some years past I have grouped cases of haemorrhage on this basis, and I think that the classification has been of use both from the clinical and the pathological aspects. As knowledge has increased I have found the grouping still more valuable, as the terms "epimenorrhoea" (Blair Bell), "menostaxis," "menorrhagia," and "metrostaxis" respectively convey a definite pathological entity. With the conception of menstruation as being an unfertile abortion, I propose to consider pathological haemorrhage under these four headings.

#### *Epimenorrhoea (Blair Bell).*

Epimenorrhoea, or too frequent periods, is the clinical manifestation of a hyperactive state of the sex complex. It means that the ovaries are working at too high pressure and probably producing ova of low vitality, with the natural result of frequent abortion. Such ovaries as I have had the opportunity of investigating in this condition are hyperplastic and often polycystic. Corpora albicantia, as distinct from corpora atretica, are frequent, and the ovaries usually contain much retrogressive luteum tissue. The endometrium, when epimenorrhoea has been in existence for some time, becomes hyperplastic, but in the early stages shows very little that is abnormal if viewed in conjunction with the altered menstrual rhythm and the state of development of the most recent corpus luteum. At the commencement and end of sexual life epimenorrhoea is common and may almost be regarded as physiological. Curettage for such a condition is of course useless. It merely serves to remove more thoroughly the products of the most recent menstrual abortion, but it does not influence the underlying cause—namely, the disordered sex rhythm and too frequent ovulation. Since the sex rhythm is not governed by the ovaries, but by the "sex complex," it is probable that therapy directed towards inhibition of the accessory sexual glands, especially the thyroid, will be attended by more success. Aleck Bourne has already shown the good results of treatment by the application of x rays to the thyroid in the irregular haemorrhages of puberty. I have recently similarly treated thirty cases of menopausal haemorrhage of the epimenorrhoea type, with very satisfactory results. A line of investigation upon which I am also at present engaged is the possible production of follicular inhibition by the injection of fresh corpus luteum extracts.

#### *Menostaxis (Whitehouse).*

Menostaxis, or a prolonged "period," is, I believe, analogous to an incomplete fertile uterine abortion. The menstrual lochia is normal in composition, but instead of ceasing in the usual four or five days continues for twelve days or longer. No clots as a rule are passed per vaginam. Occasionally a few small coagula in process of thrombolysis are found in the vaginal discharge. The endometrium presents an appearance which for a long time puzzled me, and to which I have previously drawn attention. If several preparations of the curettings are made from different parts of the uterus an entirely different picture is shown. One section shows the normal post-menstrual phase, another is in an active state of superficial necrosis, and another may show well marked pre-menstrual decidua. Whether this incomplete abortion is associated with slow or atypical retrogression of the corpus luteum I do not yet know, as I have not had the opportunity of investigating the ovaries in such cases. The symptoms do not occur with every period, but often there is a history of several prolonged periods in the same patient. Chronic inflammation of the endometrium predisposes to its occurrence, as "plasma" cells are frequently seen in the stroma. I am quite sure, however, that inflammation or true endometritis is not the only cause, as it definitely occurs with an apparently healthy endometrium. I strongly suspect that the corpus luteum is intimately associated with this type of haemorrhage, although it must be noted that a simple curettage frequently cures the condition.

#### *Menorrhagia.*

In the very limited sense in which I employ the term—namely, as a severe menstrual haemorrhage practically amounting to the popular word "flooding," but not over-

stepping the usual bounds of the "period" with regard to the limits of duration or time—menorrhagia has a very different pathology. It is, I think, comparable to the inertio type of post-partum haemorrhage, and is essentially due to what may be termed "uterine insufficiency." The endometrium, in cases of true menorrhagia, often shows very little that is abnormal if curettage is performed some days after the bleeding has ceased. If the curettings are obtained while the haemorrhage is still in progress—and I believe that this is the time when the operation can be most usefully performed—the tissue shows large "lakes" produced by extensive subepithelial haematomata. If the haemorrhage has been in progress for some time there is a corresponding extensive necrosis of the superficial decidua compacta. Regeneration is very rapid from the decidua spongiosa, and soon after the period the endometrium again presents the normal appearance. Curettage at this time fails to show any pathological lesion.

Uterine insufficiency may be the result of many diverse factors affecting both metrium and endometrium. It is associated with chronic subinvolution and the changes in the uterine wall related to chronic metritis as described by Professor Fletcher Shaw. It is also on occasion a temporary developmental attribute of adolescence. Senility is frequently associated with uterine insufficiency owing to atrophy and fibrosis of the uterine wall. I have also investigated cases of true menorrhagia where the underlying cause appeared to be general debility, asthenia, or anaemia. In fact, any condition, general or local, which interferes with normal uterine contraction and leads to stagnation of the uterine circulation will predispose to the true menorrhagic type of haemorrhage.

Menorrhagia is infinitely more serious than menostaxis, and if the cause is not removed a severe degree of secondary anaemia is soon produced. The haemorrhage is always severe, and usually differs from the preceding group in that it is associated with the passage of large clots. In milder degrees it appears eventually to produce hyperplasia of the endometrium. Curettage temporarily relieves the haemorrhage, and this may be sufficient in the case of the menorrhagia of puberty. In other cases it is best to combine it with radiation of the thyroid, as previously noted. In the menorrhagia of the menopause, the intrauterine application of radium is the most useful therapeutic measure available, in that it destroys the tissue which aborts.

#### *Metrostaxis.*

This term is, I think, preferable to the older "metrorrhagia"; it includes all haemorrhages independent of the menstrual cycle. It must not be confused with irregularity of the menstrual abortion. Clinically the distinction may be made by investigation of the uterine discharge. In the case of irregularity of the menses the discharge has the typical characters of the menstrual lochia, which are now well known. In true metrostaxis the haemorrhage is frequently severe. It is bright red, and large clots are not infrequently present. Patients commonly note the distinction themselves when giving an account of their symptoms.

In my experience the most commonly noted pathological condition of the endometrium associated with metrostaxis is hyperplasia. Whether this is compensatory, or the result of chronic congestion of the endometrium, associated with pathological changes in the ovarian follicles or corpus luteum, remains still to be proved. The hypertrophy is usually diffuse, but may be localized as in the case of the simple adenomatous polypus of the endometrium. That a small single polypus may sometimes be the only recognized lesion associated with severe metrostaxis is strange; and appears to point to the existence of some deeper underlying and unknown cause. A polypus, in fact, may be but a local safety-valve, or an isolated point where tissue resistance of the endometrium to the underlying forces has broken down.

The problem of metrostaxis will not, I think, be completely understood until we know more about the innervation of the uterus, and the functions of the autonomic nervous system in so far as it controls the internal genital organs. That the uterine, and probably ovarian, functions are influenced by the nervous mechanism, either directly or indirectly through the thyroid, is shown by

many clinical instances. The onset of labour or the occurrence of abortion, whether it be fertile or unfertile (menstruation), as the result of mental shock may be cited. The following case illustrates this type of "uterine bleeding."

Mrs. J., aged 33, met with a motor accident whilst being driven by her husband. She was thrown out of the car, but was not injured beyond receiving a few contusions. Her husband, however, sustained a fractured limb and his wife assisted in conveying him home. Her menstrual period was "due" the day after the accident, but did not commence until three days later. It was then very severe and continued for a week. Two weeks later haemorrhage recurred and continued at irregular intervals for two months. The loss was bright red and was not controlled by rest or by any of the usual medicinal agents employed to check uterine bleeding.

On examination, the patient showed no thyroid enlargement. She was, however, somewhat nervous and excitable, and her basal metabolic ratio as estimated by Reid's formula was + 36 per cent. The pelvic organs presented no abnormality as regards ordinary physical signs.

The uterus was not curetted and the patient was treated by the application of x rays to her thyroid. After the second application the haemorrhage ceased and the normal regularity of her periods was resumed. A recent inquiry has shown that the patient, after some months, is still quite regular, and the bleeding is not excessive.

It is difficult in a case like this to say whether the uterine haemorrhage and the hyperthyroidism were both due to the mental shock, or whether the menstrual abortion was the result of the thyroid activity secondary to the nervous stimulus.

Metrostaxis is in many respects comparable to gastrostaxis, which, as Hale-White pointed out, is practically confined to the female sex, and independent of any relation to the menstrual rhythm. The sympathetic vasomotor centres in the tractus intermedio-lateralis of the medulla demonstrated by Müller are probably intimately associated with these functional haemorrhages. The recent work of Mariano Castex has shown that these centres are also vasotrophic. Observations such as these point to the wide field of research that is as yet unexplored in its relation to the genital tract. It is not surprising that the endometrium should be particularly susceptible to outside influences when the embryonic nature of its structure is taken into consideration. It is constantly in a state of necrosis and repair, and in this respect differs from any other tissue in the body. Furthermore, I think that perhaps in the past we, as gynaecologists, have been a little short-sighted and narrow in our observations. We have been too inclined to look for and expect a local change in the endometrium, and to label any abnormal appearance—for example, hyperplasia—as being the possible cause, rather than the result, of continued bleeding. We must remember that the uterus and ovaries are but two links in the sexual chain, which are subservient to, and are probably governed by, the metabolic and nervous activities of the individual. It is for this reason that I have avoided detailed reference to endometrial changes—whether the change be hypertrophy or atrophy—in my remarks upon metrostatic haemorrhage. The uterus, as Cullen wittily remarked, is "an organ upon which many tunes are played." Let us, therefore, in our discussion think not only of the instrument, whether it be good or bad, but direct our attention also to the technique of the artist, and remember that a woman may possibly blush with her uterus as well as with her skin! The conclusions, therefore, which I have reached and which I now submit for discussion, may be summarized as follows:

1. Menstruation is the monthly abortion of the decidua of an unfertilized ovum.
2. The menstrual discharge is the lochia of an unfertile abortion.
3. The pre-menstrual endometrium is the menstrual decidua, and its development and life are dependent upon the corpus luteum.
4. Menstrual abortion is initiated by death of the unfertilized ovum and retrogression of the corpus luteum.
5. Pathological uterine haemorrhage falls into one of four clinical groups: (a) epimenorrhoea, (b) menostaxis, (c) menorrhagia, (d) metrostaxis.
6. Epimenorrhoea is the clinical manifestation of 'hyper-activity of the sex complex.'
7. Menostaxis is an incomplete unfertile menstrual abortion.

8. Menorrhagia is the result of uterine insufficiency, which may be (a) developmental, (b) inflammatory, or (c) degenerative. The insufficiency may be associated with lesions in (1) the metrium, or (2) the endometrium.

9. Metrostaxis is commonly the reflection of outside influences upon the uterus. The accessory factors most commonly associated with irregular uterine bleeding are (1) functional hyperthyroidism, and (2) hypersensibility of the sympathetic nervous system.

10. Estimation of the blood tolerance of sugar and of the basal metabolic rate provides important data in the investigation of uterine haemorrhage at periods of unstable equilibrium, especially puberty and the menopause.

#### II.—WILLIAM FLETCHER SHAW, M.D., CH.B.,

Professor of Obstetrics and Gynaecology, Victoria University of Manchester.

UNTIL recent years the cause of uterine haemorrhage had been sought in some pathological change of the uterine wall or endometrium, but Professor Beckwith Whitehouse has made us take a much wider view, and to-day, in making such an investigation, we have to bear in mind disorders of the endocrine glands, disordered physiological action of the uterus and endometrium, as well as pathological changes in these tissues. Of all these causes, changes in the endometrium present the greatest difficulty, and many conditions which were formerly considered to be due to pathological changes are merely part of the physiological monthly cycle, while others may be merely the manifestation of disordered physiological processes outside the endometrium.

The endometrium is one of the most interesting tissues in the body, and there are still many changes found in it which require explanation. Why, for instance, do we so frequently find mucous polypi as a cause of haemorrhage after the menopause? The endometrium is now atrophic, and should not undergo local hypertrophy, but it very frequently does so.

Professor Beckwith Whitehouse has dealt particularly with haemorrhage due to disordered physiological processes in the uterus and endocrine glands, so my remarks to-day will be confined to the histological changes found in the uterine wall in three pathological conditions in which haemorrhage is the chief symptom. This type of uterus has interested the gynaecological profession for a very long period, and there is now a large literature on the subject. Unfortunately the earlier workers have each published their views without reference to the work of other investigators, and in many instances have coined titles founded on clinical symptoms or faulty pathology. This has caused great confusion of thought, as we find the same type of uterus described under so many different names, such as chronic metritis, fibrosis, climacteric haemorrhages, arterio-sclerosis, haemorrhagica myopatica, chronic areolar hyperplasia, etc. If these papers are carefully read it will be found that the authors are really describing the same type of case, and the time has now arrived when our knowledge is sufficiently well established to discard these old titles and group these

uteri under the three headings descriptive of the conditions which produce these changes: chronic metritis, subinvolution, and hypertrophy. All these conditions produce a uterus which is regular in shape, somewhat enlarged, rather denser than normal, and all are accompanied by increased haemorrhage. The clinical history alone is usually sufficient to determine into which class the uterus falls, whilst histological examination definitely settles the point, as the microscopical appearance in each group is quite characteristic, though the first two, chronic metritis and subinvolution, frequently appear in the same uterus, though in varying degrees. If all teachers will accept this classification the task for our students will be much simplified.

In the normal uterus there is always maintained a definite balance between the musculature and the flow of blood through the vessels, and this flow can be regulated by contraction of the muscle fibres. Anything which upsets this balance produces haemorrhage, and so we find this symptom well marked in all cases where the flow of blood is excessive, as in an inflammatory lesion, and also in those uteri in which some pathological change has damaged the musculature or placed a pad of inert tissue between the musculature and the vessel walls. There are two pathological changes which are specially liable to upset this balance—chronic metritis and subinvolution.

#### *Chronic Metritis.*

Chronic metritis, used in its true pathological sense, is always the result of inflammation. In the majority of instances the inflammation has occurred during the puerperium, though in a small percentage of cases the change is found in uteri which never have been pregnant but have been subjected to acute inflammation from some infection such as gonorrhoea. When the uterus is inflamed, much of its muscular tissue is destroyed and replaced by inflammatory exudation. In the process of repair this inflammatory exudation is converted into fibrous tissue, and so we find in such a uterus a diminished amount of muscular and an increased quantity of fibrous tissue. In the normal uterus the vessels are seen to be surrounded by muscle bundles with a very small quantity of interspersed fibrous tissue, whereas in chronic metritis the vessels are surrounded by large masses of fibrous tissue with only a small quantity of normal muscle fibres. In such a uterus not only is the muscular tissue diminished, but it has to act on the vessels through a mass of inert fibrous tissue placed between it and the vessels; hence excessive haemorrhage is produced. This is the condition which quite correctly can be called "fibrosis," but unfortunately this term has not been limited to the uterus showing this change, but has been applied to the more common condition of subinvolution where the chief changes are of an entirely different character, though there is usually some chronic metritis accompanying this change. It will be better, therefore, to discard this term entirely and substitute "chronic metritis."

This condition without any accompanying subinvolution is rare, but it does occur, and so the title must be retained in our classification.

#### *Subinvolution.*

Involution is one of the most interesting processes which occur in the body. A nulliparous uterus consists chiefly of muscular tissue plentifully supplied with blood vessels and with only a small amount of fibrous and elastic tissue. The fibrous tissue is interspersed between the muscle bundles, but the elastic tissue is chiefly confined to the inner coats of the blood vessels. During pregnancy all these tissues increase in amount, especially the blood vessels which have to convey the increased quantity of blood necessary for the enlarged uterus and for the growing ovum.

In the course of a few weeks a uterus which weighed 2 lb. at the end of labour diminishes in size to that of a normal uterus weighing about 2 ounces. As the main bulk of the uterus consists of muscular tissue the diminution in size chiefly takes place in this tissue. The individual muscle fibres diminish in size and many completely disappear. This is brought about by a change in the muscle which allows the superabundant tissue to be absorbed. Concurrently with the diminution of the muscular tissue

there is diminution of elastic and fibrous tissue and in the size of the blood vessels, but in these tissues this diminution is brought about by a different process, our knowledge of which we owe to the researches of Goodall. The fibrous and the elastic tissues early in the puerperium undergo what he calls "vitreous degeneration." These tissues swell, soften, and lose their physiological properties and their staining reaction. Elastic tissue which is normally stained blue-black with Weigert's stain at first becomes brick-red and later will only take a pale yellow stain. This state is necessary for involution, as it is only in this condition that these tissues can be absorbed, and if involution proceeds normally the extra bulk of these tissues disappears concurrently with that of the muscular tissue. During this stage the blood vessels, especially those supplying the placental site, also diminish in size as they now have to carry a very much smaller volume of blood. They do this, not by means of a simple contraction as one might expect, but by the formation of new vessels within the old ones. Goodall has shown that the first change in these vessels is thrombosis. In some of them the thrombosis is complete and these vessels eventually disappear. In others one, two, three, or more channels are left in the thrombus through which a diminished quantity of blood can circulate. Very soon these channels receive an endothelial lining and then are surrounded with a layer of elastic and muscular tissue derived from the old vessel walls, and in a little time we have one or more complete new vessels formed within the lumen of the old vessels, and at this stage we can see these new vessels surrounded by the old vessel wall. As involution proceeds the whole of this old vessel wall should be absorbed, and at the end of the process there should be merely this group of one or more new vessels with no trace of the old walls surrounding them, but I have never yet examined any parous uterus in which some traces of the old vessel wall could not be found surrounding the new group. At the end of the involution period the elastic and fibrous tissues undergo what Goodall calls "vitreous hypertrophy." The remains of these tissues all through the uterine wall retain their present bulk but regain their old physiological and staining properties.

If involution is complete, sections through the uterine wall will now be exactly the same as in the nulliparous state, but if involution has not been quite perfect there will be some remains of the old vessel walls surrounding the new ones. The muscular tissue of the old vessel becomes merely part of the muscular tissue of the uterine wall, but the elastic and fibrous tissue will remain unabsorbed outside these vessels, and any uterus which shows patches of elastic tissue outside the vessel walls must have been pregnant, as there is no other condition which allows of the development of elastic tissue in this situation. No matter how normal the involution may appear to have been, it is never quite complete, and I have never examined any parous uterus in which small amounts of elastic tissue could not be found outside some group of vessels. This tissue is in such small amount that it produces no physical signs, but its presence is a definite proof that the uterus has at some previous time been pregnant.

In subinvolution the whole process of involution is incomplete. The uterus remains large and bulky, because the muscular tissue has not been absorbed, and, in addition, there is an increased quantity of fibrous and elastic tissue, especially the latter; it is the collection of this tissue in large quantities around the blood vessels which gives the characteristic microscopical appearance in subinvolution and which accounts for the chief symptom of haemorrhage, as it is impossible for the muscular tissue of the uterus satisfactorily to control the flow through these new vessels if a fixed inert mass of elastic tissue is placed between the muscle and the vessel walls, and so these cases usually give a history of excessive haemorrhage dating from a confinement. In some of these uteri menstruation is normal after involution, but as the patient approaches the menopause the symptom of excessive haemorrhage appears. These are cases in which involution has proceeded to a medium degree and the excessive amount of muscular tissue is able to control the blood vessels, even though a considerable amount of elastic tissue is placed between them; but as the patient approaches the menopause and the muscle undergoes normal

atrophy, even though the flow of blood through these vessels is diminished, the balance between the two is lost, and so we find these patients complain of increased haemorrhage as they reach this physiological period.

Subinvolution and chronic metritis frequently occur in the same uterus, the inflammation which caused the replacement of muscular tissue by fibrous tissue being the cause of subinvolution, which, in its turn, prevented the absorption of the elastic tissue. In these cases there is a marked increase in the percentage of fibrous tissue. Subinvolution is the cause of haemorrhage in the majority of parous uteri which show no signs of fibromyomata or malignant growths.

#### *Hypertrophy.*

Occasionally we find a uterus regular in outline, somewhat enlarged, which produces haemorrhage in a nulliparous woman. In these uteri the endometrium is always much thickened, and I have always looked upon this change in the endometrium as the cause of the haemorrhage, though the thickening of this tissue and the haemorrhage may alike be the manifestation of disordered physiological processes outside the uterus. The uterine walls in these cases are greatly thickened, but there is no alteration in the distribution or amount of the muscular, elastic, or fibrous tissue, and a section taken from such a uterus is indistinguishable from that of a normal nulliparous uterus apart from its increase in size.

This increase in the uterine wall is due, I think, to a pure hypertrophy. All these patients suffer from dysmenorrhoea, which is a manifestation of excessive muscular contraction due to the uterus trying to expel this thickened endometrium, which swells to enormous proportions in each pre-menstrual period. This excessive muscular contraction each month carried on for many years gradually produces hypertrophy of the muscular wall. Patients of this type are brought to us in middle life with the symptoms of haemorrhage and dysmenorrhoea extending over many years, but the symptoms are due to changes in the endometrium, and the thickening of the wall is merely due to overwork.

#### GENERAL DISCUSSION.

Mr. W. W. KING (Sheffield) said that they had listened to a paper which was a very notable advance in the physiology of menstruation, and one which must be of great value in the solution of the problems of excessive menstrual bleeding. He was very glad to note that Professor Beckwith Whitehouse had, so to speak, "frozen out" the term "endometritis" from his address. The word had no exact meaning, either clinical or pathological, but it had been used as a scrap-heap for diagnosis and an excuse for curetting. Its use had kept back the proper conception of menstrual anomalies for years past. On the question of terminology to which Professor Fletcher Shaw had referred, might they not abandon the use of the phrase "chronic metritis," which was now used as a generic term for all cases of excessive bleeding with an approximately normal uterus? The evidence of chronic inflammation of the myometrium was only rarely found, and even then was often not very convincing, whereas the excess of elastic tissue which Professor Fletcher Shaw had shown to be diagnostic of chronic subinvolution was constantly present and easily demonstrable. It would seem better, therefore, to replace "chronic metritis" by "chronic subinvolution," and to restrict the use of the former term to those uncommon cases in which real chronic inflammatory changes could be shown to exist in the uterus after removal, or at least to nulliparous women with clinical evidence of chronic inflammation.

In regard to treatment of functional menorrhagias, Professor Beckwith Whitehouse's investigations seemed to indicate that their hope lay in the direction of lutein extracts. Mr. King thought that these should be given by hypodermic injection, and not by the mouth. The vagaries of thyroid medication were an example of how difficult it was to get consistent results with endocrine extracts—though thyroid extract was one of the few which could be given by the mouth. The menorrhagias of early menstrual life could sometimes be effectually cured by a single injection of one of the blood-coagulating serums now

on the market. It was not, of course, safe to repeat the injection, on account of the danger of protein shock, but permanent results might follow a single injection. He had found the cotarine series of drugs to be the most useful empiric remedy. Radium had not given as good results as was at first expected. In 13 per cent. of the cases treated at the Jessop Hospital for Women there had been recurrence of the bleeding, using doses of 1,300 to 2,000 m.c. hours. He asked Professor Beckwith Whitehouse if he thought that the endometrium had any complementary function with the internal secretion of the ovaries. Though it was known that radium destroyed the endometrium without acting on the ovaries, yet 86 per cent. of the radium series of patients mentioned had menopausal symptoms. He was unaware of any work on these lines, but there appeared to be some grounds for supposing that endometrial extracts might be of use in controlling the hot flushes of the artificial climacteric.

Dr. RHODA H. B. ADAMSON (Leeds) had some questions to ask with reference to the explanation of certain clinical phenomena on the assumption that menstruation was a missed pregnancy. The first of these was the occurrence of three to four days' menorrhagia in schoolgirls of 17 and 18 years of age when sent from inland districts to boarding-school at the seaside, such menorrhagia not reacting to medical treatment while at school but always clearing up at once on return home. There was also the presence of amenorrhoea or greatly decreased menstruation in professional acrobats and ballet dancers; and lastly, the occurrence of apparently normal regular menstruation in cases of repeated pregnancy in certain patients during the first two or three months.

Professor J. S. ENGLISH (Singapore) strongly endorsed the proposal to classify these types of haemorrhage in accordance with the suggestions of Professor Whitehouse. In Singapore the temperature all the year round ranged between 75° and 85° F. Menorrhagia among the white population was common, but he had seen two patients, both of them the wives of prominent Government officials, who had suffered from complete amenorrhoea during their stay in the East. He thought that x-ray treatment applied to the ovaries gave good results in cases of excessive haemorrhage.

Mr. L. C. RIVETT (London) asked what were the clinical differences between subinvolution and chronic metritis. He had not distinguished between them, except that he had recognized the large flabby uterus and the small hard uterus. He would like to know what was the correct treatment. He understood Professor Whitehouse to say that curettagé frequently cured this condition. If the pathology was as described by Professor Fletcher Shaw, he did not see how curettagé could have any effect whatsoever on the elastic or fibrous cushion surrounding the vessels. He had seen patients temporarily relieved by curettagé, but the bleeding returned. He now performed hysterectomy for both conditions, and wished to know if he was right in doing so.

Mrs. ALETHEA J. EAMES (Glynceiriog) said that regarding the correlation between thyroid gland and uterine function, in mountain valleys they saw many cases of enlarged thyroid of puberty, accompanied by simple menorrhagia. The results of internal gland medication varied. She asked whether Professor Whitehouse could throw any light on the subject.

Mr. MASLEN JONES (Wolverhampton) stated that in cases of severe haemorrhage at puberty he had found radiation over the ovarian region, in small repeated doses at intervals of one month, most useful in lessening and finally curing the excessive loss. In certain cases, however, apparently the ovaries were quite unaffected by the treatment; in these radiation had then been applied to the thyroid with permanent beneficial results. Referring to cases of haemorrhage due to subinvolution and metritis, he had found, if the condition was not of long standing, that curettagé, followed by the repeated intrauterine injection of sterile glycerin, most efficacious. In these cases

the arrested involution seemed to be restarted, the uterus reverted to its normal size and consistency, with a permanent cure of the symptoms.

Mr. T. H. RICHMOND (Stoke-on-Trent) said that, following his usual custom, he sent all his curettings to the pathologist for his opinion. He thus had the information whether he was dealing with a malignant condition or not. There was, however, what appeared to be a rather rare condition—namely, the piling up of endothelial cells in the glands without breaking down of basement membrane. It was not in the truest sense malignant, but locally there appeared to be invariably a recurrence of the bleeding after curettage. It was in these cases that radium did so well.

Dr. COMRIE-SHARP (Capetown) said that, coming as he did from a country where nature had endowed women with very normal pelvises, he had enjoyed the advantage of hearing the experiences of men who were continually coming across cases of a kind which they in South Africa saw either only very occasionally or not at all. He thought that the opening papers were of such depth and merit that very careful consideration should be given to them before an opinion could be pronounced.

The PRESIDENT, on behalf of those present, thanked Professor Beckwith Whitehouse for his very interesting address, and Professor Fletcher Shaw for his lucid description of the various changes that were found in the uterus in those cases which formed the subject of the morning's discussion. It must be very rare for a Section to have present the two greatest authorities on the subject dealt with. He supported Professors Beckwith Whitehouse and Fletcher Shaw in their endeavours to disentangle the nomenclature of uterine haemorrhage. The terms "menorrhagia," "metrorrhagia," and "endometritis" should be abolished by all teachers, examiners, and writers of textbooks, and such terms as had been suggested substituted. He did not feel in a position to criticize Professor Beckwith Whitehouse's paper; much of it dealt with new work and would require very careful studying. As regards treatment, he had had great success with radium, which he preferred to x rays, principally because he always curetted the uterus first and so could be sure, so far as it was possible to be sure, that there was no malignant disease. He had known a case of carcinoma of the body of the uterus, in ignorance of this condition, x-rayed for haemorrhage, with disastrous results. He had obtained most successful results with thyroid and no results at all. Before treatment by radium and by x rays to the thyroid had been practised he had obtained very excellent results by utericlepasty, which had the advantage over the other available method of hysterectomy, in that so much of the uterus was conserved that a possibility of pregnancy remained, and the young patient of 20 on whom he had performed utericlepasty gave birth to an 8 lb. child four years later with a normal puerperium. He was interested to hear Dr. Adamson's remarks about acrobats and that she did not include ballroom dancers in this category; he thought that the acrobatic exploits of some ballroom dancers he had seen would take some beating, and he had had to treat two such performers for very excessive periods.

Dr. FLETCHER SHAW, in reply, endorsed all that had been said in favour of a more rational and a more accurate nomenclature. He agreed that it was impossible clinically to distinguish between chronic metritis and subinvolution. The majority of cases were undoubtedly subinvolution, but now and then the condition was found in nulliparous women. In answer to the question about excessive bleeding at puberty, he did not think that the sea air had anything to do with it; it was excessive stimulation of the nervous system. These girls were nearly always working up for an examination. If they were removed from school and relieved of the strain they almost invariably got quite well. There was no other cure for subinvolution but another pregnancy followed by normal involution. Temporary benefit might accrue from curetting combined with pituitrin to stimulate the uterine muscle. After the age of

40 it was advisable to get rid of the uterus altogether, either by total hysterectomy or radium. He was rather afraid of radium, as no one knew exactly how it acted. He favoured total hysterectomy, as these cases were nearly always complicated by the association of cervical lacerations and so forth. In dealing with every case of excessive haemorrhage they must always satisfy themselves that they were not dealing with malignant disease.

Professor BECKWITH WHITEHOUSE, in his reply, said that most of the questions had already been answered. He entirely agreed with Mr. King that the term "endometritis" should be banished for ever. Dr. Eames had raised the question of giving thyroid in excessive bleeding at puberty; it was a case not of increasing the amount of thyroid secretion but inhibiting it, and this could best be accomplished by x rays. The question of when to inhibit or when to stimulate the activities of the endocrine glands would only be satisfactorily solved by a complete investigation of the basal metabolic rate in health and disease. He confessed he was beaten by Dr. Adamson's question about the amenorrhoea of acrobats. All he could say was that manual labour appeared almost to abolish menstrual difficulties. He agreed with the President that utericlepasty was a most useful measure, and had had considerable success with it himself. He looked upon curetting as mainly a diagnostic measure: it must certainly not be regarded as the last word in the treatment of uterine haemorrhage. When examining the curettings the pathologist should be acquainted with the menstrual rhythm of the particular individual patient whose case was under consideration.

## A GOOD DIET AND A BAD ONE: AN EXPERIMENTAL CONTRAST.\*

(With Special Plate.)

BY

ROBERT MCCARRISON, C.I.E., M.D., D.Sc., F.R.C.P.,  
LIEUTENANT-COLONEL I.M.S.,

DIRECTOR, DEFICIENCY DISEASES INQUIRY, INDIAN RESEARCH FUND  
ASSOCIATION, PASTEUR INSTITUTE, COONOR, SOUTH INDIA.

I HAVE on former occasions<sup>1</sup> referred to the high degree of physical efficiency attained by those Indian races—Sikhs and certain Himalayan tribes—whose food consists of coarsely ground whole-wheat, milk, milk products, tubers, roots, green leafy vegetables, and fruit, with meat occasionally. In physical development, hardihood, and powers of endurance they are probably unsurpassed by any other races of mankind. The conclusion was drawn that this is due, in the main, to the high nutritive quality of whole-wheat, as compared with other staple food-grains (such as rice), and to the manner in which these races combine whole-wheat with other protective foods—milk, milk products, fruit, and green leafy vegetables. This conclusion has now been subjected to the test of experiment, and the effects, on omnivorous animals, of "a good diet," constituted as above, have been compared with those of "a bad diet," such as is used by many Western people of the poorer classes. The results of this comparison are recorded in the present paper.

### THE EXPERIMENT.

Two colonies of half-grown rats were employed, each comprising 20 animals, of which 12 were males and 8 were females. They were selected from among ten or twelve litters of approximately the same age, and were so distributed between the two colonies as to ensure, as far as possible, that the growth-potential of the two groups would be alike. The aggregate weight of the animals in each colony was the same—2,540 grams (See chart). They were housed in the same room, caged in a precisely similar way, and were equally well tended.

One colony received "a good diet," designed to resemble that eaten by the Sikhs. It consisted of "chapatties,"

\* Abstract of a paper appearing in the January, 1927, number of the *Indian Journal of Medical Research*. Published by permission of the Director-General, Indian Medical Service.

made of whole-wheat flour (atta); uncooked vegetables (cabbage, potato, carrot); fresh fruit; sprouted "gram" (legumes); butter; fresh whole-milk; water; and fresh meat occasionally. Ten grams of butter, spread over the chapatties, were given for the whole colony every third or fourth day. Milk was supplied in amounts of approximately 300 c.cm. daily, and fresh meat once a week to the amount of two ounces for the whole colony. Liberal quantities of chapatties, sprouted gram, uncooked vegetables, and tomato—to take the place of fruit—were given, so that the animals could select for themselves the amount of each they cared to eat.

The second colony received "a bad diet" designed to resemble that eaten by many Western people of the poorer classes. It consisted of white bread, made from American white flour; vegetables—cabbage, carrot, potato, etc.—cooked in water to which pinches of sodium bicarbonate and common salt were added; a substitute for margarine, consisting of coco-nut oil to which 100 grains of boric acid were added to every pound of the oil; tinned meat, which had been exposed to formaldehyde vapour for several hours; tinned jam; tea, well sweetened with sugar, to which was added enough milk to give it the customary tinge; and water. The boracized coco-nut oil was lightly smeared on slices of the white bread and covered with a liberal coating of jam. The potted meat was given in like amount to the fresh meat in the first colony—two ounces weekly. Of the other ingredients of the food—the bread-and-jam, the cooked vegetables, the tea-and-sugar, and the water—the animals were allowed to eat and drink as much as they liked. They acquired an extraordinary liking for the tea, the colony consuming as much as 600 c.cm. daily, and therewith approximately 20 grams of sugar and 20 c.cm. of milk.

It will be noted that this diet contained two of the commoner food preservatives so widely used in Western countries<sup>2</sup>—boric acid and formaldehyde. The former is commonly present, sometimes in large amounts, in butter, margarine, cream, imported liquid eggs, sausages, potted meat, potted fish, and some beverages; while it is also used for packing bacon and hams.<sup>2</sup> As much as 175, 140, and 110 grains of boric acid per pound have been found in margarine, butter, and bacon respectively; the amount in the first two is usually 0.5 per cent., or 35 grains per pound.<sup>2</sup> I added 100 grains to the pound of coco-nut oil in order that other sources of boric acid—bacon, liquid eggs, sausages, etc.—not included in the above diet, but commonly included in the dietaries of Western people, might be covered, so that the amount of boric acid ingested by the rats might be approximately proportionate to that ingested by these people. The potted meat was exposed to formaldehyde vapour in order to simulate the Langley process of treating chilled meat for export. In all probability the tinned jam contained sulphurous acid as a preservative<sup>2</sup>; so that in addition to the faults in composition and in quality of this diet (insufficiency of vitamins, of suitable proteins, and of certain mineral salts, and excessive richness in starch and sugar) there were present in it several food preservatives the effects of which on the animal organism may not have been negligible.

The experiment was continued for six months. During its course the animals were kept scrupulously clean, were comfortably bedded in fresh straw, and were given sun baths of two hours' duration—while in their cages—twice a week.

#### RESULTS OF THE EXPERIMENT.

##### 1. Mortality.

On the termination of the experiment there were 17 animals alive and well in the colony which received the "good diet"—10 males and 7 females. In the colony which received the "bad diet" 11 animals were alive at the end of the experiment—5 males and 6 females. The mortality from all causes in the former colony was thus 15 per cent., in the latter 45 per cent. But whereas the survivors in the first colony were well grown, sleek-coated, strong and active, those in the second colony were ill-

grown, poor-coated, weakly and listless. The differences in size and appearance of the animals in the two groups are illustrated in the accompanying photographs (Figs. 1 to 4), which were taken during the sixth month of the experiment.

##### 2. Causes of Death.

Of the 3 animals which succumbed in the well-fed colony one died from injury to the abdomen; at post-mortem examination it was found to be excellently nourished; its organs were in perfect health. A second animal died of pneumonia; the gastro-intestinal tract was not diseased.\* The third died from causes which I was unable to discover at post-mortem examination; a small cyst containing an embryo tapeworm was present in the liver.

Of the animals which died in the ill-fed colony 3 were killed and eaten by their fellows—so completely eaten in each case that little or nothing remained for post-mortem examination. The

fact that they were killed shows that they were in a weakly condition.

[At one time during the course of the experiment (see chart) I feared that cannibalism—that sure sign in rats of a faulty diet—might put an end to the experiment. Resort had, therefore, to be made to separating each animal in this group from its fellows every night. Later, a small quantity of fresh vegetable food was given, two or three times a week, in addition to the diet above mentioned, when cannibalism ceased.]

The immediate cause of death in the other 6 animals was bronchopneumonia; and this at a time when bronchopneumonia was so rare in my stock animals that only three cases of the disease occurred during the six months in a rat population which averaged 375 animals daily. One consequence, therefore, of the "bad diet" was to lower the resistance of the lungs to attacks by microbial agents of disease—a consequence of faulty food, deficient in vitamins, which has already been emphasized by Cramer.<sup>3</sup>

##### 3. Other Post-mortem Findings.

Of these, the most constant and the most important were changes in the gastro-intestinal tract which impaired its functional capacity. In illustration of this point I append

\* Owing to inadvertence the cage containing this animal was exposed to draught during a spell of cold and wet weather.

Chart showing (a) gain in aggregate body weight of the colony fed on the "good diet" and the mortality in this colony; (b) loss in aggregate body weight of the colony fed on the "bad diet" and the mortality in this colony. The 17 survivors in the first colony increased in body weight by approximately 46 per cent. The 11 survivors in the second colony lost in body weight by approximately 6 per cent. The average age of the rats at the beginning of the experiment was eighty days.

the notes of two cases dictated at the time the *post-mortem* examinations were made:

"On opening the abdomen the first thing observed is the extreme dilatation and thinning of the whole gastro-intestinal tract; atony of the bowels; ballooning and transparency; intestinal stasis; giving the appearances now so familiar to us in deficiently fed animals, and first observed in pigeons and monkeys in 1919."<sup>1</sup>

Again in another case:

"This case presents an extraordinary contrast to all other rats' intestines seen up to date. The lumen of the bowel is very much narrowed, the bowel being in its whole course hardly thicker than a piece of grocer's string. There is no distension of the bowel nor 'air-locks.' Intestinal stasis is marked; the lower part of the bowel is filled with hard, oval, faecal masses situated one above the other, which, with the attenuated bowel between them, resemble a string of beads strung at bead-distance intervals. The stomach is very small, and is not dilated; it is filled with coffee-ground-like material, some of which washes off in water, but much of which is adherent to the congested mucous membrane; and can be removed only by scraping. About the middle of the proximal portion of the stomach there are three mammiform areas, each having a small crater-like depression at the top."

These areas, which may be either villiform or mammiform, were found in this situation in 3 of the 6 animals in which *post-mortem* examination was made, but never, so far, in well-fed controls. On histological examination they were seen to be papillomatous outgrowths of the stratified epithelium lining the proximal part of the stomach. Their appearance is illustrated in the photomicrographs (Figs. 3 and 4). These notes will serve to indicate that the diet on which this colony was fed was such as favoured the production of an unhealthy and inefficient state of the gastro-intestinal tract, and an abnormal growth of epithelium in the proximal portion of the rat's stomach.

#### 4. Body Weight.

The difference in body weight of the two colonies is sufficiently indicated by the photographs. Aggregate weight curves are, however, given in the chart. Starting from the same point at 2,540 grams, it will be noted how the two curves diverged: the aggregate weight of the well-fed colony rose steadily; that of the ill-fed colony fell steadily. At the points at which deaths occurred in either colony an arrow indicates the event. The fall in the aggregate weight curve of the ill-fed colony was, of course, due mainly to losses by death; but the chart illustrates in a striking way the extent to which the ill-fed colony suffered.

#### CONCLUSION.

This experiment demonstrates that a diet composed of whole-wheat, milk, milk products, sprouted legumes, uncooked vegetables and fruit, with fresh meat occasionally, far surpasses in nutritive value that composed of white bread, tea, sugar, margarine, jam, boiled vegetables, and tinned meat, to which the common food preservatives—boric acid, formaldehyde vapour, and sulphurous acid—are added. The former promotes physical efficiency and health, but the latter gives rise to stunting of growth, to physical inefficiency, and often to disease. The maladies of which the bad diet is so apt to lay the foundation are lung disease and gastro-intestinal disease. I have repeatedly drawn attention to the influence of faulty and ill-balanced food in causing the gastro-intestinal diseases which are so common at the present day.<sup>2</sup> The results of this experiment furnish additional proof of this influence, and suggest also that the common food preservatives may contribute their share to the harmful effects of such a food. The high incidence of lung disease in the ill-fed group emphasizes no less strikingly the influence of what one may call the "white-bread-margarine-tea-sugar diet" in favouring the operation of pathogenic agents which attack the lungs.

## Memoranda:

### MEDICAL, SURGICAL, OBSTETRICAL.

#### NEW SERUM PEPTONE IN ASTHMA.

My communications on this subject to the *BRITISH MEDICAL JOURNAL* (vol. ii, 1924, p. 575, and vol. i, 1925, p. 448) now require alteration. When the solution of peptone was added to the fresh blood and incubated at 37° C. a clear peptonized serum gradually formed, which was usually pipetted off on the following day. But last winter this no longer occurred. An insoluble clot, whitish in colour, formed over the blood. It was evident that plasma as well as serum was being extruded. Adding to the fresh blood a minute quantity of calcium chloride made matters no better. It is clear that the peptone must have undergone a change of some sort. A fresh batch of Armour's peptone (No. 2) showed the same thing.

The serum peptone could be made, however, by allowing the blood to clot, drawing off the serum, and adding peptone in powder or in solution, then incubating and adding phenol.

Since last spring I have been making the serum peptone by a new method. The blood is run directly from the needle into a four-ounce sterile glass tube, which is made half or three-quarters full. It is then allowed to stand at room temperature until next day. As the patient is not allowed any food for five hours before the bleeding the serum is clear. It is pipetted off and some agar solution added to it.

The agar solution is prepared by mixing one part of agar with 1,000 of water (1 grain, 1,000 minims). This is well boiled and allowed to cool. No gel is formed, but should a little clot be present it is removed. One volume of this solution is shaken up with 5 volumes of the serum and the mixture incubated at 37° C. for about an hour. The peptone powder (Armour No. 2) is then added to the mixture in 4, 5, or 6 per cent., according to the patient, slightly agitating, and it is again incubated for an hour. By this time the peptone will all be thoroughly dissolved, and on adding 0.5 per cent. phenol the preparation is ready for use. If the peptone powder is doubtful as regards sterility (which it should not be) it may be heated to 100° C. for a time. I have tried trikresol instead of phenol, but it is not quite so good. Dilute the phenol with five or six times its volume of water and rapidly shake on adding it.

The preparation is given in 1½ c.cm. doses intravenously every three, four, or five days, going up gradually to 3 or 4 c.cm. The above agar solution is only one-fifth of the strength used experimentally by Bordet, as it was found that serum can be toxified with agar one-tenth of the strength used by Bordet. Bordet's agar forms a gel also on cooling. Novy and his colleagues found that keeping the serum for twenty-four or thirty-six hours before adding the agar had no effect on the toxicity. Hence, it is unnecessary to centrifugalize the blood.

The effect of this solution, which must be very carefully prepared and administered, is very good in cases where peptone alone has proved unsatisfactory.

London, W.1.

A. G. AULD, M.D.

#### ACUTE INTESTINAL OBSTRUCTION DUE TO HYDROCEPHALIC CHILD.

The following case is recorded because of its unusual features and complications.

A married woman was admitted to the Bristol General Hospital on January 23rd, 1926. She was eight months pregnant and complained of intractable vomiting. Her previous history was that she had had Caesarean section performed for her first child in 1921 and had had an induction at eight months for her second in 1924; neither of these children survived. She was due for admission at a slightly later date for induction for her present pregnancy.

On admission she had a normal temperature but a persistent pulse rate of 120. There was no abdominal rigidity and no marked distension; the only tenderness was over the uterus itself. The presenting foetal vertex was on the brim. Urine examination showed the presence of diacetic acid but no albumin, and as there were no other evidences of toxæmia I put the presence of diacetic acid down to her persistent vomiting and consequent carbohydrate starvation. A fair result was obtained with an enema.

<sup>1</sup> From Baird and Tatlock.

The vomiting persisted in spite of treatment, and gradually the passage of faeces ceased though flatus was still passed in small quantity with turpentine enemata. On the second day after admission the presenting part was firmly fixed in the brim and obstruction became absolute. I decided to induce labour by rupturing the membranes, hoping that this would relieve the obstruction, as there seemed no other cause but the pressure of the presenting part. I induced labour at 5 p.m. on January 25th without anaesthesia; very little liquor escaped, but labour commenced later in the evening. At 2 a.m. on the next morning the patient's condition was very bad; vomiting had recommenced, the pulse was 160, the cervix was half dilated and the presenting part was in the pelvis. I determined to deliver the child through the vagina as her general condition seemed to preclude any abdominal operation. Under anaesthesia I found that the presenting part was the advanced part of a huge hydrocephalic head, the greater portion of which was above the brim, the only bony portion being in the pelvis. I immediately perforated and delivered the child quite easily, but this was followed by an alarming haemorrhage. I put my hand into the uterus in order to deliver the placenta, when I found that my hand went through the uterine wall into the abdominal cavity. The patient's position was changed immediately and I opened the abdomen, to find the placenta floating free in the abdominal cavity, which was filled with fresh blood and old blood clot; there was a large rent in the anterior wall of the uterus corresponding to the old Caesarean scar. I removed the placenta and then performed a subtotal hysterectomy, leaving a drainage tube in the pouch of Douglas on closing the abdomen. For the next few days the patient's condition was critical on account of the shock and haemorrhage, but she eventually made an excellent recovery. There was never any sign of sepsis, while the obstruction was immediately relieved by the operation.

That the obstruction was due to the hydrocephalus I think there is no doubt, as it filled the pelvic brim completely like any soft tumour and pressed on the intestine. Against a toxæmia is the presence of absolute constipation. The rupture of the Caesarean scar had evidently commenced prior to my intrauterine manipulations, as around the scar and in the abdomen there was a considerable amount of organized blood clot, but it is probable that it completed the tear in my efforts to dislodge the placenta, which was attached to the area of the scar.

As an eventful obstetrical history I think that this case will be hard to beat.

Honorary Assistant Obstetrician and Gynaecologist,  
Bristol General Hospital.

## Reports of Societies.

### INTRACRANIAL TUMOURS.

THE first meeting of the winter session of the Section of Neurology of the Royal Society of Medicine was held on October 14th, when Sir JAMES PURVES-STEWART, who had been elected President for the year, delivered his presidential address, on intracranial tumours and errors in their diagnosis.

The President confined his remarks on intracranial tumours to purely personal experiences. While fully aware of the important contributions to this branch of neurology by various workers, he preferred to omit reference to the literature of the subject. His observations were based upon notes of 250 cases of cerebral tumour, in 119 of which the localization of the tumour was subsequently verified either by operation or necropsy. He showed many lantern slides illustrating brain preparations and displaying cerebral tumours or cysts in various parts of the brain, including cortical and subcortical tumours of the frontal, parietal, and occipital lobes, and tumours of the mid-brain, the basal ganglia, the pons and medulla, the optic and auditory nerves, the Gasserian ganglia, the pituitary region, and the cerebellum. Interesting specimens of tumour of the lateral ventricles and the cisterna magna were also shown. It was often the case that a cerebral tumour of large size gave rise to surprisingly few physical signs. Prefrontal tumours were sometimes associated with nystagmus and unilateral ataxia, and might therefore be mistaken for homolateral cerebellar tumours; this error had occurred in two of the cases of the series. On the other hand, cerebral tumours were sometimes accompanied by no other signs than nystagmus. More than one tumour might occur in the same brain and thus lead to errors of diagnosis or localization. Some cases of disseminated sclerosis simulated cerebral tumour, especially if associated with

intracranial haemorrhage; one such case was that of a girl, aged 17, with a history of failing vision (optic atrophy), attacks of unconsciousness associated with transient hemiplegia, mental apathy, and a pronounced increase in weight. This patient, with some justification, was considered to be suffering from a cyst in the pituitary region, which probably involved the posterior lobe of the pituitary gland. At autopsy, however, a condition of disseminated sclerosis was found, with an area of haemorrhage into the right caudate nucleus. Tumours involving the basal ganglia or mid-brain might be mistaken for the Parkinsonian type of encephalitis lethargica; this error had occurred in one case. Serous meningitis with internal hydrocephalus secondary to otitis media might give rise to symptoms and signs closely resembling those of cerebral tumour, especially if optic neuritis was present. One interesting case was that of a woman who complained of headache, vertigo, and nausea only when sitting up or standing; on lying down these symptoms at once disappeared; at the necropsy a tumour of the lateral ventricles was found. Sir James Purves-Stewart suggested that the symptoms experienced by the patient when the head was erect were due to the tumour hanging down in the ventricles and blocking the foramina of Monroe; in the supine position the tumour probably fell backwards and the foramina were not occluded. In another case, when tumour of the cisterna magna was present, the patient showed no symptoms or physical signs attributable to the pons or medulla, but had a spastic condition of both upper limbs. Pachymeningitis haemorrhagica might also be mistaken for cerebral tumour; since the Wassermann test was introduced as a routine examination, however, this error was less frequent. In conclusion, the President said that errors of diagnosis were divisible into two classes: (1) avoidable errors, such as those resulting from inadequate or incomplete examination, lack of a sufficiently detailed history, and attempting to fit in with a preconceived notion of the patient's case symptoms that developed subsequently; (2) unavoidable errors—in the early stages of cerebral tumour the physical signs might be inconspicuous, and even later, localization difficult, and sometimes impossible.

A vote of thanks to Sir James Purves-Stewart for his interesting address was passed, on the proposition of Professor EDWIN BRAMWELL (Edinburgh), seconded by Mr. DONALD ARMOUR (London).

### CHOLECYSTITIS.

At a meeting of the Brighton and Sussex Medical-Chirurgical Society on October 7th Dr. E. RIVAZ HUNT gave his presidential address on cholecystitis.

Dr. Hunt said that according to Hurst cholecystitis was the most common of all chronic abdominal disorders, probably occurring in at least 20 per cent. of all persons. It was probable that with a keener watch for this condition many complaints of bilious attacks, indigestion, flatulence, or even of that much abused term "influenza," could be attributed to their real cause—the presence of cholecystitis. Gall stones, found after death in at least 10 per cent. of all persons dying after the age of 20, were probably almost always secondary to cholecystitis, though the latter might have ceased long before the presence of the gall stones was recognized, and might also exist without the presence of gall stones. He emphasized the importance of recognizing this disease as a focus of chronic sepsis, either occurring alone or in conjunction with septic foci in the more common situations, such as the teeth, tonsils, and nasal sinuses. After briefly reviewing the anatomy of the gall bladder and its nerve supply, and mentioning the importance of the close relation in the spinal cord of the areas from which the gall bladder, liver, and stomach were innervated, he discussed the physiology of this organ. It was probable that the gall bladder acted as a pressure bulb to regulate the flow of bile into the duodenum rather than as a storehouse for bile, which was formerly thought to be its chief function. Cholecystitis was invariably microbic in origin, and therefore any agent which lowered the resistance of the mucous membrane of the gall bladder was a predisposing cause of infection. Streptococci isolated from infected teeth and tonsils in cases of cholecystitis

had often a specifically selective action on the gall bladder when inoculated into animals. Infection by the lymphatic path was probably the most important route. Inflammatory changes in the liver were a constant accompaniment of cholecystitis. Duodenal ulcer, appendicitis, and typhoid fever might lead directly to infection of the gall bladder. Factors of contributory or predisposing importance in provoking cholecystitis were conditions which reduced the vitality and resisting power of the gall bladder and biliary ducts, such as trauma, previous attacks of cholecystitis or gall stones, local diseases of the intestinal tract which might act as a source of bacterial infection, and general disorders, such as nephritis, in which complicating or terminal infections were common. Other predisposing causes were gall stones, tumours, foreign bodies such as worms, catarrh within the ducts, or tumours, compressing kinks or cicatrices, or general conditions leading to biliary obstruction or stagnation of bile in the gall bladder, such as sedentary habits, obesity, abdominal tumours, pregnancy, and tight lacing. A biliary infection complicating or following pneumonia, influenza, and such diseases might be due, not to the specific cause of the general infection, but to pyogenic cocci or the colon bacillus, the original infective agent or its toxin perhaps having prepared the way for the secondary invader. It was probable that symbiosis in combination with focal sepsis and some form of protein sensitization had an important bearing on the causation of many diseases, such as diabetes, Hodgkin's disease, eczema, and the various dermatoses; it was even possible that the cause of cancer might eventually be found in some combination of these three factors. Cholecystitis appeared to be more common in adults, and especially in those who were unable to take regular and satisfactory exercise. The onset was usually gradual, and as a rule there was little or no pyrexia, except at intervals when short attacks of a characteristic type might occur. Flatulent dyspepsia was the most prominent symptom, usually coming on immediately after meals, though, when associated with reflex hyperchlorhydria, it simulated the hunger pain of duodenal ulcer, beginning two or more hours after a meal, and being then relieved by food, alkalis, or vomiting. Vomiting was uncommon, but nausea was very frequently present. Indeed, cholecystitis was the most common cause of chronic nausea. Some irregularity of the bowels might occur during the attacks of pyrexia. Jaundice was not a marked feature. The pain of cholecystitis was not infrequently a recurrent gastric pain, often worse at night, but owing to the close association of the centres in the spinal cord innervating the stomach, liver, and gall bladder, the irritable focus in the cord might not be due necessarily to a gastric lesion, but might arise from disease of a neighbouring organ. Viscero-sensory accompaniments of cholecystitis included superficial and deep soreness in the right upper region of the abdomen, right subscapular and interscapular pain, and tenderness over the middle dorsal spines and along the course of the eleventh rib on the right side. In some cases of cholecystitis in which the gall bladder was situated abnormally high, the inflammation of the gall bladder might extend to the under surface of the diaphragm and give rise to many of the signs and symptoms of subphrenic abscess; it might even masquerade as a pulmonary affection with slight dullness at the base of the right lung, râles, and slight pyrexia.

In considering the accessory means of diagnosis, such as the  $x$  rays, functional test meals, and examination of the bile and duodenal contents by the use of the Einhorn tube, Dr. Hunt emphasized the importance of remembering that such newer methods should be considered as accessory only, and not as short cuts to diagnosis, to the exclusion of the older and simpler methods, including study of the history of a case and the intelligent use of the eyes, ears, and hands. Lewis's mydriatic test for diagnosing acute pancreatitis was described. The treatment of acute cholecystitis was surgical. It might be divided broadly into two classes: (1) Cases in which secondary complications, such as gall stones, or evidence of secondary septic troubles elsewhere, were present; for these operation was the ideal course. (2) Cases in which secondary complications were absent, or in which operation was declined, or for some

other reason was inadvisable; for these medical treatment might be tried first. An important point was the removal of any primary focus from which infection might be conveyed to the gall bladder. Oral sepsis, tonsillitis, infection of the accessory nasal sinuses, chronic appendicitis, pelvic infectious in women, and *Bacillus coli* infections must be looked for and treated. An attempt must be made to treat the gall-bladder infection by means of biliary antiseptics and provision of adequate drainage. Large doses of urotropine combined with alkalis, given in the manner advocated by Hurst, might be used; hexamine, combined with hexamine salt of cholic acid, was sometimes efficacious. Salicylates or aceto-salicylic acid in large and regular doses had been advocated. Magnesium sulphate given in concentrated solution by the mouth promoted biliary drainage. The importance of exercise, especially horse-riding and rowing, was insisted upon. The diet should be carefully supervised so as to avoid or restrict those articles of food which contained or produced cholesterol.

### JAMES MACKENZIE INSTITUTE FOR CLINICAL RESEARCH, ST. ANDREWS.

THE Winter Session of the James Mackenzie Institute was opened on October 5th, when the Honorary Director, Dr. Maitland Ramsay, gave an address. In the eye, he said, physiological and pathological processes can be directly observed as they occur in a state of nature (as distinguished from experiment under artificial conditions), and since it is a fundamental principle that similar structures behave alike in all parts of the body, the phenomena observed in the eye are a valuable index of the conditions obtaining in other organs. With this principle in mind he proceeded to draw attention to some analogies and contrasts between the non-striped muscle of the eye, which can be directly observed, and that of the heart and other hollow viscera. The nerve supply of the non-striped muscle of the eye is derived both from the sympathetic and the cranio-autonomic systems—the dilator muscles, whatever their position, having a sympathetic supply, while the constrictor muscles are innervated by the cranio-autonomic. These supplies are anatomically and functionally distinct.

As a result of this reciprocal innervation (Dr. Ramsay continued) the pupil is never at rest, the two opposing actions maintaining an equilibrium adjusted not only to the influence of light, but to afferent impulses from all over the body. The pupil, for example, varies with respiration, while it contracts during cardiac systole and dilates during diastole. In the eye the dissociation of structures concerned in contraction and dilatation is so complete that a study of the reflexes of the pupil ought to throw light on the mechanism of the heart beat and the peristalsis of the bowel. There was an analogy between the nerve supply of the iris and of the heart, sympathetic and cranio-autonomic nerves opposing one another in each instance—contraction of the pupil is analogous to slowing, and dilatation to quickening, of the heart. In their reaction to drugs the two organs show a similar analogy. Atropine dilates the pupil and quickens the heart by paralyzing cranio-autonomic endings. Adrenaline produces similar effects by stimulating the sympathetic. The action of physostigmine on the eye and digitalis on the heart were also compared. Loss of the light reflex in Argyll Robertson pupil is no evidence of disease of the iris itself any more than heart block is evidence of disease of the ventricular muscle. The severe pain which accompanies spasm of the iris is comparable to that accompanying spasm of non-striped muscle elsewhere—in the heart, the intestine, and the ureter. The process underlying its production is in each case the same. The ciliary muscle and the heart muscle are two muscles of the body which can be overworked by an effort of will—the pain and hyperalgesia of eyestrain resulting in one instance and angina pectoris in the other. Both can be restored by physiological rest. Each muscle hypertrophies when subjected to prolonged strain and both become, at the same time, more easily broken down.

The lecturer gave many other examples of the physiological analogy between the non-striped muscle of the eye and of other organs.

## Reviews.

### EDUCATIONAL PSYCHOLOGY.

MR. CHARLES FOX, the director of the training of teachers and lecturer in educational psychology in the University of Cambridge, has produced a first-class book on the problems and methods of education, entitled *Educational Psychology*.<sup>1</sup> His aim has been to consider the contribution made by experimental psychology to the elucidation of educational problems. A vast amount of experimental work has been done during the last twenty-five years, and not a little confusion and exaggeration has resulted from too much undigested material. The aim of the author has been to attempt a conspectus of the present position, more especially as it is directly related to educational matters. The book is, however, much more than a survey, it is a critical exposition. The author recalls that much good work was done before the recent revolution came about, for wisdom did not delay its entrance into the world until the reign of experimental psychology began; the experience of practical teachers gave, and still gives, them an insight into the mentality of youth obtainable in no other way. Nevertheless, the value of experimental observation cannot be gainsaid, and the science of education must take into account the evidence acquired by exact methods.

In this book the history of the subject is well presented and related to the new work; the result is illuminating. The critical attitude of the author is refreshing. In the chapter on habit-formation he shows that there is no ground for the belief that acquired impulses are all derived from inherited tendencies to action. Hume first formulated the belief that reason could never of itself be a motive to conduct, but was confined in its operation to directing the conflict of inherited impulses. The recent tendency has been to assert the belief that only propelling and never attracting forces determine human conduct; that we can never acquire a new impulse to action, but that all the energy is derived from inherited impulses or instincts. The culmination of this doctrine is found in Freud's theory of the domination of the sexual impulse. No better corrective of this exaggeration could be found than is contained in this work, and in particular in the section on sex instruction. The author has something also to say on mental tests. Testers are, he says, losing their mental balance, and are confusing administrative with psychological procedure, so that devices invented to make easy the rapid marking of large numbers of answers have been erected into laws of the working of the mind. Hence we are offered tests in which the examinee no longer answers questions, but merely selects a stupid answer forced on him by the examiner. The book is excellently written, and free from the vice of many recent books on psychology, for its language can be understood by an educated person. There is an excellent bibliography.

This is a book both for study and reference. Despite its excellent form it is issued at a remarkably low price for present-day publications.

### PATHOLOGICAL HISTOLOGY.

THE second edition<sup>2</sup> of MAX BORST's book on pathological histology differs in no essential particulars from the first. Certain figures regarded as unsatisfactory have been replaced, and new illustrations inserted; and a separate chapter has been devoted to the organs of internal secretion. Otherwise the book remains the same, and is to be regarded, as the author expressly states, not as a textbook of pathological histology, but as embodying the subject-matter of a course of practical work such as is generally included in the medical curriculum. It, in fact, represents the actual course of pathological histology, apart from microscopical technique, which the author has found to be the best, after an experience in teaching extending over

twenty-five years; it should, therefore, be of interest to other teachers as affording a means of comparison with their own methods. Its most noticeable feature is the arrangement of the subject-matter on an anatomical basis; the several organs and systems are dealt with in order, commencing with the circulatory system and blood, followed by the respiratory system, and so on through the digestive, urinary, sexual, nervous, and locomotor systems to the skin and ductless glands. There is no section dealing with general pathology, the author considering that, if a careful selection of preparations is made, the facts of general pathology as regards any given lesion, tubercle for instance, may be satisfactorily deduced from the recurring examples of the disease that are met with as the organs are passed in review. An exception is made with regard to neoplasms. These are dealt with on a pathological basis and are described at considerable length; they occupy, in fact, nearly one-fourth of the volume. The section constitutes a valuable statement in concise form of our present knowledge of tumours, their relation to other tissue enlargements, such as hypertrophies, and the principles of the classification of neoplasms. The volume presents a tolerably complete course of pathological histology, but the author is careful to point out, in a short introduction, that the student will do well to regard it as no more than a ground-work for a deeper study. The student may succeed in obtaining a knowledge of the changes from the normal which are revealed by the microscope; but this is of little use without the faculty of correct interpretation, which is perhaps to some extent a special gift of nature, somewhat analogous to the so-called clinical instinct, and in any case is only to be acquired by long experience.

### EUGENICS.

EUGENICS, whether we use this term of classical derivation, or think in the form of common speech and speak of "breed," is of interest to everyone. As citizens we like the look of clean-limbed, well set up, well bred youngsters: they are a promise for the future, which we elders have tried to do something to make better. As doctors we are doubly interested, for nothing pleases the man whose business is so often with the sick and infirm as the contemplation of the wholesome and robust. We, like the prophet Samuel, look with pleasure on the youthful David, "for he was ruddy and of a fair countenance." Dub it love of breed, whether in man or beast, or eugenics as applied to man only, we all want it. The problem is how to get it, how to make sure of it. There can be no doubt that mankind has got it in the past, slowly, gropingly, and perhaps unconsciously; he had, through untold centuries, advanced on the great days of Greece from the scarcely human to the fully sentient human being. He had become a real personality, and some would aver to-day with more personality than his frail flesh can always support. How he has done it he scarcely knows. His breeding methods with the beasts of the field have been conscious, he has acquired a body of tradition founded on long experience, and the eye of modern science seeks to learn from what he has accomplished and seeks to ascertain the effect of the new conditions of highly organized civilization upon the prospects for weal or woe of man's body and mind. What has the future in store when man's fertility is conditioned by these new circumstances?

Major LEONARD DARWIN, in his book *The Need for Eugenic Reform*,<sup>3</sup> discusses this matter in his erudite way. It is a masterly exposition of the subject, and the book will command much study and thought. He leads the reader through easy stages from physical science based upon evolution, through the laws of inheritance and the effects of environment, to population problems. He considers our population is now probably too great. Thereupon comes the consideration of racial poisons, such as alcoholism and syphilis; the inheritance of acquired characteristics and the effects of natural selection are discussed, and the lessons of the breeding farm and the tendencies of individual and mass selection

<sup>1</sup> *Educational Psychology: Its Problems and Methods*. By Charles Fox, M.A. London: Kegan Paul, Trench, Trubner and Co., Ltd. 1926. (Demy 8vo, pp. xiii + 380. 10s. 6d. net.)

<sup>2</sup> *Pathologische Histologie*. Von Dr. Max Borst. 2. Auflage. Leipzig: F. C. W. Vogel. 1926. (Sup. roy. 8vo, pp. xiii + 435; 275 figures. M.43; bound, M.52.)

<sup>3</sup> *The Need for Eugenic Reform*. By Leonard Darwin. London: John Murray. 1926. (Demy 8vo, pp. xvii + 529. 12s. net.)

are set out. A consideration of the problems of the feeble-minded and the habitual criminal, of insanity and genius, are discussed, followed by chapters dealing with the practical and immediate subjects of family allowances, income tax, and social legislation. Finally, he relates these factors with the higher ideals of mankind, and concludes that there is no necessary antagonism between religion and science. In studying this work the reader, certainly the medical reader will not be treading wholly unfamiliar ground, for much of it will be in his mind from the reading or hearing of Major Darwin's lectures; but the book presents the opportunity of taking in the whole of his teaching in a connected study, and it is one not to be missed.

#### LENGTHENING THE MORTAL COIL.

DR. SERGE VORONOFF is a most entertaining writer. His method displays quiet, almost apologetic enthusiasm in advocating his views. The argument seems so simple and straightforward, the evidence so irrefutable, and yet the results are so marvellous that the author appears to feel that some sort of apology is due to the reader. In his *Etude sur la Vieillesse et la Rajeunissement par la Greffe\** Dr. Voronoff recalls first of all to our memory the immortality of unicellular animals which multiply by fission. Who has ever seen the corpse of an infusorium? In the higher animals most cells are mortal; but the sexual cells are immortal, and have eternal life. Yet even the mortal cells do not die a natural death; death which quietly extinguishes the flame of a life of 100 or 150 years' duration is not the enemy. It is against disease, with its concomitants old age and senility, that we must strive. The enfeeblement of the body in old age is due to the atrophy of the specialized cells in each organ, and to the increase of connective tissue. If we can retard this process of enfeeblement we shall not, perhaps, retard natural, physiologic death; but we shall retard accidental death, of which we all die.

Can the cells of an aged organism be rejuvenated? The maintenance of the activities of the cells depends upon the hormones poured into the blood by various glands. In old age this function of all the glands, although doubtless enfeebled, remains, with the single exception of the genital gland. Old age sets in contemporaneously with the cessation of the internal secretion of the genital gland. Dr. Voronoff based his experiments upon the supposition that if the genital glands continued to pour their hormones into the system of the elderly, senility should certainly be retarded. As corroborative evidence he quotes the opinion of a veterinary surgeon on the comparative longevity of a stallion and a gelding, and makes some observations on the physical appearance of eunuchs.

So far, of course, Dr. Voronoff has only been following the line of thought of Brown-Séquard in 1869. Unfortunately, the author points out, Brown-Séquard brought bad technique into the service of a good idea, with the result that he did disservice to the idea itself. Similarly those who attempted to graft testicles under the skin, in the muscles, or on the peritoneum failed to obtain good results. The grafted organ necrosed or was rapidly absorbed. When he began his researches there was, says Dr. Voronoff, absolutely no method of ensuring the survival of the implanted organ in any of the large mammals or in man. The method evolved by Dr. Voronoff was to implant freshly cut slices of young testicle on to the tunica vaginalis of the extinct organ of the aged animal. The proceeding was easy in the case of rams and goats; a young ram or goat could easily spare a testicle for his ancient relative. It was a different matter with human beings. It will always be difficult, says Dr. Voronoff, to procure enough human testicles; not because the ablation of one testicle makes any difference—the other will always hypertrophy sufficiently for its purpose—but because the mutilation is forbidden by law. Voluntary consent is not enough. At Nice use was made of the testicle of a young man who died of an accident; but, as Dr. Voronoff remarks naively, such

opportunities are rare, and, if one counted on them, occasions for the practice of the operation would be exceptional. In the face of these difficulties Dr. Voronoff had recourse to monkeys; and the rest of his book describes his methods for the simultaneous operation on monkeys and men, and the results he has obtained. There is also a chapter on the grafting of ovaries and the rejuvenation of women. In this Dr. Voronoff displays unexpected restraint. He states that, of course, the best place to plant the chimpanzee's ovary would be in the spot assigned by nature to the woman's ovaries. But he decided not to do this. In the first place, he did not aim at the ovulation of the grafts. In fact, if he had implanted monkey's ovaries on the ovaries of the woman he would have felt compelled to resect a portion of the Fallopian tubes, although he was not much afraid of pregnancy. Again, many of his patients were fat, and Dr. Voronoff thought that the laparotomy might be somewhat rash. He came to the conclusion that an extraperitoneal method would suffice, so he selected the anterior ends of the labia majora in the region where the fibres of the round ligament lose themselves.

The book is illustrated with fascinating photographs, such as that of an ancient ram, who ought to have been dead in 1918, but was rejuvenated and was still propagating his species in 1923; and those of the issue of "Jacky," and of "Jacky" himself, a dilapidated bull in 1924, who in 1925 was quite capable, apparently, of holding his own against younger rivals. The letters from patients, quoted by Dr. Voronoff, display the differences in point of view in different nationalities. The English doctor lays greatest stress on the improvement in his intellectual activities. Amongst patients of other countries the revival of amatory prowess seems to cause most satisfaction.

#### NOTES ON BOOKS.

In a book with the title "*Kinésie Paradoxale*" des Parkinsoniens," which may be freely translated the "paradoxical activity of the Parkinsonian syndrome," Dr. JARKOWSKI has not only presented an interesting study of this particular phenomenon, but has attempted also to find a solution of the whole problem of the physiology of voluntary movements in general. This "*kinésie paradoxale*" consists in the sudden and unexpected displays of motor activity which may be seen from time to time in patients who are usually quite inert with the classical rigidity of Parkinson's disease. Of this peculiar symptom the author gives many interesting examples, testifying, as indeed the whole book does, to prolonged and careful observations. In a discussion of the explanation of the symptoms of Parkinsonism the conclusion is reached that the essential disability consists in a weakening of desire to perform movements, and the hypothesis is advanced that this is due to a loss or diminution of what the author terms "affecto-motor reactions" or "proto-energy." Voluntary movement is therefore dependent not only on the activity of the ordinary motor systems of the central nervous system (and especially, of course, of the pyramidal tract), but also on the associated participation of these affecto-motor reactions. Those interested in this subject would do well to compare the opinions expressed in this little book with those contained in Dr. Kinnier Wilson's recent Croonian Lectures. Though the views elaborated by Dr. Jarkowski are highly interesting, they must be regarded as speculative, and are hardly likely to receive general acceptance, particularly from British neurologists.

A short monograph on the radiological study of the normal and pathological bladder after the injection of opaque liquids has been published, under the title of *La Cystographie*,\* by Dr. H. BLANC and Dr. M. NÉGRÉ, civil surgeons to the Hôpital Lariboisière, Paris. It is the result of the authors' own experience, and contains some hundred radiological illustrations; the history of cystography is briefly recalled; the technique, both radiological and urological, is then described; and, finally, the conditions observed in the normal and the pathological bladder are recorded. Pictures are taken antero-posteriorly, laterally, and obliquely, and show well the physiology of the normal bladder in men, women, and children. The writers classify their cases into four groups: (1) where cystography is necessary, as in diverticula, tumours, the patency of the ureters, and in fistulae of the bladder; (2) where cystography

\* *Etude sur la Vieillesse et la Rajeunissement par la Greffe*. Par Dr. Serge Voronoff. Paris: G. Doin. 1925. (Med. 8vo, pp. 213; 35 plates. 15 fr.)

"*Kinésie Paradoxale*" des Parkinsoniens. Par Dr. J. Jarkowski. Paris: Masson et Cie. 1925. (Roy. 8vo, pp. 79. Fr. 12.)  
\* *La Cystographie*. Par H. Blanc et M. Négré. Préface de G. Starck. Paris: Masson et Cie. 1925. (Med. 8vo, pp. 190; 108 figures. 6s. 8d.)

is useful, as in malformations of the bladder; (3) where cystography is a matter of curiosity, as in hypertrophy of the prostate; (4) where it can be used as a control post-operatively. Of the numerous opaque fluids mentioned in the text 4 per cent. collargol and sodium bromide are considered the best. This method would seem to find most scope in the detection of diverticula and fistulae of the bladder. Tumours are diagnosed mainly on alterations in the contour of the bladder, and the radiograms show distinguishing points between a papilloma and an epithelioma. The book is interesting and well written, and the plates are excellent. As a means of diagnosis, however, this method is limited to a narrow field, as most of the information it reveals ought to be detected by intelligent use of the cystoscope and ureteric catheter. Where it is impossible to pass this instrument, or where the view inside the bladder is obscured, either by haemorrhage, intolerance of the bladder, or by the size of a tumour, then cystography would seem to hold a definite place in surgery.

Binocular vision is confessedly a very complex problem. Not the least of the difficulty of understanding its mechanism—if such a word may be used—is the complexity of the neuromuscular equipment of the eye, the obliquity of the oculomotor muscles, the functions of the nerves and their nuclei. That there are many misfits in these arrangements is not to be wondered at; patent and latent squints might well be expected. The marvel is that there are so few of them. The study of these defects is fascinating, and he would be a rash man who tried to correct such defects without a wholesome appreciation of their difficulties. Dr. G. C. SAVAGE has given much consideration to these problems, and the results appear in his book *Ophthalmic Neuro-Myology*.<sup>7</sup> He propounds a theoretical scheme of neuro-muscular working, and therefrom has built up his own structure. There are, he says, eight conjugate centres in the cortex by means of which the several movements are effected, and one to effect convergence. Each of these centres is connected with two muscles. Besides there are twelve basal centres, each connected with only one muscle. These basal centres only come into action when there is a tendency to diplopia. The idea is a kind of mnemonic such as all students find of use at times, but the serviceableness of such devices does not render them scientific; so that we must disagree with Dr. Savage when he writes: "If the above hypothesis accounts for every phenomenon connected with the normal and abnormal actions of the ocular muscles, as it seems to do, then it ceases to be a hypothesis and becomes a scientific fact."

We have received the fourth part of *The Best Books*,<sup>8</sup> which represent an attempt to provide a systematic bibliography in all departments of science, art, and literature. The present volume relates to natural science, medicine, arts, trade, literature and philology. A list of the most available books on these subjects is given, with the dates of the first and last editions, and the price, size, and publisher's name in each case. The first part of the series was issued in 1910, and dealt with theology, mythology and folklore, and philosophy. The second part appeared in 1912, and included society, political and social economy, the science of politics, commerce and trade, and education; the third part, which dealt with geography, was published in 1923. The present volume will be of special interest to those concerned with the history of medicine and medical bibliography, as well as with more technical subjects.

A third edition of *Recent Advances in Medicine*,<sup>9</sup> by Drs. BEAUMONT and DODDS, has appeared. Reference was made to the two previous editions in our issues of January 3rd, 1925 (p. 26), and August 22nd, 1925 (p. 348). In spite of the short lapse of time there have been considerable alterations in the book, which is increased in size. An introductory chapter has been added on clinical investigations; a new section has been written on the after-care and treatment of diabetic patients, with tables of graduated diets, and the radiological examination of the gall bladder and the lungs is illustrated by radiographs. Recent work on blood grouping is included, and additions have been made to the descriptions of various pathological procedures.

A new edition has appeared of the second volume (English-Italian) of Mr. ALFRED HOARE'S *Short Italian Dictionary*,<sup>10</sup> in

<sup>7</sup> *Ophthalmic Neuro-Myology*. By G. C. Savage, M.D., LL.D. Second edition. Nashville, Tennessee, U.S.A.: Published by the Author. (5½ x 8, pp. viii + 227, 39 plates, 14 figures. 3 dollars.)

<sup>8</sup> *The Best Books*. By William Sonnenschein. Part IV. Third edition, entirely rewritten. London: G. Routledge and Sons, Ltd. 1926. (8½ x 9½, pp. 1681-2510, 36s. net.)

<sup>9</sup> *Recent Advances in Medicine*. By G. E. Beaumont, M.A., D.M.Oxon., F.R.C.P., D.P.H.Lond., and E. C. Dodds, M.D., B.S., Ph.D., B.Sc.Lond. Third edition. London: J. and A. Churchill. 1926. (5½ x 8½, pp. xiv + 408; 46 figures. 12s. 6d. net.)

<sup>10</sup> *Short Italian Dictionary*. By Alfred Hoare, M.A. Vol. II: English-Italian. New and enlarged edition. London: Cambridge University Press. 1926. (Demy 8vo, pp. vii + 421. 10s. 6d. net.)

which the special attention previously paid to idiomatic phrases has been extended, thereby considerably increasing its value. We note with some interest that, whereas in the previous edition it was found necessary to give an Italian equivalent for "Yorkshire fog," in this present edition "Yorkshire pudding" is also mentioned. A conscientious Italian who wishes to understand the exact significance of such words as "yoicks," "yeclpt," and "yahoo" will find his needs fully met.

## PREPARATIONS AND APPLIANCES.

### An Extensible Abduction Frame.

Mr. R. BERTRAM BLAIR, honorary surgeon to the Hull Royal Infirmary, has designed a simple abduction frame. It was made for him by a carpenter out of strips of wood about 3/10 of an inch thick, and 3 inches wide, but in practice it was found that the strips of wood would be more practicable if they were made 3/4 to 4 inches wide. It was capable of extension from 23 to 30 inches (from sacrum to heel), and was exceedingly useful in the treatment of cases of acute anterior poliomyelitis, or after operation for fixation of the hip before the wound was healed. By increasing the amount of padding on the sacral cross-bar a certain amount of hyperextension of the hip could be obtained.

Mr. Blair finds that if the sacral cross-bar is adjusted high enough above the coccyx there is no difficulty at all, as regards nursing purposes, in keeping the patient immovable on the splint. He can be lifted bodily in the splint in order to change bedclothes. The cross-bar A B is designed to support the sacrum: width 3 inches, length 10½ inches, and is capable of extension by 2 inches, the extension being governed by a slit, screw, and nut, the nut being on the under surface. The two pieces of wood are held together by brass rivets, and can slide along one another when the screw and nut are loosened. The cross-bar E F gives strength and is capable of extension in the same way as A B. This bar governs the amount of abduction, 15 inches extending by 3 inches. Right-angled foot pieces are attached at C and D; the vertical portions cannot be shown in the diagram. The portions of splint wood G and H are capable of extension in the same manner as X Y, to fit along the sides of the trunk from the iliac spines to the axilla. The side pieces of the splint X Y are 23 inches long and are capable of extension by 7 inches. The two strips of wood in each are really in apposition with one another, but are drawn with a space between for clearness. They are fixed by means of brass rivets and a sliding screw and a nut, as are the cross-bars.

### A Belt for Visceroptosis.

Mr. W. A. MEIN, F.R.C.S., M.R.C.P. (Bournemouth) writes to recommend a form of belt which was found most satisfactory in the treatment of a patient with extreme visceroptosis and constant pain in the back, who had unsuccessfully worn various abdominal belts. He states that the belt gives comparative rigidity and comfort without any impairment of the movements of the trunk. The springs are so fashioned that a lift in an upward and backward direction is given to the whole of the front pad. The "angle of the lift" is such that the force passes below the pole of the kidneys, from before, backwards, and upwards, the kidneys being held against the posterior parietes, and not pushed forwards in the direction of least support. The pad at the back is designed to give that feeling of support so essential to the treatment of the condition. He adds that the belt has been made by Messrs. Bridge, Christchurch Road, Bournemouth.

## MOTOR CARS FOR MEDICAL MEN.

### NOVELTIES AND TENDENCIES REVEALED AT THE OLYMPIA SHOW.

By H. MASSAC BUIST.

THE yearly international motor car show, which the Society of Motor Manufacturers and Traders opens to-day (Friday October 22nd), under the patronage of the King, at Olympia, Kensington, will be available daily, Sunday next excepted, until 10 p.m. on Saturday, October 30th.

The general motoring conditions in prospect for the ensuing year, as far as mechanical and trading developments are revealed at this exhibition, were reviewed in these columns last week. It may be added now that 45.6 per cent. only of the makes of cars on the home market are of native origin, 25.4 per cent. being French, 12.7 per cent. American, 7.5 per cent. Italian, and the rest Canadian, Belgian, German, Austrian, Irish, Spanish, or Swiss. Four-cylinder engines are the predominant type, representing 54.6 per cent.; but six-cylinder types have increased greatly in number, constituting 36.6 per cent. There is only one twelve-cylinder engined car—the steel sleeve valve 50/150 h.p. Daimler mentioned last week. But the number of eight-cylinder engined car types has been increased from sixteen to twenty, all the new eight-cylinder engines being single line constructions, the most noteworthy of which is the 35-h.p. Sunbeam. Of the score of types, three only have the cylinders V set in blocks of four.

No fewer than twenty-seven new six-cylinder engined models are introduced, the majority by British constructors, ranging in size between 2 and 3 litre cylinder content. This confirms the tendency disclosed at the Paris show a week previously, where every native manufacturer except three presented a six-cylinder engined car type. Moreover, of that trio, two are known to have "small sixes" on the stocks.

Twelve new four-cylinder engined car types are introduced at Olympia, chiefly in the light car categories. There is only one three-cylinder engined car on the British market, but there are three two-cylinder types, two of them being two-stroke engines.

#### NEW SIX- AND FOUR-CYLINDER ENGINED CAR TYPES.

It is not possible, however, to form a definite idea of what will be the demand in regard to the number of cylinders employed, because we are on the threshold of a motoring year in which the public of moderate means requiring cars of moderate power is being offered for the first time practical six-cylinder engines. It is therefore assured that this coming motor year will witness the conversion of vast numbers of those who already own cars from the four- to the six-cylinder principle for a given power. Moreover, the situation at the moment is partly disguised by the effects of the coal strike, since some manufacturers have stocks of four-cylinder engined cars to-day, as of other types, which should have been disposed of by last July at latest. Therefore they are not exhibiting all that they had planned to display.

For the present it will be enough to say that new style six-cylinder engined cars should be studied on the stands of the following makers: Armstrong-Siddeley, Aster, Austin, Bean, Brocklebank, Daimler, Delage, Donnet-Zedel, Humber, Lagonda, Lea-Francis, Minerva, Oakland, Renault, Rochet-Schneider, Standard, Steyr, Sunbeam, Talbot, Vulcan, and Wolseley—certainly an assorted variety. Among new four-cylinder engined cars the following should be studied: Ansaldo, Citroën, Clukey, De Dion-Bouton, Fiat, Gillett, Humber, Lancia, Overland (Whippet), Riley, Rover, and Singer, some of them from curiosity merely. Medical men do not need two- or three-cylinder engines nowadays. Nor are eight- or twelve-cylinder types yet marketed at prices, and in sizes, suitable for the general practitioner.

#### DETAILS TO BE NOTED.

When making a tour of the show the medical motorist should look at such details as the attachment of the springs on cars, as there are some interesting examples

wherein ordinary bolts and shackles have been replaced by Belflex and such-like compositions that need no lubrication. While "one-shot lubrication" is not available, and in many senses is not desirable, for the kind of car necessary to his purpose, he will find that grease-gun lubrication is being standardized to an increasing extent, which is to his immediate purpose. He will observe also many examples of the pressed steel dash so designed as to carry the petrol tank conveniently, accommodate the instrument board neatly, and constitute a rigid cross-brace for the car frame. At last there is a general tendency towards tidy instrument board schemes as standardized.

In bespoke coachwork, finished in paint and varnish, attention should be drawn to the use of new style aluminium castings. Again, in fabric bodies which are very much in vogue, the problem of the fading of colour schemes other than jet black has led to introducing a new style covered body with fabric-covered upper portion and metal panelled lower portion. By this means the lower part and the bonnet of the car can be painted one colour and will therefore match each other throughout the life of the car. There is a welcome tendency to discard the use of lacings and even of cloth, in the interiors of covered cars, and to upholster seats, panels, and so forth in plain shades of quite soft cowhide, which is as suitable for this purpose as it is unsuitable for open bodies.

#### SIX-CYLINDER ENGINES.

It matters not to the medical man whether six-cylinder engined cars are marketed as such, or as "light sixes"; what he wants to know is what they cost to buy and to run, and what advantage they are to him day and night all the year round.

For a given power or cylinder volume, the fuel bill might be a little more; but it would take a great deal of motoring to make it 40s. a year more with a six-cylinder than with a four-cylinder car. As constructed, however, the lower priced, smaller powered, six-cylinder engined car with developed transmission system, superior suspension, and saving of unnecessary weight in details, has a petrol bill approximately equal if fast speed is not indulged in. But where hills have to be climbed, if the motorist wishes to save time he must spend a trifle more on petrol, though there is no occasion for the tyre bill to be heavier if he uses his brakes with judgement and does not "hunt" the engine. If he is willing to go uphill at the same speed as he would with a sluggish four-cylinder engined car of the same actual power, then his petrol bill with a six will be a trifle lighter. But with a six-cylinder engine he will save both time and nervous strain, which are of the greatest importance to the class of motorists I am addressing here. There is not the same necessity to change speed with a six-cylinder as with a four-cylinder engine; in other words, a man with professional problems to solve will not also drain his energies by concentrating on physical tasks when journeying from one patient to another.

#### POINTS ABOUT NEW CHASSIS TYPES.

At this show the medical man may therefore be advised to examine the £18 tax, 2,230 c.c.m., overhead valve, six-cylinder engined, £345, five-seat Standard car, that has been produced with all-weather equipment and, of course, four-wheel brakes. He will see that, though the taxation rating is a few pounds more than he might wish to pay, nevertheless the cost price for a car of this performance is so much below expectations that he will enjoy several years of use before the extra amount of money he must spend in tax will bring up the cost of the car to the limit he had in mind for this class of performance and service. Further, the general belief in the House of Commons is that our present taxation, on the principle of rating engines, will be abolished next year in favour of a fuel tax. This is not an expression of my personal opinion, but merely an incidental record of the present political atmosphere.

This Standard car follows the characteristic practice of the firm, providing ample accommodation and great strength as well as entirely original body construction. The new six-

cylinder engine is rated at 18/36-h.p. Certainly the general lay-out will interest the medical man. For those for whom this is too ambitious, Standard devotes the rest of its enterprise to concentrating on the 14/28-h.p. £275 overhead valve four-cylinder engined car which it introduced at the last show. The performance of this car is remarkable, eclipsing anything Standard has done before. Improved bodywork is available on all types, the developments including increased headroom, a higher windscreen, higher side windows, the extensive use of metal in place of wood in the construction of the body frames and doors, the standardizing of automatic windscreen wipers, and the provision of a special scheme of finishing that renders each body largely immune from the ills to which paint and varnish treatments are subject.

#### CONTRASTED EXAMPLES.

Reverting to six-cylinder engine practice, in another direction we find remarkable enterprise by Armstrong-Siddeley, whose chief novelties are a "long" 18-h.p. model and a "short" 18-h.p. model, the latter being a 20-h.p. R.A.C. rating, 2,872 c.c.m., six-cylinder overhead valve engined machine capable of 65 m.p.h. on top gear, and listed as a Taunton tourer complete at £450, the weight being 30½ cwt. This is therefore another type of six-cylinder engined car, perhaps more ambitious, which nevertheless comes within the class which some medical men require. But this world-famous engineering house, that built Sir Alan Cobham's engines for his flight to Australia and back, introduces other lower-priced propositions, as in the 14-h.p. four-cylinder overhead valve engined chassis at £230, which is available as a Sandown tourer complete at £360, and as a Broadway four-door saloon at £15 more only, the latter having particularly smart lines. Armstrong-Siddeley's 1927 range of cars is very comprehensive, alike in variety of designs, in scale of prices, and in engine ratings. I have merely drawn attention to one or two leading features.

Humber, the pioneer of the cheap four-cylinder water-cooled engined car more than a score of years ago, whose post-war production has been concerned almost entirely with four-cylinder cars, nevertheless finds an insistent demand for a six-cylinder engined type. It meets that by bringing forward, after a long period of trial, a nominal 20/55-h.p. 3,075 c.c.m. overhead inlet and side exhaust valve engined £21 tax car with four-wheel brakes, a range of speed from 5 to 60 m.p.h. on top gear, a 10 ft. 10½ in. wheelbase, a track suitable for overseas service, with general constructional principles characteristic of the firm, including Perrot type four-wheel brakes with semi-servo shoes which are enclosed in weatherproof covers, at a chassis price of £570, or the five-seater complete at £725. Humber is one of the relatively few firms that use front-wheel brakes in association with the transmission brake, a compensating device being fitted between the two. The firm also introduces an entirely new 14/40-h.p. 2,050 c.c.m. four-cylinder overhead inlet and side exhaust valve engined, £460, four-door, five-seat tourer, and a two- or three-seat three-quarter coupé with dickey at £575. Special attention has been devoted to designing this new middle-size engined car to function smoothly and to do a large proportion of its work on the direct drive.

#### IN THE MIDDLE RANGE.

Lagonda supplements the £13 tax, 14/60-h.p., four-cylinder, overhead valve engined chassis introduced last year by bringing forward now a £16 tax, 16/65-h.p., overhead valve, six-cylinder engined chassis with a right-hand controlled four-speed gear-box, a single dry plate clutch, a spiral bevel driven back axle, and six internal expanding brakes employed on the four-wheel principle. A stripped chassis is shown as well as another surmounted by a saloon *de luze* body with partition, and seating two persons in front; three are accommodated on the rear and two on occasional seats. The standard type saloon, not shown, costs £795, the chassis with tyres being listed at £570. The engine has forced feed lubrication. Detachable wire wheels with Dunlop tyres are standardized on a 55 in. track. A grease-gun is used for lubricating the chassis.

Ansaldo, an Italian firm known in this country for its six-cylinder engined practice, may be said to be working also

in the opposite direction, in that it now supplements that enterprise by introducing a new four-cylinder, 1,325 c.c.m. engined, 9 ft. wheelbase, 4 ft. 7 in. track chassis with a fabric universal joint between the engine and the three-speed gear-box, the open propeller shaft having two metal universal joints. The design shows that unnecessary cost has been eliminated without sacrifice of quality. The somewhat unusual practice of mounting the engine and the gear-box on a pair of heavy steel tubes attached to the cross-frame members, while it simplifies assembly, also reduces the time necessary for taking out the units when repairs are required. An overhead camshaft is employed. The forward suspension is unusual in that a transverse spring is used in front, the two main leaves having rolled eyes. In place of attachment to the axle by means of a shackle, a T-member is used with the stem sliding in a cylindrical boring in the axle and butting against a coil spring. A leather gaiter protects the slide from wind and dust. Anchorage to the axle is by means of a U-shaped member of circular section, the two ends of which pass through eyes in the actual forging and are secured by a nut. The loop is anchored to a cross-frame member. The three other Ansaldo models are being continued with practically no change.

#### MORE FLEXIBLE FOUR-CYLINDER PRACTICE.

While few medical men will have any use for the chief Alvis novelty, a 12/50-h.p. sports saloon capable of a speed of 70 m.p.h., the standard four-cylinder engined chassis has great attraction because of the unusual flexibility of the power unit, the roadworthiness of the chassis, and the sturdiness of the construction. This is a type which the firm has developed consistently during a period of years; it is now made only with overhead valve engines. The detail modifications introduced for 1927 in the standard chassis are all sensible and progressive; thus, for instance, a spherical bearing mounting is used for the cross-shaft operating the clutch. A lower gear ratio is furnished to the steering-box to enable low-pressure tyres to be used with ease. Longer wear is assured by the provision of wider brake shoes. A cross-tube, the downward end of which is mounted on spherical bearings to ensure that its movement shall be free of any binding that might be caused by frame whip, is now employed for stiffening.

The nominal 15-h.p. four-cylinder engined Triumph car of 2,169 c.c.m. content aims at all-round good road performance in association with economical running, the four-wheel brakes being hydraulically operated. The five-seat all-weather touring car is listed complete, at £395, the upholstery being in serviceable antique finished real leather. The five-seat four-door saloon shown is listed at £100 more, the upholstery being in enamelled brown furniture hide. The lines of the body are smarter this year.

Apart from the retention of established types, De Dion-Bouton enterprise for 1927 takes two main directions. Very substantial reductions have been made in the cost of all models, amounting in some cases to £190. Yet all chassis have been improved in detail, none now lacking four-wheel brakes, a four-speed gear-box, and cantilever rear springs. These models are supplemented by a new 12/26-h.p. type and by a 20-h.p. type, the former being a side-valve engined machine, with Ricardo pattern detachable cylinder heads, which, for the rest, practically follows the firm's well proved constructional practice. Detachable wire wheels are standardized with large tyres, and the radiator is high enough to give a level line from its cap along the saddle of the bonnet to the high waistline. The standard four-door six-seater is listed at £375 only, the four- or five-seat *de luze* torpedo with wire wheels, or with wood wheels at option, at £425, the three- or five-seat *de luze* torpedo at the same price, the three- or five-seat *de luze* three-quarter coupé at £495, and a four- or five-seat *de luze* four-door saloon at the same price.

#### MORRIS'S IMPROVED SUSPENSION.

Probably the medical man will agree with the man in the street that the new range of Morris prices—the number of models available are too numerous to mention here—is amazingly attractive. But he is not likely to agree that the flat radiator is the most important mechanical improvement made in the chassis. On the contrary, the medical

man will appreciate that the change from three-quarter to half-elliptic rear suspension is a very much more material development, because it vastly improves alike the road-worthiness and the riding qualities of the car. Valuable, too, is the introduction of a pressed steel dash, affording a rigid cross-brace to the chassis and providing a convenient means for carrying the petrol tank (now increased to seven gallons capacity), as well as forming a mounting for the new instrument board, which is a really practical improvement, all the dials being grouped neatly in a central oval flanked by cubby-holes for parcels on either side. More conveniently controlled and better brakes are furnished this year. The adjustments provided for the steering rake and for the clutch and brake pedals will be appreciated; also the better system of controlling the ignition and the carburetter. All these details can be studied conveniently by the exhibition of developed Morris-Cowley and Morris-Oxford 1927 types.

Few novelties are likely to interest medical men, especially those working overseas, more than the latest Morris development shown in stripped chassis form. This is a 2,513.28 c.cm., side valve, four-cylinder engined 15.9-h.p. R.A.C. rating, four-wheel-braked chassis with Dunlop reinforced tyres, and semi-elliptic springs fore and aft, retailing at the provisional price of £245, the open four/five-seater with four doors, completely equipped, costing £325. The complete car weighs 26 cwt., and is capable of a high rate of speed because it has a gear-box with four speeds forward in association with a dry single-plate clutch. The three-quarter floating-type back axle has an overhead worm drive. All the brake-cam operating spindles are carried above the axle in a position where they are not liable to damage on rough roads. This car has a minimum ground clearance of 10½ in., a track of 56 in., and a wheelbase of 9 ft. 6 in.

All Morris coachwork types have been improved considerably by the provision of a higher waistline, deeper and more comfortable seating, and greater leg room. Wide doors are fitted to both the Morris-Cowley four-seater and the saloon types.

As it is impossible to show all the Morris products in the limited space on the stand at Olympia, a special exhibition is taking place during the show period at the Acton premises of Messrs. Stewart and Arden, within easy reach of Olympia by omnibus, every Morris-Cowley and Morris-Oxford chassis type and body type being on view there.

#### TEMPTING PRICES.

No firm in the British industry catering for the motorist of limited means but considerable ambition has gone ahead in the last year as has Clyno of Wolverhampton. Now it offers the two-seater nominal 11-h.p. type with front-wheel brakes, bulb horn, and windscreen, among other additional equipment, at £160 complete, which is £10 less than the cost of a car of this type last season without those accessories. This policy applies also to the four-seater, which has been reduced in cost £17 10s. and has additional equipment, including a windscreen wiper, four-wheel brakes, and a hood envelope. The same remark applies to the higher powered Clyno, which is now an ex-13-h.p. rater, being re-listed in developed form as a 12/28-h.p. machine, every example of which has the firm's system of front-wheel brakes and complete equipment, though each developed type is listed at a lower price than last year: for instance, £40 less in the case of the four-seater 12/28-h.p. type, now priced at £220 complete; and so on. The improved four-door saloon sells at £250 complete.

I referred last week to the 850 c.cm., overhead camshaft operated, overhead valve, four-cylinder engined Singer "Junior," introduced at £148 10s. as a four-seater to supplement the firm's two other models, the four-cylinder engined one of which is now renamed simply the "Senior" type. The six-cylinder engined model is styled the "Six" type. The "Senior" is presented this year with improved coachwork, the details embracing wide, roomy bodies and pneumatic upholstery covered in real leather. The equipment is complete. Four-wheel brakes are standardized on all these models, the four-seater costing £220, the two-seater the same price, and the saloon £40 more. Certainly the six-cylinder Singer, which was introduced

last year, is offered at a very competitive price—namely, £325 for a four-seater touring car complete, and £25 more for the saloon.

The exhibit by Gordon England, long known as specialists in Austin cars, is particularly interesting this year by reason of the proved practicability of its wholly original three-point design of body scheme, to which extensive reference was made in these columns on its introduction last year. It differs altogether from the flexible fabric type in that it is built and mounted to accommodate variations in chassis form. These bodies, which are neither heavy nor unduly expensive, may now be studied in detail and variety.

With a radiator that is a reproduction on a lesser scale of the six-cylinder engined Waverley, this firm introduces a nominal 7-h.p. £100 car with a four-speed gear-box, four-wheel brakes, and a horizontally opposed, water-cooled, two-cylinder engine with side valves, the rating being 7-h.p. The detachable wire type wheels are shod with balloon tyres. Electric lighting is standardized. The body is designed to be large enough for two adults and two children, and is equipped with a hood and a windscreen.

For the ensuing season Bayliss-Thomas offer two chassis, both with overhead valve four-cylinder engines and gear-boxes having three speeds forward; the £10 tax 1,247 c.cm. engined type being listed as a four-seater complete at £225, and the £12 tax 1,496 c.cm. engined model as a four-seater complete at £240 and as a saloon, complete, at £325.

#### POINTS ABOUT ACCESSORIES.

With the facilities provided by the enlarged building at Olympia the industry concerned with the production of accessories for motor vehicles presents a collective exhibit almost bewildering in its quantity and variety. Therefore a mere hint of a few phases of interest can be mentioned here. Thus, apart from its exhibit in the carriage section of various cars with Mann, Egerton and Company's bodies, this firm shows in the accessory section, at Stand 348, an ingenious car-washing outfit, an electrical air compressor and tank, a pressure cleansing tank, a paint-spraying pistol, a breakdown equipment, a car overhauling plant and tools, and a petrol consumption test tank which enables any owner to make an accurate record of the fuel consumption over a given route. The Autocar's "miles per gallon tests" are undertaken with these tanks, which are quite small and give visible reading at any moment.

Again, at Stand 424 A. W. Gamage, Ltd., show an ingenious ashtray, a series of radiator cosies, some attractive cushions, and a wide range of driving mirrors and motor horns. This firm also shows for women motorists rubber heel protectors designed to obviate damage to the most delicate shoe when driving, and which are, nevertheless, quickly slipped into place.

No accessories are subject to more rapid developments than sparking-plugs, owing to the necessity of making them withstand greater heat in proportion as standard engine efficiency is raised year by year. Under this head Lodge (Stand 447) shows a new sparking-plug; this is the latest form of the well known C3 type that is fitted to a large number of prominent British cars this year; it is packed in a new container. Plugs for all other purposes are also shown by the firm.

The latest types of Zenith carburetters are shown on Stand 505, including a new plate type filter that forms an excellent adjunct to the carburetter, non-corrosive bronze rings being employed.

In regard to motor fuel, there is an interesting exhibit by the British Petroleum Company, an all-British concern with refineries at Llandarcy in South Wales and at Grange, mouth in Scotland, employing 20,000 British workers. "BP" spirit for cars is displayed at Stand No. 219 by the suppliers of the fuel for the machine that won the Light Aeroplane Contest at Lympne. The Anglo-American Oil Company, marketers of Pratt spirit, were the first to realize the importance of the guarantee label which they now feature at Stand 270. Many types of petrol pumps, lubricating oil cabinets, and the "depth-o-meter" gauge for recording the contents of underground tanks are shown; also swing arms for use with pumps.

# British Medical Journal.

SATURDAY, OCTOBER 23RD, 1926.

## THE DEBT OF MEDICINE TO THE EXPERIMENTAL METHOD.

"The debt of medicine to the experimental method of Harvey" was the title of the very thoughtful and illuminating oration delivered by Sir John Rose Bradford on St. Luke's Day before the Royal College of Physicians of London. The occasion is always interesting, for though there have been more than two hundred Harveian Orations since the death of Harvey, the audience is always curious to hear how the orator will deal with his subject, while it is confident that he will succeed in showing it in a new light, or at least with new illustrations. Of late years, at any rate, these hopes have not been falsified. The present occasion, moreover, is remarkable because the Harveian Orator of the year is also the newly elected President of the College—a rare pluralism, due in this instance to the fact that Sir John Rose Bradford was appointed Harveian Orator for this year some eighteen months ago by his predecessor, Sir Humphry Rolleston.

The aspect of his subject chosen by the orator is very important, and it is complementary to that chosen two years ago by Sir Archibald Garrod, when he delivered the Harveian Oration on "The debt of science to medicine," which might well be re-read after that of this year. The earlier orator pointed out that the debt of science to medicine was overwhelming, in the sense that nearly all the pioneers of scientific discovery after the awakening from the long sleep of the Dark and Middle Ages were physicians. The very term "physic" suggests the fact that for a long time the physician was the only scholar who studied physics as compared with metaphysics, and included in his studies all the natural science of his time. Even astronomy owed something to medicine, and at one time no physician was well equipped who was not able to cast a horoscope and estimate the influences of the planets on his patients and his therapeutic measures. We tacitly acknowledge this to-day when we speak of influenza, a disease long supposed to be due to stellar influence. Yet ever since that renaissance of learning there has been—as a former lay President of the Royal Society acknowledged at a Harveian banquet—an indisposition to admit freely that medicine is a science in itself. Until late years it may be said to have included physiology and pathology, and if those children of medicine have grown too big to be tied to the maternal apron-strings, yet, as we wrote in a leading article a couple of years ago, clinical medicine is not only the mother of the sciences, but itself one of them. Who will deny that the observations and the conclusions of Thomas Sydenham, whose tercentenary was celebrated in the same number of the JOURNAL (November 15th, 1924), were as truly scientific as the experiments of Harvey or of any contemporary man of science?

Medicine and the other branches of natural science cannot do without one another, for, as Huxley said, "It is a peculiarity of the physical sciences that they are independent in proportion as they are imperfect;

and it is only as they advance that the bonds which unite them become apparent." There is, then, little room for doubt as to the relation of medicine to natural science in the past. What is that relation to-day, and what is it to be in the future? Sir John Rose Bradford said truly that the most valuable benefaction the College of Physicians has ever received is Harvey's exhortation to search and study out the secrets of nature by way of experiment, coupled with the example afforded by his own life's work.

Will such experiments be impossible without the abandonment of the practice of medicine as we know it, and is the advance of the allied sciences so great, or likely to be so great, that in future Medicine, the former mistress of her ancillary sciences, shall herself become their servant, only fit to carry out the directions given her by her former subordinates? If it is to be for the benefit of science and of the patient to whom that science must be applied, then must Medicine yield her pride of place; but we take it that the President of the Royal College of Physicians is far from thinking that this abdication is justified now or likely to become necessary in the future, heavy though the debt may be which he has recorded in his oration. He also showed how great a part clinical observation has taken in furnishing evidence on which fruitful deductions have been made. But, as Lord Moulton—quoted by the orator—has said, progress is slow and uncertain when observation alone is relied upon, whereas by experiment answers are at once obtained from Nature to questions properly put. Though he cannot make direct experiments, the observant clinician is sometimes able to watch the course of events in which Nature herself performs the experiment, and the reaction of the organism to injury or infection furnishes the answer to his inquiry. It was thus that Hughlings Jackson worked out the connexion between voluntary muscular movements and the cerebral cortex, the existence of which was afterwards confirmed in more accurate detail by physiological experiment on the lower animals. These researches form an excellent example of the interdependence of clinical and laboratory methods. The results obtained by experiments on other animals will always need checking by clinical observations in health and disease. Perhaps no department of medicine owes more to experimental physiology than neurology, which has profited enormously by researches carried on in the laboratory; by these knowledge of the mechanisms involved in the production and control of muscular action has been wonderfully increased of late years, and if our means of cure have not increased *pari passu*, there is no cause to lose hope, but rather to look forward to still more knowledge, which may perhaps come from unexpected quarters.

In an oration commemorating the author of *De Motu Cordis* it was most fitting that much attention should be paid to observations and experiments concerning the heart in health and disease, and to this subject the orator devoted a good deal of his time. We are told by Harvey himself that the problem of the circulation baffled him for so long, despite many experiments, that he was tempted to give it up in despair. In like manner, questions connected with sounds of the diseased heart and its behaviour under pathological conditions have led to great differences of opinion and puzzled many skilled observers. This state of things was, if not completely remedied, at least greatly improved by the work of inquirers who, as was pointed out in the oration, were in search of truth for its sake alone, and not with any thought of

assisting clinical medicine. The beautifully simple and convincing experiments of Romanes on the jelly-fish and of Gaskell on the skate's heart laid the foundations of knowledge recently acquired as to the phenomena of the action of the human heart muscle. Much of this work was done with very simple apparatus, but the explanation of fibrillation in the human auricle, long known to physiologists on the laboratory table, we owe to the more elaborate electrical instruments employed later, which, though not often needed for clinical purposes, have been successful in establishing the fact of the existence of morbid conditions which can now be recognized without their aid.

Sir John Rose Bradford has well set before us the debt which medicine owes to science, and his conclusion that by the use of Harvey's methods we may still "claim that medicine has a scientific status as a branch of natural knowledge" must be considered as amply justified.

### MEDICAL PROBLEMS OF WEST AFRICA.

THE report of Mr. Ormsby-Gore, Parliamentary Under Secretary for the Colonies, on his visit to West Africa,<sup>1</sup> is, as he explains in his introductory remarks, a somewhat tentative contribution by an outside observer to the study of a whole series of problems. Unlike the report of the East African Commission, it is a purely personal document, binding neither of his companions on the tour, and while it is submitted to the Secretary of State for consideration and examination in consultation with the West African Governments, its primary aim is to give the people of Great Britain and other parts of the Empire some general picture of conditions on the West Coast as seen during what was admittedly a very brief tour. In such a document it would be unreasonable to expect any detailed discussion of the problems of tropical medicine, and, in fact, no such discussion is attempted. The chapter devoted to public health does, however, give an interesting and suggestive review of the advance already made and of the conditions which must determine future progress. The information it contains fully justifies the contention "that the field for investigation in tropical disease in West Africa is still great, and that the need for active preventive and curative measures is pressing." We may add that if the administrative difficulties presented by the organization of the West African Medical Staff and the direction of its efforts over so wide a field can be dealt with in the sane and sympathetic spirit which underlies the whole of this report, the further contention that "this Service provides a career which may well prove attractive to the young and enthusiastic medical man" may become equally well founded. Meanwhile, certain observations included in the report must serve as a partial explanation for the fact that, notwithstanding the relatively high rate of pay and the superior opportunities it offers for research, the Service has not recently proved as attractive as might have been expected. Among such observations three in particular are significant. One suggests the existence of "an unduly rigid and centralized system of control" in connexion with the development of the hospital system; the second speaks of the failure to appreciate the possibilities of the leave regulations expressly designed to allow of adaptation to individual requirements; and the third notes that only now is the medical staff, depleted during the war period, approaching its full strength.

<sup>1</sup> Cmd. 2744. H.M. Stationery Office. 1926. Price 3s. 6d. net.

Recognizing climatic conditions as the determining factor in British West African policy, Mr. Ormsby-Gore gives considerable space to a discussion of the divergent views of those who have experienced conditions both in West Africa and in other parts of the tropics, and expresses the general opinion that "the man who goes to West Africa has to face greater disadvantages than in many other tropical countries, besides those inherent in life in any tropical climate." On the other hand, he traces the reputation of the West Coast as "the white man's grave" to historical conditions which no longer obtain. He illustrates the effect of increasing knowledge of the causes of tropical diseases and the principles of tropical hygiene, and the consequent adoption of antimalarial measures and improved sanitation, by the fall in the death rate of European officials from 20.6 per 1,000 in 1903 to 12.8 per 1,000 in 1924, and the corresponding decline in the invalidity rate for the same period—from 65.1 per 1,000 to 21.7 per 1,000. As regards the health of the European community, adequate provision for leave periods, suitable housing accommodation, including an adequate supply of married quarters, improved water supply, and, wherever possible, electric power for light and fans, and improved drainage, more especially in the capitals, are indicated as urgently necessary, and practical suggestions are offered for the improvement of existing conditions. Due emphasis is laid on the fact that the West African Colonies are in a state of transition between the old conception of the public health functions of the Government as confined to the provision of a "garrison" medical service for attendance on officials, and the newer acceptance of responsibility for the promotion of the health of the whole community, both native and European, and on the contribution towards this change of outlook made by the Ross-Manson discoveries in preventive medicine.

According to the particulars contained in the report, the total strength of the West African Medical Staff is at present some 240 officers. These, with the help of a few women medical officers, engaged more particularly with child welfare, and a "fairly large" number of West African medical officers, are responsible for giving effect to this new conception in four colonies, geographically isolated and with widely differing needs and characteristics, with a total native population of some 23 millions scattered over an area of nearly half a million square miles. Little wonder is it that in his summary review of the main diseases prevalent in the West African Colonies, Mr. Ormsby-Gore has to lament the difficulty, "in view of the great extent of the country and the shortage of medical staff," of taking any effective measures to combat outbreaks of relapsing fever and cerebro-spinal meningitis which have occurred in the northern provinces of Nigeria since the war; and to regret that a severe outbreak of plague at Sekondi on the Gold Coast in 1923-24 spread inland to Kumasi, and, in the course of the latter year, to Nigeria. Cases are still occurring in Lagos and parts of the Ijebu-Ode province. The number of these cases is, fortunately, small. The review touches upon the work in connexion with trypanosomiasis and the experiments in methods of control of the tsetse fly carried out on the Gold Coast and in Northern Nigeria, where an important conference was held by the Lieutenant-Governor at Kaduna in September, 1925. Sleeping sickness is not, however, so prominent a factor on the West Coast as in the East African dependencies. The commission sent by the Rockefeller Foundation to West Africa to

study yellow fever had not at the time of the tour succeeded in discovering a case of typical yellow fever of the same nature as that which occurs in the West Indies and Central America. The results of the commission's research, as of the work on blackwater fever which is being carried on in Rhodesia, will be awaited with considerable interest as of great importance to West Africa. The problem of malarial control is rightly presented as very largely one of the education of the natives in the elementary laws of hygiene. An interesting contrast is drawn between Southern Nigeria, where venereal infection would seem not to be a principal cause of mortality either directly or indirectly, and the Northern Province, where it is roughly estimated that nearly 50 per cent. of the Hausa population are infected with syphilis or gonorrhoea. The absence of reliable vital statistics in West Africa is noted as a serious handicap to those responsible for the direction of medicine in making the most effective use of the staff and funds at their disposal.

In the discussion of hospital accommodation some very pertinent remarks are made as to the necessity and importance of further development. While due credit must be given to the excellence of the provision already made in the Colonial Hospital at Accra and the extensions under construction at Lagos and Freetown, it is deplorable that it should still be necessary to lay down as essential features not invariably present in existing hospitals that they should be suited to local conditions, properly equipped, and immune from breakdowns in the supply of all necessary drugs and dressings, or to protest that the performance of major operations in the village market-place is hardly a fitting procedure for countries advancing as rapidly as the West African colonies. Much stress is laid upon the need for the expansion of medical services, including hospital services, more especially in Northern Nigeria. The West African Governments already devote to medical and sanitary services from 10 to 15 per cent. of their total expenditure. The problem of the necessary expansion is therefore largely a financial one. For its solution Mr. Ormsby-Gore looks to the establishment of a native subordinate medical service, whose members should have received a good general education, a training as dispensers and dressers, and "such amount of general medical training as to fit them to take emergency measures and to supervise generally the sanitation and public health of a village." The work of these men would be supervised by travelling medical officers, who might have at their disposal small travelling laboratories, and would be available on a summons to any particular area where disease might break out. The suggestion is controversial, but worthy of careful consideration, as, indeed, is the whole report.

#### THE HARVEIAN FESTIVAL IN LONDON.

The Harveian Festival at the Royal College of Physicians of London was celebrated on St. Luke's Day in the usual manner. In the morning the President of the College, together with the censors, attended the church of St. Mary-le-Bow to hear the Sadleir sermon. This was delivered by the rector, Canon Gordon Ponsonby, who mentioned the losses by death during the past year of the Harveian lecturer for 1925, Sir Frederick Mott, and of other well known members of the medical profession, including Sir John Williams and Sir William Leishman. The sermon was based on the text "God is love," and the preacher referred at considerable length to the posthumous address

of Dr. J. G. Adami to the Church Congress on the relation of science to religion. The lesson was from the seventh chapter of the Book of Wisdom, which spoke of the power and spirit of the Wisdom of God moving through all human realities and events. Dr. Adami had similarly realized the utter darkness which would have existed but for the light of revelation, and had concluded his address with a strong expression of the growing intensity of his belief in the power and love of God. In the afternoon the Harveian Oration, on the debt of medicine to the experimental method of Harvey, was delivered by Sir John Rose Bradford; it is printed in full in the opening pages of this issue, and is commented on at page 741. After the oration the President presented the Bissett Hawkins medal to Dr. Ambrose Thomas Stanton, principal medical officer of the Federated Malay States and director of the Government Laboratories at Kuala Lumpur. This medal is awarded triennially to a British medical practitioner who has performed work in sanitary science or the promotion of public health which, in the opinion of the College, deserves special recognition. In the evening a dinner was held in the College, in accordance with custom and the injunction of Harvey; it was attended by a large number of Fellows, and many distinguished guests were entertained, including the Earl of Balfour, K.G., O.M., Lord President of the Council and chairman of the Medical Research Council; the Archbishop of Wales; Sir Ernest Rutherford, O.M., President of the Royal Society; Sir Berkeley Moynihan, Bt., President of the Royal College of Surgeons; Sir Frank Dicksee, President of the Royal Academy; Viscount Hambleden and Sir Frederick Fry, K.C.V.O., members of the Council of King Edward's Hospital Fund for London; the Attorney-General (Sir Douglas Hogg), Mr. Justice A. C. Clauson, Sir George Thane, Emeritus Professor of Anatomy in University College, and the Rev. S. G. Ponsonby, vicar of St. Mary-le-Bow. The toast of the guests, given by the President, was acknowledged by Lord Balfour in a happy speech, and by the Archbishop of Wales. The senior censor, Dr. H. Morley Fletcher, in proposing the health of the Harveian Orator, recalled that the oration had been delivered by the President on four previous occasions—by Dr. Josias Clerk in 1708, the year of his election to be President; by Dr. Charles Goodall, who succeeded him, in the following year; by Sir Henry Halford in 1835, in the fifteenth year of his presidency; and by Sir James Alderson in 1867, the year of his election. The Harveian orator is appointed by the President in the year preceding the date of the delivery of the oration. After dinner the library was visited, where the Harveian librarian (Dr. Arnold Chaplin) had put on view a number of the incunabula and manuscripts possessed by the College.

#### A RADIOLOGIST LOOKS BACK.

On taking the presidential chair of the Section of Electro-Therapeutics of the Royal Society of Medicine for the first time, Dr. G. B. Batten on October 15th delivered a reminiscent address from the point of view of a general practitioner who has had experience in radiology ever since the  $x$  rays were discovered, and in electrology from a still earlier date. Dr. Batten, who began his  $x$ -ray work in 1897, claimed to be the oldest radiologist still practising in London. Of the many things his long experience had impressed on his mind he mentioned two. One was that the worker was always more important than the machine; in  $x$  rays particularly the advance in technique had gone ahead of the advance in apparatus. The second was that most of the progress had taken place through a succession of booms and slumps. First came the original discovery, with a consequent boom, then a comparative slump, followed by a certain amount of careful research and steady work, resulting in the retention of a really efficient method, the

scrapping of others, and emergence of the method into general recognition and appreciation. From this point of view he discussed the progress of high frequency and diathermy, the x rays, radium and radio-active substances, and light and heat treatment. One value of high frequency which he thought not generally appreciated was in the treatment of haemorrhoids; high-frequency applications were an almost certain palliative and often a cure in this distressing complaint. Diathermy was at present in its period of boom, especially in America, but he hoped that the power of diathermy for evil as well as good would prevent the unskilled worker and the quack from venturing on its exploitation. An urgent need was for a portable diathermy machine, reasonably priced and adapted to British conditions of electrical supply, by which patients could be treated in their own homes. He paid a tribute to the sound work accomplished during nearly thirty years by the Röntgen Society, which had now amalgamated with the British Institute of Radiology, and would doubtless render still greater service. The use of x rays had had its booms and slumps, though they had been less pronounced than those of other agents used in electrotherapeutics. A boom in respect to diagnosis occurred at the beginning, when patients were examined radiologically for all sorts of conditions which it was quite impossible for x rays to reveal. An inevitable boom occurred during the war, when the rays were applied widely for the localization of foreign bodies. Of late years there had been a boom in the x-ray therapy in gynaecological cases. Though the sanguine hopes held out with regard to the Erlangen method had not been fulfilled, the method of dosage with highly penetrating rays was becoming better understood and was entering upon the scientific plane. The public had to be guarded from the unwise use of x rays. It was extraordinary what expectations people entertained. They would come to the consulting room with the question, "I have got a chronic headache; will you give me x rays?" or "My husband's nerves are awful; will x rays do any good?" The progress in x rays, said Dr. Batten, had followed three main lines. in respect to tubes, to coils and transformers, and to photographic materials and accessories. The double-coated films now in use were really wonderfully good. The Potter-Bucky diaphragm also represented a great advance in technique. Methods of protection had rather lagged behind, but the principle of protection near the source had gained ground, and a comparison of the hands of present-day workers with the scarred and maimed hands of those who worked twenty-five years ago was significant. Of one form of x-ray treatment Dr. Batten claimed to be the originator in this country—namely, the treatment of ringworm of the scalp. He successfully treated his first case at the end of 1902. The London County Council began the x-ray treatment of ringworm in 1910, and Dr. Batten showed statistics of the cases treated under the Council's auspices and of the cases cured. One curious feature of these official figures was that for several years the number of cases cured was in excess of the number treated. This meant that cases were recorded as under treatment in one year and as cured in the year following; this should have been rectified in the grand totals, which showed, from 1911 until the middle of 1926, that 53,798 cases had been treated and 53,988 cured! Radium and radio-active substances found their best use combined with or consecutive to x rays, and this not only in malignant but in less serious conditions. Light treatment was now in its period of boom, and manufacturers could not make lamps fast enough. He believed the boom would do more good than harm, but the indiscriminate use of light by the inexpert would do some harm, so that presently there would be a slump, due to disappointment, and this would be the opportunity for a really scientific light therapy to emerge.

## A MALARIAL ADVISORY BOARD.

THE annual report of the Malaria Advisory Board of the Federated Malay States<sup>1</sup> affords abundant evidence that those in authority have no intention of resting on their laurels or allowing conditions to lapse into their previous unhealthy state from relaxation of effort. Four meetings were held during the year, and a number of matters were brought before the Board for consideration. The report shows that this consideration was most thorough, and in no instance was a subject shelved without some definite conclusions being reached. Maintenance of the various health measures is ensured by thorough inspection and the apportioning of responsibility, so that there is always someone to whom those in doubt can apply with a certainty of receiving information and help; the intention is to leave no loophole for the shifting of responsibility. A vaunted new remedy for malaria, known as "Peraerina No. 303," was given a thorough and fair trial, and the conclusions, unhesitatingly expressed, are that it is quite ineffectual and cannot be trusted as a substitute for quinine. Propaganda took the form of circulars in the languages of the people, copies of which are appended to the report, and there is an account of various "shows," where there were exhibits of drainage schemes for malaria prevention, measures for personal prophylaxis, aquaria with larvicidal fish and insects, the destructive powers of which were demonstrated at frequent intervals, thus affording ocular proof of their value; at one of these shows nearly 70,000 persons attended. The list giving the constitution of the Board is sufficient guarantee that the excellent work already performed is to be assiduously followed up, and the record of their doings is evidence that measures are determined upon only after due examination, and that they will be amplified or modified as occasion requires without either waste or stint—a standing example which some other colonies might well ponder, and, after pondering, follow.

## ETHER ANAESTHESIA.

We have received from that distinguished veteran of surgery Dr. W. W. Keen of Philadelphia a copy of the inscription on the "Ether" monument in the public garden adjoining the Common at Boston, Massachusetts. No doubt Dr. Keen was moved to send this record at this time by having in mind the fact that his letter would probably arrive on a day very near to the eightieth anniversary of the demonstration of the efficacy of ether as an anaesthetic in the hospital at Boston on October 16th, 1846; the inscriptions on the four sides are as follows:

## Side I.

"There shall be no more pain."—*Revelation.*

## Side II.

"In gratitude for the relief of human suffering by the inhalation of ether a citizen of Boston has erected this monument."

The gift of Thomas Lee.

## Side III.

"This also cometh forth from the Lord of Hosts which is wonderful in counsel and excellent in wisdom."—*Isaiah.*

## Side IV.

"To commemorate the discovery that the inhalation of ether causes insensibility to pain first proved to the world in the Mass. General Hospital in Boston, October 16th A.D. MDCCCXLVI."

On top of the monument is a statue of the Good Samaritan ministering to the wounded traveller. It will be noticed that the patriotic citizen of Boston who gave the monument, in view of the very heated controversy which had raged around the names of Morton and of Jackson, wisely decided to avoid or perhaps to extinguish the strife by

<sup>1</sup> Federated Malay States. Annual Report of the Malarial Advisory Board for the year 1925.

mentioning no one by name. Not only was the credit of the discovery claimed by these two, but there have not been wanting those who have made claims for other experimenters in the United States. But it is beyond dispute that the operation performed under other anaesthesia in the Massachusetts General Hospital by Dr. John C. Warren on October 16th, 1846, first made known to the world the practical value of ethyl ether as a means of procuring insensibility to pain. On this historical occasion Morton played a conspicuous part. There seemed to be a curse on the pioneers of anaesthesia. Hickman, who first anaesthetized animals with nitrous oxide, could not get opportunities of applying the method in the human subject, and died young and disappointed. Morton died a bankrupt after failing to make a commercial success of ether; and Wells, who first used nitrous oxide in dentistry, and Jackson both became insane. Dr. Crawford W. Long of Georgia, who anticipated them all with ether, did not publish his experiences at the time, and he alone lived on untroubled by ambition as a country general practitioner. There is a monument to Long, on which his use of ether is recorded, at Jefferson, Georgia, and the University of Pennsylvania unveiled a medallion to his honour in 1912. It is difficult to kill any person with an overdose of ether, and small risk was run by the first experimenters with this substance; but Simpson and his friends, who later experimented with chloroform and some other allied substances, stood a very great chance of fatal accident. The reader of the account of Simpson's proceedings must be filled with wonder at the fortunate escapes of the investigators. Perhaps this lucky immunity has something to do with that confidence in the safety of chloroform as a general anaesthetic which prevails on the northern side of the Tweed, although no less an authority than Sir Berkeley Moynihan, in his address delivered to the Medical Society of London on October 11th, expressed his adverse opinion in the following terms: "It is some years since chloroform has been given to any patient of mine; it is far too dangerous a drug."

#### PATHOLOGICAL RESEARCH IN JAPAN.

THE National Research Council of Japan is to be congratulated on the first appearance of its *Transactions in Pathology*.<sup>2</sup> The first fasciculus gives ample evidence that the Council intends to give us of its best both in the subject-matter and in the style of the work. The two long articles comprised in the fasciculus are written in German, and although doubtless every English medical man is well acquainted with that language, we may hope that many of the subsequent contributions will pay us the compliment of appearing in our own tongue. The first article is by Dr. Masugi, and deals with the histology of the bone marrow in diseases of the haemopoietic system. He has studied a large number of cases in which the marrow changes were the result of simple stimulation, and compared them with the changes observed in splenic anaemia, acute and chronic leukaemia, pseudo-leukaemia, chloroma, and lymphadenoma, and has noticed certain significant differences, more especially in regard to the reticulum of the bone marrow. His general conclusions are that in splenic anaemia the hyperplasia of the marrow is of the simple reactive type; that in chronic leukaemia the reticulum exhibits a different and quite characteristic arrangement, and that the same feature is observed in chloroma. He further considers that both the reticular and cell proliferation in chronic leukaemia is

perivascular in origin and not diffuse. In acute leukaemia the changes sometimes resembled those of the chronic form, but in some instances were diffuse. In lymphadenoma, although the proliferation of lymphocytes is always perivascular, the arrangement of the reticulum does not present the characteristic form met with in chronic medullary leukaemia. The second paper, by Dr. Satake, gives an interesting account of the theory of the enteric function of the lymphocytes and the record of an extensive series of experiments conducted by himself with a view to testing the accuracy of Nagayo's theory on that subject. Nagayo considers that the emigration of lymphocytes through the intestinal epithelium into the lumen of the bowel is a biological function of the alimentary tract, and that the agminated and solitary glands are the sites of exit. On this theory the Peyer's patches have not a defensive function, as has been generally supposed, but are, on the contrary, dangerous sites of bacterial invasion. He further considers that the lymphocytes are in some way connected with the metabolism of fat. Satake's experiments tend to confirm Nagayo's theory. He found that the emigration of lymphocytes was most abundant where digestion and absorption are most active—namely, in the small intestine and caecum; it is at its maximum in the duodenum and jejunum, gradually diminishing in the course of the ileum, and exhibiting a sudden increase at the caecum. In fasting animals the emigration steadily decreases up to the time of death. With regard to the influence of different kinds of food, Satake found that the emigration of lymphocytes was most marked in carbohydrate and fatty diets, and that in these, contrary to what occurs in a protein diet, the lymph follicles become hypertrophied. Both papers are of considerable interest, and give good promise that the *Transactions* will be a valuable addition to medical literature.

#### SCARLET FEVER AND MEASLES.

AN important departure from the recognized use of hospitals for infectious diseases has just been made by the Metropolitan Asylums Board on the recommendation of its Infectious Hospitals Committee. It has been decided to abandon the present practice of always admitting scarlet fever in preference to measles; to allocate beds to the two diseases; and to revise periodically the allocation, so that in times of measles prevalence the larger proportion of accommodation shall be allocated to measles. In 1910 the Board decided to receive cases of measles and whooping-cough into its hospitals, but restricted the admissions to the beds available after the claims of scarlet fever and diphtheria had been satisfied. For the future the claims of diphtheria will be considered paramount, owing to the importance of early and efficient treatment and skilled nursing. The type of scarlet fever seen in London during recent years has been so mild that the large majority of the patients would probably recover whatever the conditions under which they were treated. From measles in London, on the other hand, of every million people living during the last fifteen years, 251 have died annually, as against 42 from scarlet fever. Of cases of measles treated in the Board's hospitals the case mortality was 10.6 per cent., whereas for scarlet fever it was only 1.5 per cent. To provide accommodation for the 80,000 to 100,000 cases of measles which probably occur in London annually is out of the question, but the Board considers that a substantial increase in the present accommodation might be made by so modifying the present scheme of allocation as to give to measles a considerable proportion of the beds now allocated to the less important disease—namely, scarlet fever. These changes have been agreed to by representatives of the Ministry of Health, the London County Council, and the

<sup>1</sup> Those interested in the history of ether may refer to "The Jubilee of Anaesthesia," *BRITISH MEDICAL JOURNAL*, October 17th, 1896, p. 1135. "Henry Hill Hickman: a Forgotten Pioneer of Anaesthesia," *ibid.*, April 13th, 1912, p. 843. For Long, see *Anaesthesia*, by J. T. Gwathmey, second edition, London, Churchill, 1925.

<sup>2</sup> *Japanese Journal of Medical Sciences. Transactions. V, Pathology.* Vol. I, No. 1. (7½ x 10), pp. 81; illustrated.)

metropolitan borough medical officers of health. When a large proportion of the available accommodation becomes occupied, the selection of cases for admission to hospital will be made by the borough medical officer of health in accordance with the necessities and home conditions of the individual case. The policy adopted by the Metropolitan Asylums Board falls into line with the trend of the report on scarlet fever issued by the Office International d'Hygiène Publique, to which we called attention on October 9th (p. 643). The Infectious Hospitals Committee foresees that departure from the long-established practice of removing to hospital every case of scarlet fever may at first cause some criticism, until the public realizes the pressing reasons for the change and the advantages of the new policy.

#### PREVENTION OF DEATHS FROM CANCER.

THE Yorkshire Council of the British Empire Cancer Campaign has issued, very opportunely, a collection of clinical data on the causation and treatment of cancer, entitled *Notes on Cancer for Medical Men*. The book has been prepared by the Medical and Scientific Committee of the council, of which Sir Berkeley Moynihan is chairman. It is not a record of research work carried on by that committee, but an up-to-date and carefully balanced statement of the present state of knowledge. Such subjects as the increase of the death rate from cancer, family liability, cancer houses, methods of treatment, and the claims of quacks, are dealt with. There are excellent chapters on recent and illuminating investigations into the possibility of producing experimental immunization to cancer by Lumsden, and also on the work of Gye and Barnard. We have only cited these few since they form common topics of conversation in regard to cancer in well read circles. On such occasions any doctor who may be present is expected to be able to answer all and sundry questions with the voice of authority. This the book of the Yorkshire Council will help him to do. We understand that a copy of it will be sent to every registered medical practitioner in Yorkshire, and that a copy may be obtained free of cost on application to the offices of the Yorkshire Council (47, Park Square, Leeds) by any medical man. We anticipate that there will be a considerable demand for the book, for there can be no doubt it will serve a most useful purpose. As is seen from its title, the volume is primarily addressed to medical men, but much of it could be read with advantage by intelligent men and women who are not members of the medical profession. It contains, however, two short sections directly addressed to the public; the first is on the education of the public on cancer, and the second consists of questions and answers about cancer. Copies will be sent to any medical man desiring to distribute them among his patients on application to the above address. We may take this opportunity of calling attention also to another authoritative publication—the "Statement of Facts and Opinions" put out by the conference held last month at Lake Mohonk, New York. It is published in full at page 752, and as it was drawn up by a meeting of some hundred persons specially concerned with the pathology and treatment of cancer it must be regarded as embodying the best present opinion on the subject, and, therefore, as a document of great importance.

#### INTERNATIONAL OPHTHALMOLOGICAL CONGRESS.

At a general meeting of the Convention of English-speaking Ophthalmological Societies held in London in July, 1925, it was resolved: "That this Convention of English-speaking Ophthalmological Societies hereby empowers its president, Mr. E. Treacher Collins, to appoint a standing committee of five, of which he shall be chairman. The duty of this committee shall be to obtain such co-operation as is possible

from representatives appointed by various ophthalmological societies for the promotion of international ophthalmological congresses." It was also resolved that other matters of international ophthalmological interest should be referred to the international committee, when constituted. The committee of five, constituted in accordance with the above resolution, consisted of Mr. E. Treacher Collins, Dr. Edward Jackson, Sir John Herbert Parsons, Dr. G. A. de Schweinitz, and Mr. Leslie Paton. It considers that the time has now come to take further steps to form the larger representative international committee suggested. An invitation has been addressed to an ophthalmological society in every country where such a body was known to exist, and where none could be traced to a leading ophthalmological surgeon. It is desired that each nation should be represented by two delegates nominated by arrangement between the principal ophthalmological societies of the nation, or, in the case where no national ophthalmological society exists, by representative ophthalmologists. The meetings of the committee will be held at the Hague in July, 1927. The standing committee is now ready to receive the names and addresses of the two delegates selected to represent each country, and asks that they may be sent to Mr. Leslie Paton, 29, Harley Street, W.1, so soon as arrangements can be made for their nomination.

#### JOHN BULL.

THE first social evening of the Royal Society of Medicine for this session was held on October 18th, when an unusually large number of Fellows and their friends assembled to meet the new president, Sir James Berry, and Lady Berry. Sir Arthur Keith gave an address on "John Bull: a study in anthropology," which he suggested might be considered as a sequel to his lecture on "Punch as an anthropologist," of which we gave some account on January 26th, 1924. His present intention was to show how caricaturists generally, and Sir Bernard Partridge in particular, had delineated a type of cranial formation which was actually characteristic in some measure of many British subjects, though rarely found in an unmodified condition. The gossamer fancies of Sir Arthur Keith's wit and wisdom were skillfully woven together in his inimitable way to show that the stocky neck and aquiline nose, the brachycephaly, and the chin and forehead development associated with the character John Bull, first described by Dr. John Arbuthnot, though representing an ideal and not an actuality, were nevertheless characteristics of invaders of these shores who came from beyond the Caucasus in the second millennium before Christ. The characters had followed the Mendelian lines of inheritance and were still to be detected, not only by British but also by foreign caricaturists when not in too unfriendly mood. The John Bull type was certainly not Saxon, nor a later introduction into England. The lecture was most warmly appreciated by the large audience.

#### LISTER MEDAL.

THE Lister Medal for distinguished contributions to surgical science, with the honorarium of £500, has been awarded by the Committee of Representatives from the Royal Society, the Royal Colleges of Surgeons of England and Ireland, and the Universities of Edinburgh and Glasgow, to Professor A. F. von Eiselsberg of Vienna. This is the second award of the medal; the first was to Sir William Watson Cheyne. An address is to be given by Professor von Eiselsberg at the Royal College of Surgeons of England, in accordance with the conditions of the trust, on Thursday, July 7th, 1927, at 5 p.m. There will be a reception in the museum from 4 to 5 o'clock before the lecture, and the specimens added to the museum during the year will be on view.

## A MEDICAL REVIEW OF SOVIET RUSSIA.\*

IV.—CHANGE IN TYPE AND INCIDENCE OF  
DISEASE.

BY

W. HORSLEY GANTT, B.Sc., M.D.

(Formerly Chief of the Medical Division of the American Relief  
Administration, Leningrad Unit.)

## PART II.

## MODIFICATIONS IN INTERNAL DISEASES.

**Factors.**—Although the total of diseases increased enormously during the war and famine, some decreased not only relatively but absolutely. The bad conditions acted as therapeutic agents for some derangements, or at least possessed a compensatory value. The etiological factors beginning in 1915 and culminating in 1920-21 were: (1) The psychical strain of the war and revolution—the loss of home, fortune, and friends, and the uncertainty of the future.† (2) The food: (a) starvation, particularly in fats and proteins, and involving all classes; (b) the indigestible and irritating character of the food, such as salt herring during 1918-19, and later mechanical irritants—as oats, millet, and flax; (c) the elimination of all alcoholic beverages until 1922, and the sharp decrease in tea, coffee, and tobacco. (3) The lodgings—the lack of light, warmth, and comfort during the worst years, and the presence of dirt. (4) The physical strain—the necessity for hard manual labour by those not accustomed to it, and the lack of means of locomotion.

It is suggestive therapeutically to see which diseases were affected by these conditions.‡ The following figures are an analysis of about 5,000 cases from the Erisman Hospital, Leningrad.

**Adiposity**, with which 0.75 per cent. of patients entering the hospital were affected in 1914, decreased to 0.37 per cent. in 1917, and completely disappeared in 1918-21.§ Chronic alcoholism fell from 1.5 per cent. of patients in 1914, to 0.75 per cent. in 1916, and in 1919 to 0.001 per cent. Diabetes mellitus was absent entirely during the famine years, and podagra showed a marked decrease. Drug addicts were also absent from the roster in 1920-22.

**Circulatory Diseases.**—With the exception of nephritis nearly all of these showed a marked increase. Arteriosclerosis and hypertension, cardiac neuroses, angina pectoris, myocarditis, and aortic aneurysm were greatly increased. In 1914 disease of the heart and blood vessels constituted 2.7 per cent. of all dispensary patients; in 1918 4.2 per cent. Anaemia and dyspnoea were almost universal and bradycardia was common. These figures indicate that whatever benefit to cardiac disease might have accrued from the lightening of the diet was more than offset by the terrible mental and physical strain of the life of that time. Nephritis did not change its incidence. Emphysema was slightly increased. Raynaud's disease and chilblains were greatly increased.

\* Previous papers on medical and scientific work in Soviet Russia by Dr. Horsley Gantt were published in the *BRITISH MEDICAL JOURNAL* in 1924: I, A Review of Medical Education in Soviet Russia, vol. I, p. 1065; II, Hospitals and Health Conditions in Soviet Russia, vol. I, p. 533; III, Scientific Work, Incidence of disease" was published on August 14th last, p. 303.

† Some idea of the strain under which the Russian was living can be gained from a comparison with the men of the relief organizations. They were in Russia for only one or two years, and usually had the Soviet Government had; there was no overcrowding, and the clothing and calorie intake were sufficient. But even among them there were several deaths from pneumonia and typhus, a good many contrain, and a large number developed neurasthenia.

‡ I am especially indebted to Drs. Lang and M. V. Chernoroussky of the Leningrad Medical Institute, Dr. A. P. Zelheim, and Dr. A. A. information given me personally regarding disease statistics.

§ A certain professor of medicine who was overweight had unsuccessfully run through the gamut of the various treatments for obesity. During 1917-19 he became thinner than a normal person, and fell to about one-half his former weight. He has, however, now regained his 240 lb.

**Gastro-intestinal Diseases.**—Chronic constipation almost entirely disappeared owing to the coarse quality of the food. Haemorrhoids decreased. Most of the catarrhal and inflammatory conditions of the gastro-intestinal tract were greatly decreased (gastritis, chronic intestinal catarrh, chronic colitis, appendicitis). From 1914 to 1917 the incidence of appendicitis cases was nearly constant (2.3 per cent.), but in 1918 it dropped to 0.8 per cent. and in 1919 to 0.01 per cent. Diseases of the bile ducts—cholecystitis and cholelithiasis—decreased gradually from 4.7 per cent. in 1914 to 4 per cent. in 1917, and dropped suddenly to 1 per cent. in 1918 and 0.8 per cent. in 1919. The marked decrease in all these conditions suggests the value of starvation in their treatment, as it seems unlikely that the enforced exercise or the irritating nature of the food could have been so efficacious.

No change was noticed in the incidence of pneumonia, cancer, epilepsy, or endocrinal disease. Frequent ecchymoses were seen on the uvula and tongue from the rough food. Acute enteritis became epidemic. Meteorism and flatulence were generally present. But the most notable increase was in peptic ulcer (see above in the section on surgery) and in abdominal ptoses. The latter were present in 1/4 per cent. of all hospital (Erisman) patients in 1914, but the figure rose to 1 per cent. in 1917, 2 per cent. in 1918, and 5.2 per cent. in 1919. This was attributed to the emaciation and to the nervous and physical strain.

## NEUROLOGICAL AND PSYCHIATRICAL DISEASES.

A description of nervous and mental diseases falls into two periods—that of war, revolution, and acute famine, which lasted until the end of 1922; and the years since 1922.

The events of the first period increased enormously all functional neuroses and psychical diseases. "The nervous strain of war would naturally be expected to produce insanity, mental disturbance, and neurasthenia," and this statement held true for America and Germany as well as for Russia.<sup>2</sup> Sir Humphry Rolleston, formerly a Surgeon Rear-Admiral of the British Navy, stated, however, that this anticipation had not been fully realized in the British Navy (in 1916), where serious mental troubles occurred in less than 1 per cent., and mild neurasthenia in less than 4 per cent.; this he attributes partly to the absence of alcohol.

A more potent cause in Russia even than the war was the revolution. Gssipov points out that, although actually the revolution lasted a short time, the concomitants (poverty, blockade, and famine) persisted much longer.<sup>3</sup> The entries for the psychiatric clinic at the Military Medical Academy, Leningrad, were increased not only for the months following the revolutions (that is, in March and December, 1917, the entries were greater than in the preceding and following months), but they were also increased for the years 1918, 1919, and 1920.<sup>4</sup> Gorovoi-Shaltan shows that in 1911 1 per cent. of the population of Petrograd suffered from mental diseases; in 1918, 4.2 per cent.; in 1919, 4.7 per cent.; and in 1920, 5 per cent.\* The figures for defective and delinquent children mounted to an even greater extent. Judging by the number of cases which entered the asylums, the index of child delinquency in 1910 was 3.6 per cent.; in 1918, 17 per cent.; in 1919, 22 per cent., and in 1920, 27 per cent. In 1920 52 per cent. of these were theft cases, nearly all of which were caused by the extreme hunger of the child.<sup>5</sup>

**Neurasthenia.**—Besides the increase in the serious psychoses the milder forms, such as neurasthenia, were greatly augmented. It has already been mentioned that some diseases, such as gastric and duodenal ulcer, in which nervous conditions seemed to play a part, were remarkably increased. We may inquire into the change in the type of psychoses which occurred during these troubled years.

**Typhus Psychoses.**—Many infectious psychoses resulted

\* The figure 1.9 per cent. given for 1911 does not represent the total number, because the asylums were able to care for only 58 per cent. of these patients. However, with the dying off of all chronic cases and the decrease of the population after 1917, the hospitals could fully satisfy the needs of the population in this respect.

from the typhus epidemic.\* It is worthy of mention that Spirtov, who made a special study of the effect of the typhus on previously existing organic nervous diseases, chiefly general paralysis of the insane, found that in contradiction to the views of Krapelin and others who have worked with malaria and general paralysis, no change was produced by the typhus toxin in general paralysis except for a slight psychic improvement during the acute stage.<sup>6</sup>

**Famine Psychoses.**—The acute shortage of food and other difficult conditions of life caused a temporary psychosis simulating dementia praecox; it cleared up under proper nutrition. Other symptoms resulting from the famine resembled hypothyroidism. Serifimoff states that some starving patients showed symptoms that pointed to an affection of the nucleus ruber or of the corpus striatum.

**Asylums.**—The psychoses of patients who had been already confined to asylums underwent interesting changes. The following account is taken from communications from Serifimoff and Dobrotvorskoy. Until 1917 the inmates were sufficiently fed; during 1917 the feeding was sporadic, and in 1918 when the famine began, the patient often received only 800 calories. The shortage in the asylum rations amounted in 1918 and 1919 to 27 per cent. and 45 per cent. respectively of the normal in carbohydrates; 14 per cent. and 16 per cent. of normal in fats; and 23 per cent. and 22 per cent. of normal in proteins. "This resulted in an almost complete dying off of chronic cases in 1918; the mortality, which in pre-war times was 4 per cent., averaged 21.8 per cent. and in some months exceeded 30 per cent." Serifimoff says it exceeded 42 per cent. in some months, and that although the patients were greatly weakened by the shortage of food, nearly all the deaths were directly caused by acute exhaustion. After 1920 the mortality was not nearly so great. The weight of the men decreased by 24.7 per cent., and that of the women by 21.8 per cent. The percentage of recovering cases decreased, and acute cases became chronic. Mental diseases became more frequent among women than among men. An epidemic of theft spread among the patients, extending even to the most intelligent, who entirely lost all ethical control. States of despondency increased at the expense of mania and exaltation, which became rare. Ossipov and Dobrotvorskoy, who studied the psychoses of the 1905 revolution also, showed that the events of revolution do not develop psychoses *sui generis*, but give a characteristic colouring to existent forms. The patients in their delirium appropriate titles of war commissars, and during the famine those with delirium grandiosum operated with very scanty provisions of food, which seemed large to them on account of the shortage. Money was all forgotten, and only food thought of.

"The usual noises, abuses, and quarrels of the wards ceased; the only moment of animation was that of the distribution of the scanty rations. . . . The whole of the decay, cold, and famine was accepted by the patients as inevitable; life became unusually gloomy even for an asylum; patients took no interest in recreation, and expressed their disapproval of such arrangements during times so hard; they realized that conditions outside were worse, and did not try to escape."<sup>7</sup>

In the treatment of all these conditions nothing new was evolved. The cranio-facial index was introduced by Shalaboonoff, and is claimed to be more accurate than cranial index as a measurement of intellectuality. Lentz showed that in patients dying from starvation the brain loses 8.23 per cent. protein, 11.48 per cent. lipoids, 5.23 per cent. nitrogen, and 2.25 per cent. phosphorus. The grey substance of the brain loses 9.30 per cent. protein,

8.33 per cent. lipoids, 9.54 per cent. nitrogen, and 2.10 per cent. phosphorus.

**Alcoholism.**—Of those nervous diseases which decreased during the famine and war, alcoholic psychoses were the most notable. This was due to the prohibition of the sale of alcoholic drinks, which began in 1914 and continued until 1922. Since 1922 the strength of spirituous beverages has been gradually increased, and in September, 1925, the 40 per cent. vodka (the same as in Tsarist times) was reinstated. The amount to be sold\* in 1926, as announced by the Government, will be more than that for 1924, but less than in 1913. The price of vodka in 1913 was 70 kopeks (20 pence); and in 1926 it was 3 roubles (7 shillings) per litre. The present higher price tends to restrict its use somewhat. Drunkenness was always notoriously popular in Russia with all classes, and the consumption of strong spirits was said to be greater than in any other country. Formerly the peasant spent practically all his earnings on alcohol, and the popularity of vodka does not seem to have diminished greatly at the present. Alcoholic drinks are especially injurious in Russia because the Russian will hardly drink wine or beer or anything except the strongest vodka obtainable, and that undiluted and often without food. The figures for the decrease in alcoholism have been given above. In 1922 it was stated (Dobrotvorskoy and others) that no physician anywhere in Russia had seen delirium tremens, which was formerly common, for six or seven years.<sup>†</sup>

**Morphine and Cocaine.**—Cocaine and morphine addicts were increased until 1920, when effective prohibitive measures were taken. Aronovitch states that cocaineism was notable especially in the youth, and that he saw cases of perforation of the nasal septum as a result of the constant smelling and the anaesthetization of the mucous membrane.

**Suicides.**—Suicides became distinctly rarer during the worse years. According to Professor Lang this was on account of the fewer love affairs in the period when the chief concern was only to obtain food to sustain life. They have greatly increased again. This is attributed by Professor Pavlov to the spread of atheism among all classes. (Personal communication.)

**Children's Neuroses.**—At the sixth Russian Congress of Children's Diseases, held in Moscow in 1925, it was pointed out that all the children of the period 1918-23 showed an unprecedented tendency to neuroses. Though their condition has greatly improved since 1924, one-third of all Russian children, on the authority of Professor Shefgo, are now suffering from some neurotic disturbance. It is noted that neurasthenia begins in much younger children than formerly.

#### PSYCHIATRY AND THE PRESENT LIFE.

This completes the review of the revolutionary and famine periods and brings me to a consideration of the present. These past years exerted an unquestioned deleterious effect on nervous and mental diseases, which remain definitely increased even now. The effect of the present mode of living in Russia cannot, however, be stated so unequivocally, and only a guarded prophecy as to its influence on neuroses and psychoses in the future generation can be made. But at least some of the factors of the present life that seem to be etiological can be pointed out.

**Effects Lasting.**—In the first place, the results of the war and revolutionary period will remain for some time. Although the terrible events of these years are now a matter of history, and Russian life has mended itself, their effects are problems of the present Russia. Dobrotvorskoy says:

"The nervous and psychic tone of the population has suffered, and its restoration to normal will have to take place in future generations. France, with its 'Paris blockade children,' may be mentioned as a parallel. Russia's 'blockade children' are not

\* The manufacture of spirituous liquors is now, as it was in the time of the Tsars, a Government monopoly. In announcing the amount to be manufactured during 1926 the Government is virtually announcing the amount that will be consumed; for it knows that the Russian people will drink all that is available on the market.

† The lack of alcohol favoured the study of dipsomania. Professor Ossipov, from a series of these cases which he had observed before the prohibition of alcohol, concludes that a picture of the attacks coincides with the depressive phase of manic depressive psychosis, differing from it only by the shorter duration. In so classifying it he agrees with Korsakoff, but differs from Krapelin, Gaupp, Roemer, and others, who considered it a kind of psychic epilepsy.

\* Besides the acute delirium, latencies, stereotyped movements, and exaltation connected with the acute stage of the fever, several forms of psychosis followed post-infectious "psychical asthma" (Giliarovskiy), which always had a favourable issue, characterized by despondency, emotionality, inability to fatigue and exhaustion, and certain psychical phenomena (atrophy of the skin and muscles, neuralgia, derangements in walk and speech, increased deep reflexes, sometimes paresis or convulsions), depressive mania, which begins as an exaltation state during the fever, schizophrenia; Korsakoff's disease; amnesia; pseudo-paralysis. Trunovoff concludes that "psychical asthma," amnesia, and Korsakoff's disease are different aspects of the same psychosis, whose form is determined by the constitutional peculiarities of the patient. The symptoms are loss of memory, neuritis, and psychic confusion, which are attributed to the action of the toxin and the derangement of the circulation in the cortex of the brain.

† Apropos of this many Russians have told me that they tried to get put into prison during the famine in order to get the meagre ration of black bread.

confined to one city and they] will be a prolonged reproach to the culture of the West, and prove a lasting misfortune to themselves and the State."

Sir William Osler expressed the same thought when he said that the treatment of neurasthenia should begin with the preceding generation. The truth of this statement is borne out by the great increase of nervous diseases and children's neuroses in 1926, and of anthropological changes (see below). Dr. L. Prozorov of the *Narkomzdrav* told me in January, 1926, that he did not think that insanity was any greater now than before the war, because 30 to 50 per cent. of all insane cases died in 1918-20; that now 5 per cent. of the insane cases were in institutions, against 10 per cent. in 1914; that the number of psycho-neuroses had greatly risen since the war.

**Changes in Method of Living.**—It behoves us now to inquire into the changes that have taken place in the method of living in Russia, and how these may affect psychiatric and neurological diseases. At the outset it can be stated that at the present time, neglecting the famine and war years, the life of the peasant, who constitutes 85 per cent. of the population, has not changed much economically from what it was formerly, though it shows signs of improving; that the life of the industrial classes—a very small percentage—has improved; the life of the middle classes is somewhat worse, though gradually improving; that almost all of the extreme changes (financial, social, etc.) have been suffered by a small class, the intelligentsia and aristocrats, who make up less than 5 per cent. of the total, and that large numbers of these are either abroad or have died. Likewise most of the great reversals in life have taken place in the large cities, which contain a small proportion of the total population of all Russia.

**Recreations.**—Much has been written about the sodden, grey, and colourless life of present Russia. This is certainly one of the most remarkable features of the cities as one enters the Union of Soviet Republics from the Western world. After living among the Russian people for some time, however, I have found that this is more apparent than real, and that it is caused chiefly by the lack of the expenditures of a moneyed and leisured class—a relatively small group—and that the mass of the people, especially the lower strata, still have about the same amount, or even more, of pleasures and recreation than they had formerly.

**Fear.**—A parallel statement might be made of the terrorism and the fear of the secret police (formerly the "Cheka," now the "G.P.U."). It exists as a potent factor for undermining the nervous equilibrium but, for relatively few, and with the masses there is less fear of authority than there was under the Tsar. I was told by an inspector of workers' schools that many of the pupils in those schools had never even heard of the "G.P.U." There is now probably more licence, or personal freedom of a certain kind, or freedom from convention, as one chooses to call it, with the exception of political limitations on freedom of speech, than formerly, and also than in a good many other countries.

**Simplifications.**—Russian life is simplified by the lack of money and of nearly all forms of machinery found in civilized countries except telephones, tramways, and moving pictures.\* America, the country where machines are most common, is also the country where neurasthenia has been exceedingly widespread; and there may be some connexion between the two. A simplification in Russian life has recently taken place through the removal of social pretensions and artificialities, which may have a compensatory value in the cultured classes—who have suffered most—where it is chiefly operative.

**Education.**—Perhaps some methods in the present system of education will exert the greatest influence for good or bad on the nervous constitution of the future generation. Certainly many valuable things are being taught the boys and girls now about personal hygiene and sanitation and physical culture that were neglected under the former régimes, and many more people are being educated than formerly. These facts are mentioned in other papers of

this series. The effects of some of the Marxian principles in the present education are not so clearly beneficial, however, from the standpoint of psychiatry. The new freedom, licence, and responsibility given to youth is even more extreme than the conditions in the United States, and in Russia it has come about overnight, while in America it has been a slow development. The effects of this lack of restraint in the youth, of the official and pedagogical warfare against not only the orthodox moral codes but against all forms of spiritual beliefs, of the rapid spread of atheism among the young over the whole country, of the instillation of class hatred, and of a gross materialism, remain to be seen when the generation in which they are taking root reaches maturity. It can be said in favour of the brutal frankness of the present materialism that it has had the good effect of removing the superstitions and fantasies which abounded in old Russia. The moral life in Russia seems to be on a plane that would delight the Freudians. On the other hand, we have the testimony of the eminent physiologist I. P. Pavlov, an opponent of Freudism, who stated in a public lecture that from the physiological point of view the lack of moral restraint taught the youth in Russia is building up a nation of neurotics.\*

Other characteristics of the Russian life, such as unemployment, etc., will not be discussed here as they are too variable and seem to be temporary.

#### DISEASES OF CHILDREN.

For the general conditions of child life that maintained until 1923 the reader is referred to Dr. L. H. Guest's article "Conditions of child life," in the *BRITISH MEDICAL JOURNAL* of October 20th, 1923 (p. 730). Dr. Guest has described adequately the collection of children into "children's homes" during the period of Communism; the general dangers which have beset child life in Soviet Russia, some of the present problems before the Government in dealing with children, and lines along which the Soviet Department of Public Health is making progress in this field.

#### Infectious Diseases.

Most children were immune to typhus and relapsing fever. There was no antagonism noted, however, between the ordinary diseases of childhood and these fevers. Both the morbidity and mortality of measles were strikingly increased during 1919 and 1920. The mortality for this disease in the hospitals of Leningrad was then 30 to 50 per cent., and this agrees with reports from the Volga regions giving a mortality of 40 per cent. (Beeuwkes). The high death rate was thought to be due to the increased susceptibility resulting from the cold and damp and absence of sufficient clothing. By 1922 the frequency and mortality had nearly returned to normal. Scarletina and diphtheria showed no increase until 1922; there was an increase in the complications (30 per cent. of nephritis with scarlatina instead of the normal 15 per cent., and 50 per cent. of laryngeal diphtheria). The general mortality of all children of Leningrad was given officially by the *gubzdrav* (public health department) as 27 per cent. for 1922. The latest figures for the whole of Russia are:

TABLE I.—All Russia: Acute Infectious Diseases.

|                | 1921.        | 1922.        | 1923.        | 1924.        |
|----------------|--------------|--------------|--------------|--------------|
| Scarlatina ... | 381,913 (26) | 75,731 (7.7) | 115,681 (9)  | 201,236 (15) |
| Measles ...    | 467,601 (32) | 132,889 (14) | 124,471 (10) | 327,912 (24) |
| Diphtheria ... | 459,461 (31) | 40,165 (4)   | 52,369 (4)   | 65,620 (5)   |
| Pertussis ...  | 440,915 (30) | 102,348 (11) | 193,33 (18)  | 102,007 (14) |

The figures in parentheses indicate the rate per 10,000 people. The table is taken from *Vestnik Sovremennoi Meditsiny*, June, 1925, No. 6, p. 17 (A. D. Breitner).

\* See *London Times*, May 5th, 1924: "Professor Pavlov stated that the whole of the Russian nation was suffering from an absence of real restraint which induced tendencies to succumb to fantastic suggestions. Neurotic affections had greatly increased recently, caused by the systematic undermining of the instinct of ownership and of the religious instinct. He stated that it was impossible to allow children absolute freedom from restraint during the educational period, as they would be unable to develop for themselves the power to resist emotional impulses, without which human beings become subject to hysteria and other psychoses on the slightest irritation."

\* As one of the Soviet ideals is an age of mechanics and machinery, this condition will probably not remain when they have money to carry out their ideals.

An examination of 2,200 supposedly healthy children by the doctors of the American Relief Administration revealed the following illnesses:

TABLE II.—Results of Examination of 2,200 Children supposed to be Healthy.

| Disease.                     | Percentage of Children Affected. |           | Disease.             | Percentage of Children Affected. |           |
|------------------------------|----------------------------------|-----------|----------------------|----------------------------------|-----------|
|                              | Age 3-7.                         | Age 7-14. |                      | Age 3-7.                         | Age 7-14. |
| Lymphadenitis ...            | 83.0                             | 40.0      | Eczema ...           | 6.2                              | 7.0       |
| Anaemia ...                  | 79.0                             | 68.0      | Scabies ...          | 3.0                              | 6.0       |
| Rachitis ...                 | 58.5                             | 10.0      | Cardiac neurosis ... | 3.0                              | 6.0       |
| Scrofula ...                 | 26.0                             | 11.0      | Scorbutus ...        | 1.0                              | 2.0       |
| Chronic bronchitis ...       | 13.0                             | 15.0      | Otitis media ...     | 4.8                              | 4.0       |
| Tuberculosis (all forms) ... | 3.0                              | 14.0      | Furunculosis ...     | 0.5                              | 2.5       |

The incidence and progressive decrease in mortality of scurvy in the hospitals of Leningrad is given as follows (the figures in parentheses show the mortality): In 1918 there were 752 cases (14 per cent.); in 1919, 839 (9 per cent.); in 1920, 2,065 (5 per cent.); in 1921, 1,301 (4 per cent.); and in 1922, 513 (4½ per cent.). Scurvy and rickets increased greatly in Germany also during and after the war. In Leningrad 80.4 per cent. of the cases of rickets occurred in males.

#### Veneral Disease.

In 1923 educators as well as doctors remarked on the great increase in venereal disease in children. The official organ of the Communist party stated in 1925:

"There has been a remarkable increase in juvenile gonorrhoea in the recent past. Thus in the Metchnikoff Hospital all eighty beds in the skin clinic are filled with children with gonorrhoea, and thirty-five more such cases have just been refused admission on account of lack of space. According to the chief doctor of the hospital there was never before so large a number of children with gonorrhoea. . . . Most of them are young children and come from the children's homes." (*Krasnaya Gazeta*, Leningrad, October 17th, 1925, No. 253, p. 3.)

#### Pirquet System of Feeding.

Our experience in the selection of the 80,000 children which we were feeding in the Leningrad district may be of value to those interested in nutrition. The system devised by Dr. von Pirquet, and used by the American Relief Administration in feeding children in Central Europe, had to be modified in its application to Russian children. The "pelidisi" was introduced as a simple method of determining the state of nutrition of the child. It is an arbitrary number based on a mathematical formula—the relation between the cubic root of the tenfold weight and the sitting height. Below 92 was taken to indicate severe malnutrition, and above 99 as good nutrition. To determine the accuracy of this system we made medical examinations and physical measurements in 2,200 children in Leningrad, taking 100 boys and 100 girls at each year of age from 2 to 13 years inclusive. These children were supposed to be without serious physical ailments, suffering only from the shortage of food.\* We found that 53.3 per cent. of these children were in urgent need of supplementary feeding—36 per cent. being classified as weak and 17.3 per cent. as exhausted. We compared the children with poor nutrition with an equal number of good nutrition (taking 100 boys and 100 girls of each age). Below are our results, as tabulated by Dr. A. Pospelova, a pediatrician of Leningrad, who had charge of this work for the A.R.A.

Most of the poor nutrition was found in the younger children, and in an equal number of boys and girls. From the ages of 11 to 13 there were more girls than boys in a state of poor nutrition. At the age of 12 there was a cessation in development of the child—of increase in height and weight—more marked in the girls than in the boys by an average difference of 5.7 kilograms. The cessa-

\* Classification of the children was based largely on the amount of subcutaneous fat, the tone and tension of the tissues, the development of the muscular system, and the colouring of the skin and mucous membranes ("sacratama" of von Pirquet).

tion of growth acted as a conserving agent, and although the children at 12 had stopped growing, we found as many at the age of 12 in a state of good nutrition as at 11. The relation between the circumference of the chest and half the height of the child was also found to differ more from the normal in girls than in boys.

Instead of accepting a single "pelidisi" for children of all ages as had been formerly recommended, we found that a lower "pelidisi" than the following represents malnutrition at the given ages: 97 for children 3 and 4 years old; 96 for children of 5 and 6; 95 for children of 7 and 8; 94 for children of 9 and 10; 93 for age 11; 92 for 12 and 13. "Pelidisi" lower than 91 always means malnutrition, and the younger the child the greater the malnutrition; pelidisi higher than 98 always means good nutrition, and the older the child the better the nutrition which is indicated by this number."

The "pelidisi" system of von Pirquet used intelligently is a simple and easy method of classifying children; used mechanically it may be very misleading. Corrections are necessary not only as to age and sex (girls at 12 and 13 have a greater sitting height than boys of those ages), but also as to nationality, as shown in Russia by the difference between Russians and Tartars.

#### Infantile Mortality.

As a result of the efforts of the Public Health Department to educate mothers, and of its social welfare work, infantile mortality has been markedly reduced in Russia during the past year or two, and is even well below the pre-war level. For example, in 1914 it was 26.5 per cent., and in 1924 only 18 per cent. (Genss).

## WELLCOME HISTORICAL MEDICAL MUSEUM.

### REOPENING CEREMONY.

THE Wellcome Historical Medical Museum (54A, Wigmore Street, London), which has been closed for some months for cleaning and rearrangement, was reopened on the evening of October 14th. Unfortunately, Mr. Henry S. Wellcome, the founder, could not be present; he was detained on a humanitarian mission in America. In his absence, Sir Humphry Rolleston, Bt., and Dr. John D. Comrie acted as hosts, assisted by Dr. C. M. Wenyon and Dr. S. H. Dawkes, of the Wellcome Bureau of Scientific Research, and Mr. L. W. G. Malcolm, conservator of the museum.

Sir HUMPHRY ROLLESTON remarked that the study of medical history was, somewhat paradoxically, a modern development, and its expansion in this country had been largely due to four men—Dr. J. F. Payne, Sir William Osler, Sir Clifford Allbutt, and especially Sir Norman Moore. This research museum showed the advances which had been brought about through the ages in the various departments of medicine, and the evolution of discoveries and inventions of medical interest; it showed also certain of the retrogressive changes, particularly those which characterized the healing art in Europe during the Dark Ages. London was fortunate in having such an institution, and the whole medical profession was under a debt to Mr. Wellcome for his generosity in making available this wealth of historical lore. It would be difficult to describe how much this museum and library, so quietly amassed, would mean to the medicine of the future.

#### The Functions of a Museum.

Sir ARTHUR KEITH followed with an address the general theme of which was that museum-making and history-writing were the same thing. It was Pitt-Rivers, he said, the founder of the anthropological collection of the museum of Oxford, who demonstrated how reliable human history could be built up, bit by bit, in the shelves and show-cases of a museum, and it was he who made the spade an

instrument of exact history. What Pitt-Rivers did for human culture in general, Mr. Wellcome had sought to do for all that appertained to the art and science of healing, and he had got together an assortment of material for the history of medicine such as had never been available for study in any country. The evolution or history of medicine was more difficult to illustrate by museum methods than any other branch of knowledge. The difficulty came in because in the primitive races of mankind the practice of medicine was founded upon an elaborate code of beliefs—the fine-drawn gossamer of savage fancy—and these were too delicate threads for the relatively clumsy fingers of museum curators to touch. On the belief that the human body was the mere husk and the spirit within it the real person the native physician based his treatment of disease, and therefore to give a concrete representation of the beliefs in which medicine began was particularly hard for men like himself who had been trained to accept only what they could see and prove and to suppress all their childish notions. It would have been otherwise with Lewis Carroll, who understood how children reasoned, and therefore could have entered into the hearts of primitive men without effort. The foundations of medicine were laid on leechcraft, witchcraft, and priestcraft. The early physician was the magician and the priest, and unless this fact was grasped the visitor would altogether fail to understand Mr. Wellcome's hall of primitive medicine, for in that hall would be found a wealth of amulets, charms, talismans, mascots, phylacteries, totems, fetishes, divination bowls, effigies, idols, masks, and ceremonial dresses. This was a massed field of therapeutic artillery, the batteries by which ancient physicians sought to banish illness and disease from their patients. The counterparts in Harley Street of the native artillery were the stethoscope, the bismuth meal, the notebook for prescriptions, and a certain professional air. Sir Arthur Keith added that possibly as visitors walked through the hall of primitive medicine and their eye caught again the weird and uncouth implements of native witch doctors, they would view these exhibits as mere flotsam and jetsam from the Dead Sea of medicine which enlightened England had long since swept away. "I should like to think this is so, but when I see, as I sometimes do, mascots on the motor cars of the wealthy, charms and amulets treasured by many people, both rich and poor, ignorant and educated; when I see, as I occasionally do, the quack preferred to the man who has given his life to the study of rational medicine; and when I see learned men call in spirits to explain unusual physical phenomena, then I am not quite so certain that this part of Mr. Wellcome's museum does represent altogether a past state of things. In all of us there still remains more than a trace of primitive man." Sir Arthur concluded with a discussion of the service which a museum could render to medicine, especially in serving the needs of students, and said that Mr. Wellcome had earned the lasting gratitude of all who believed that the safety of civilization lay in the progress and dissemination of knowledge.

Sir FREDERICK KENTON, Director of the British Museum, in proposing a vote of thanks to Sir Humphry Rolleston and Sir Arthur Keith, said that there were two great men in the history of medicine who would have rejoiced to be

there that night—two men separated by more than two hundred years in time, but akin in their wide knowledge and their tastes and interests—namely, Sir Thomas Browne and Sir William Osler. What curious and illuminating reflections this wonderful collection would have stimulated in the mind of Sir Thomas Browne, and in what quaint and beautiful language he would have expressed them.

Sir D'ARCY POWER, in seconding, said that there was still more than a lifetime's work to be done in arranging and describing the present collection, and it was being added to daily.

Mr. W. G. SPENCER, as President of the Section of Medical History in the Royal Society of Medicine, proposed a vote of thanks to the absent founder. He said that the Royal Society of Medicine looked upon this museum as its indispensable ally so far as the history of medicine was concerned.

Dr. JOHN COMRIE, Lecturer on the History of Medicine at Edinburgh University, seconded the vote of thanks, and mentioned that, stimulated by the medals and prizes offered by Mr. Wellcome, over one thousand students had gone through the purely voluntary course in medical history at Edinburgh.

#### Additions to the Collection.

Dr. C. M. WENYON thanked the audience on Mr. Wellcome's behalf, and at the close of the ceremony the visitors were conducted through the halls and galleries, and the various additions to the collection were pointed out. The Lister section has been considerably enlarged, and includes some of the furniture and fittings from Lister's old ward at Glasgow; these were rescued by Mr. Wellcome when the ward was demolished a

HALL OF STATUARY.

(Copyright, Wellcome Historical Medical Museum.)

couple of years ago. In adjacent cases is some of the material actually used by Lister, and there is also shown a collection held on loan from the Glasgow Lister Memorial Committee. The war section has also been enlarged. The two rooms devoted to primitive medicine have been enriched by many fresh curiosities; a fine collection of shrunken heads from South America was pointed out here. In the arrangement of the collections the evolutionary idea has been followed as far as possible: for example, in the representative collection of instruments employed in surgery from the earliest times the history of each instrument may be studied separately. The historical development of dental instruments and prosthesis is also admirably shown; and again the full history of the microscope and of ophthalmological instruments can be traced. The visitor who wants to be transported into the Middle Ages has only to step into the section devoted to the history of alchemy, where he will find an alchemical manufacturing laboratory such as Paracelsus might have used. The pharmaceutical section carries on the idea, and includes a London apothecary's shop of the seventeenth century, as well as representations of Eastern pharmacies. The portraits, the casts and reproductions, the personal relics (of Jenner among others), the rare models in ivory of the human body, the prints, printed books, and incunabula, the objects illustrating curious phases of medicine such as the history of healing by the royal touch, the specimens of ancient drugs and herbs and medicine chests and apparatus, make an exhibition as fascinating to the casual observer as it is valuable to the research student.

## CANCER CONFERENCE IN AMERICA.

THE conference on cancer at Lake Mohonk, New York State, of which we gave some anticipatory particulars in our issue of September 11th (p. 492), was held on September 20th and four following days. Among those present were Sir John Bland-Sutton, F.R.C.S., Mr. W. Sampson Handley, F.R.C.S., surgeon to the Middlesex Hospital, Dr. Archibald Leitch, director of the Cancer Hospital Research Institute, and Dr. J. A. Murray, F.R.S., director of the Imperial Cancer Research Fund. Representatives were also present from Italy, France, Germany, Holland, Belgium, and Switzerland, as well as from the United States of America. Altogether more than a hundred persons attended. The main object of the conference was to ascertain what measures of agreement on the various problems of cancer in which the public are interested could be reached by discussions between pathologists and clinicians of America and European countries.

At the opening meeting on September 20th Dr. H. Canning Taylor, president of the American Society for the Control of Cancer, was in the chair, and the foreign guests were welcomed by Dr. W. H. Welch. The first paper read (on the following day) was by Sir John Bland-Sutton, on the value of co-ordinated effort among surgeons, pathologists, and others for the control of cancer; he was followed by Mr. Sampson Handley, who spoke on cancer education in England; by Dr. Henri Hartmann, director of the anti-cancer centre at the Hôtel-Dieu, Paris, who described the objects and methods of the organized movement against cancer in France; by Dr. Leon Bérard, professor of surgery at Lyons, on the organization and practical working of the centres against cancer in France; and by Dr. T. Marie of Toulouse, on the need for special institutes for the investigation and treatment of cancer. Addresses on the organized movement against cancer in Switzerland, Belgium, and Denmark were given by Professor Charles Dubois, Professor Maisin, and Professor Johannes Fibiger (of Copenhagen) respectively. On the next day (September 22nd) the description of measures taken for the control of cancer in various countries was continued by Dr. Raffaele Bastianelli (Italy), by Professor Ferdinand Blumenthal, and Dr. Robert Bierich, director of the Institute of Cancer Research at Hamburg (Germany), and by Dr. George A. Soper (America). The results of the surgical treatment of cancer of the stomach were then discussed by Dr. D. C. Balfour (Minnesota); the radio-logical treatment of cancer by Dr. Robert B. Greenough (Boston), and the equipment of institutions for the treatment of cancer by radium and x rays by Dr. Claude Regaud, director of the Pasteur Laboratory of the Radium Institute, Paris. Dr. J. C. Bloodgood (Baltimore) read a paper on the value of education in the control of cancer. The next day, September 23rd, discussions were opened on the new theories of the origin of cancer by Dr. Gustav Roussy, director of the Institute for Research and the Treatment of Cancer at Villejuif (near Paris); on the tissue and racial specificities of cancer, by Dr. J. A. Murray (London), and on the practical value of researches into the causes of cancer by Dr. Archibald Leitch. Then followed three papers on statistics: the first by Professor William de Vries, president of the Netherlands Cancer Institute, Amsterdam; the second by Professor H. T. Deelman (Gröningen); and the last by Dr. Louis I. Dublin (New York).

On the last day of the meeting papers were read by Professor Howard Lillenthal (Cornell University Medical School), on the relation of the general practitioner to the cancer problem; by Dr. George H. Senken (New York), on cancer as a specialty; by Mr. Ivy Lee, Adviser in Public Relations, New York, on some principles of publicity; and by Dr. Harry C. Saltzstein (Detroit), on the co-operation of newspapers.

## STATEMENT OF FACTS AND OPINIONS.

At the close of the conference the following statement of facts and opinions was drawn up and issued:

Although the present state of knowledge of cancer is not sufficient to permit of the formulation of such procedures for the suppression of this malady as have been successfully

employed for the control of infectious diseases, there is enough well established fact and sound working opinion concerning the prevention, diagnosis and treatment of cancer to save many lives, if this information is carried properly into effect.

1. The causation of cancer is not completely understood, but it may be accepted that for all practical purposes cancer is not to be looked upon as contagious or infectious.

2. Cancer itself is not hereditary, although a certain predisposition or susceptibility to cancer is apparently transmissible through inheritance. This does not signify that, because one's parent or parents or other members of the family have suffered from cancer, cancer will necessarily appear in other persons of the same or succeeding generation.

3. The control of cancer, so far as this subject can be understood at the present time, depends upon the employment of measures of personal hygiene and certain preventive and curative measures, the success of which depends upon the intelligent co-operation of the patient and physician.

4. Persons who have cancer must apply to competent physicians at a sufficiently early stage in the disease in order to have a fair chance of cure. This applies to all forms of cancer. In some forms early treatment affords the only possibility of cure.

5. Cancer in some parts of the body can be discovered in a very early stage, and if these cases are treated properly the prospect for a permanent cure is good.

6. The cure of cancer depends upon discovering the growth before it has done irreparable injury to a vital part of the body and before it has spread to other parts. Therefore, efforts should be made to improve the methods of diagnosis in these various locations and the treatment of the cancers so discovered.

7. The public must be taught the earliest danger signals of cancer which can be recognized by persons without a special knowledge of the subject, and induced to seek competent medical attention when any of these indications are believed to be present.

8. Practitioners of medicine must keep abreast of the latest advances in the knowledge of cancer in order to diagnose as many as possible of the cases of cancer which come to them.

9. Surgeons and radiologists must make constant progress in the refined methods of technique which are necessary for the diagnosis and proper treatment not only of ordinary cases but of the more obscure and difficult ones.

10. There is much that medical men can do in the prevention of cancer, in the detection of early cases, in the referring of patients to institutions and physicians who can make the proper diagnosis and apply proper treatment, when the physicians themselves are unable to accomplish these results. The more efficient the family doctor is, the more ready he is to share responsibility with a specialist.

11. Dentists can help in the control of cancer by informing themselves about the advances in the knowledge of the causes of cancer, especially with relation to the irritations produced by imperfect teeth and improperly fitting dental plates. They can also help by referring cases of cancer which they discover to physicians skilled in the treatment of cancer in this location. It may be doubted whether all dentists fully realize the help which can be obtained from x-ray photographs in revealing not only the state of the teeth but the condition of the bone surrounding them.

12. Medical students should be instructed in cancer by the aid of actual demonstrations of cancer patients, and this to a sufficient extent to give them a good working knowledge of the subject.

13. The most reliable forms of treatment, and, in fact, the only ones thus far justified by experience and observation, depend upon surgery, radium, and x rays.

14. Emphasis should be placed upon the value of the dissemination of the definite, useful, and practical knowledge about cancer, and this knowledge should not be confused nor hidden by what is merely theoretical and experimental.

15. Efforts toward the control of cancer should be made in two principal directions: (1) the promotion of research in order to increase the existing knowledge of the subject,

and (2) the practical employment of the information which is at hand. Even with our present knowledge many lives could be saved which are sacrificed by unnecessary delay.

#### PROPOSED INTERNATIONAL FEDERATION.

At the conclusion of the meeting Dr. C. Regaud proposed that an international federation should be formed in order to bring about more meetings of the kind and to publish in at least three languages an index and abstracts of all papers on cancer which appeared anywhere in the world. This proposal was referred to the national societies with a recommendation that the plan, or one similar, should be adopted if on further study means could be found to defray the cost of the work.

#### DINNER.

At a dinner in New York, attended by about 250 medical men, Sir John Bland-Sutton declared that the meeting would make medical history. There had been, he said, a complete absence of acrimony, and much work had been accomplished. The zeal which led so many investigators, surgeons and physicians to cross the Atlantic and to come from all parts of the American continent was admirable, and the earnestness displayed at the conference beyond all praise.

Dr. (Wendell) Phillips, President of the American Medical Association, said that the meeting had done much to

stabilize knowledge and would clarify the opinions not only of medical men but of the public. It was better to preach up the right than to preach down the wrong, and the conference had preached the right without making any attack on individuals or institutions.

Dr. Welch said that the great note struck at the conference was the tremendous importance of the cancer question and the appalling problems it presented. The general public and the medical profession must be aroused to the vital importance of efforts to control cancer. However inadequate knowledge might be to-day, it was an obligation of the profession to the general community that every effort should be made to control this scourge. "The community," he continued, "must be taught that all types of cancer are not certainly and inevitably fatal if they are recognized and properly treated at an early stage. The conference had emphasized the importance of research work, the need of further additions to our knowledge on the one hand; and, equally, the necessity of applying our existing information for the saving of human lives and suffering. There was no disease to which larger additions had been made to our knowledge than cancer, but because this knowledge did not reach the public which the profession was most anxious to reach, it seemed trivial. The many papers and discussions would be published, and make a volume which would be an epochal contribution to our knowledge of cancer."

## Canada.

[FROM OUR SPECIAL CORRESPONDENT.]

#### ANNUAL MEETING OF THE CANADIAN MEDICAL ASSOCIATION.

THE Annual Meeting of the Canadian Medical Association for this year has come and gone, leaving behind it a healthy impression of growth and strength in our medical affairs. The attendance at a point even so far west as Victoria, B.C., was excellent. We cannot praise too highly the unwearied efforts of the Vancouver Medical Association to ensure the success of the meeting. They extended a welcome whose warmth was in keeping with the best traditions of the West, strengthened as it was by the natural beauty of Victoria itself. It was the natural thing for any comment on the meeting to begin with some reference to these beauties, and one such reflective observer remarked that he thought many members of the Association will eventually steal back to Victoria "in a quiet way" with the thought "Better fifty years in Victoria than a cycle in the East."

The standard of papers was high, and if there was no outstanding medical discovery to be discussed there was ample evidence of the increasing scope and importance of the Association. Its growth and organization has enabled it to take a more prominent part in the framing of laws affecting the profession. Medical education is being influenced directly and indirectly, and measures for the protection of public health successfully insisted on. As an example of the degree of organization of the medical profession reference may be made to the Province of Ontario, in which there are forty-seven district societies, all keenly active, showing large amounts of money spent upon extension work and post-graduate lecturing. The programme was practically an all-Canadian one, but several visitors contributed papers. Among these were Dr. Moffitt of San Francisco, Dr. Rowntree of Rochester, and Dr. Ritchie Rodger of Hull, England. Dr. Goldschmidt gave an interesting account of conditions in South Africa, and Dr. J. O. Thompson described those existing in China.

There is a value in these annual conventions which is independent of the scientific side of medicine; they foster personal relations among men in all parts of Canada, something which is as much to be desired as it is difficult to encompass on account of the geographical barriers. There are not, we may be thankful to say, among the profession in Canada, anything of the nature of those political differences which are perhaps too much insisted on; but that we do enjoy such harmony is due in no small degree to the careful organization of our annual convention. The meeting for 1927 is to be held in Toronto.

#### INCREASING NUMBER OF MEDICAL STUDENTS.

There are evidences of greatly increased numbers of men entering the profession of medicine in Canada. McGill University, Montreal, has received over 400 applications for admission to its School of Medicine, and this in spite of an increase in fees, which comes into effect this year, and more stringent entrance requirements. Each applicant must bring proof of two years' university study, including courses in physics, biology, and general organic chemistry, and of a grade sufficient to guarantee good work in the university. A considerable proportion of the prospective students are from the United States, most of them being from New York, Massachusetts, and California. There always has been a fair proportion of American students in this medical school. A recent decision of the Faculty, however, limits the number of first year students to one hundred, and this permits the selection of only the most promising among the applicants.

#### PURE MILK BY-LAW IN MONTREAL.

After a long fight a pure milk by-law has been passed by the city of Montreal. This provides for pasteurization of all milk in the city and the inspection of dairy herds; great improvement in the standard of Montreal milk is expected, more particularly among the small dealers. It has been very sensibly pointed out, however, that legislation per se will not be sufficient, and appeals are made to the milk dealers themselves to aid in the work. This is one among the fruits of the work of the Anti-Tuberculosis and Health League, which was formed here two or three years ago. The report of the league shows the establishment of clinics in the English and French sections, with the organization of a large staff of nurses for public health work. They carry out systematic follow-up work among families in which tuberculosis has occurred, and are prompt in sending contacts to the various centres for examination.

#### HEALTH OF THE CITY OF EDMONTON.

The report of the health department of the city of Edmonton for the year 1925, which has just been issued, shows a strikingly low death rate, both among adults and infants. The population of the city is estimated at 65,000; the death rate per thousand is only seven. The infant mortality was 54.8 per thousand births. Correspondingly low death rates from infectious diseases are shown, as also for cancer, tuberculosis, and influenza. There were no deaths from typhoid fever during the twelve months.

## England and Wales.

### SOCIETY OF MEDICAL OFFICERS OF HEALTH.

At the annual general meeting of the Society of Medical Officers of Health, held at the society's office in London on October 15th, Dr. Herbert Jones was elected an honorary fellow in recognition of his conspicuous services to the society. Dr. E. H. Snell was installed as president, and gave an address on health administration, reviewing the origin and growth of this since the time of the Roman occupation, when a system was established for the efficient repair of drains, the proper cleansing of the streets, the supply of good food to the markets, and the suppression of false weights and measures; these activities corresponded very closely with the duties of the modern sanitary inspector. The work of Chadwick during last century had been mainly instrumental in the great advance of the public health in this country, and his efforts had resulted in the passing of the Poor Law Amendment Act in 1834, and the creation of the first factory commission, while his report of the inquiry into the sanitary condition of the labouring population which was published in 1842 has now become classical. The president mentioned the importance of the report of the Royal Sanitary Commission in 1871, and passed on to show how unification of responsibility for sanitary matters in each town and district had been aimed at, but not yet fully achieved. He urged the importance of simplifying and unifying local and central government, and, as an illustration of the confusion still existing, mentioned the case of an important county borough which delegated its powers under the Midwives Act to the watch committee and the police. The knowledge of preventive medicine was hardly sufficiently reflected and utilized in administrative procedures, and the one essential need at present was a strong Government department to simplify the administrative machinery of public health and to bring the practice of preventive medicine into line with its science.

### BRISTOL CRIPPLED CHILDREN.

As was stated in a note on August 14th (p. 320), there has lately been much discussion as to the best means of providing for the needs of tuberculous and crippled children in Bristol and its neighbourhood. The two voluntary bodies, the Crippled Children's Society and the Orthopaedic Hospital, have recently united, and have decided to build a country school hospital as soon as their funds shall be sufficient. They made proposals for uniting with the municipal council in providing such a hospital; these were examined by the Ministry of Health, which reported in favour of a plan by which the voluntary bodies would provide a kind of convalescent home for the patients from the city's proposed new orthopaedic hospital at Frenchay and for other patients. This decision of the Ministry has somewhat hindered the prospects of a union between the voluntary bodies and the municipal authorities. The matter was discussed at a special and largely attended meeting of the Bristol Division, held at the University on October 1st. The subject was introduced by Mr. Hey Groves, who explained the present position of affairs. Several years ago a property had been acquired by the city on its north-east boundary at Frenchay, and although no new building had yet been erected on this site it had been decided by the Health Committee to build a new hospital for surgical tuberculosis there. In the meantime, in addition to the voluntary hospitals, a strongly supported public movement on behalf of crippled children had come into being. It was felt by most people to be very desirable to co-ordinate as far as possible the activities of the public health authority and the voluntary society. The first great obstacle, however, was the fact that in the opinion of most people the Frenchay site was by no means the best that could be procured for the purpose of an open-air school hospital. A site on a hill slope several hundred feet above the sea level, and having a southerly aspect, could probably be obtained beyond the southern boundaries of the city, and at no greater distance from the centre of the city than Frenchay Park. The latter is flat, comparatively low

lying, lies in the valley of the Frome, and being on the north-east of the city gets a great deal of atmospheric pollution by the prevalent south-west wind. After some discussion, it was decided, with only one dissentient, that a memorandum embodying these facts and opinions should be drawn up and sent to the Health Committee and to the Ministry of Health.

### THE NEANDERTHAL RACE.

At the opening meeting of the eighty-eighth session, on October 14th, of the Liverpool Medical Institution, the president, Dr. J. C. M. Given, delivered an inaugural address on the Neanderthal race. He began by passing in survey the geological periods in which mammals and primitive men appeared; the Tertiary period saw the birth of mammals, the tarsoidae represented to-day in the small tarsius found in Borneo. The hominidae and the anthropoid apes both come from a common stock. The latter are first seen in the Oligocene, more abundantly in the Miocene and Pliocene periods, whereas the hominidae have never been found earlier than at the top of the Pliocene, where *Pithecanthropus*, the Java ape-man, is placed. During the Quaternary period the evidence of man, derived from his skeletal remains, handiwork, and tools, becomes plentiful; knowledge of primitive man was largely due to French archaeologists and anthropologists. Dr. Given then described successively the Chellian, the Acheulian, and Mousterian types, and illustrated their cave habitations with lantern slides. It was now believed that mousterian man was contemporaneous with the Neanderthal race. Huxley was among the first to draw attention to the far-reaching importance of the Neanderthal skull and its significance in elucidating the origin of man. The president then described other fossil remains, and dwelt upon the characteristics of the Galilee skull and that recently brought to light in Gibraltar by Miss Garrod. He drew attention to the points of similarity and divergence between these prehistoric finds of aboriginal man and the anthropoid apes, gorilla, chimpanzee and orang-outang, and set forth the morphological characters of these human types with the help of lantern slides. In conclusion he touched upon the cradle of the human race and passed in review the steps by which *Homo sapiens* slowly developed and spread himself over the world, using archaeological and geological facts to support his view. Sir James Barr proposed a warm vote of thanks to the president, who, it was well known, had devoted a great deal of his leisure to the study of geology and archaeology. Dr. Thomas Clarke seconded the proposal, which was carried with prolonged applause. Afterwards Dr. Given entertained the members to refreshments and music. The number of members is now 520, showing a steady increase, and the finances are in a satisfactory state.

### LONDON ASSOCIATION OF THE MEDICAL WOMEN'S FEDERATION.

The opening meeting of the 1926-27 session of the London Association of the Medical Women's Federation was held at the House of the British Medical Association, Tavistock Square, on October 12th. The proceedings opened with the induction of the new president, Miss Elizabeth Bolton, by Dr. Christine Murrell, the retiring president. A vote of thanks was passed to Dr. Murrell for her services during her term of office. Reports were presented from the subcommittee on menstruation and the subcommittee on cancer research, in which certain research work during the past year was described. Miss Bolton's presidential address dealt with some aspects of disease of the caecum, illustrated by clinical records, lantern slides, and pathological specimens, and with particular reference to diagnosis and the results of operative treatment. After discussing carcinoma of the caecum she mentioned some rarer conditions which were often difficult to distinguish from malignant disease. Among these were actinomycosis of the caecum, inflammatory masses associated with chronic appendicitis, fibro-lipomatous polyp of the bowel complicated by torsion of an ovarian fibroma, and chronic appendicitis and cholecystitis associated with ovarian fibroid. The results of operation were uniformly good in the non-malignant cases.

## ST. LUKE'S DAY SERVICES.

The annual festival service of the Guild of St. Luke was held, by kind permission of the Dean, on St. Luke's Eve (October 17th) in Westminster Abbey. It formed part of the evening service of the Abbey. Members of the Guild in academic robes were conducted to their seats in procession, preceded by their banner, immediately before the entrance of the choir and clergy of the Abbey, while a limited number of seats had been reserved for ticket-holders under the lantern. The lesson, Ecclesiasticus xxxviii, 1-14, was read by the Rev. Dr. Kirkland Whittaker, secretary of the Guild, to whose setting was sung the well known hymn for hospitals, "Thou to whom the sick and dying." The lesson was followed by Bach's anthem "Jesu, joy of man's desiring," after which came the sermon, the preacher being the Rev. Canon Sopwith, vicar of Maidstone. Choosing as his text St. Paul's words, "the beloved physician" (Colossians iv, 14), Canon Sopwith drew an inspiring picture of one whose character made him beloved, adding that there must be many such among those who were followers of St. Luke in the profession of medicine. Again headed by their banner, the members of the Guild of St. Luke took part in the procession, during which were sung the hymns, "Hark! the sound of holy voices," and "For all the saints who from their labours rest." At the close of the service the Dean of Westminster read his Guild collect and pronounced the blessing.

The annual medical service at Liverpool was held in the Cathedral on October 17th, when the Bishop of Oxford (Dr. T. B. Strong) preached the sermon to a large congregation which filled the cathedral. The Lord Mayor and Lady Mayoress were present in state, accompanied by other high civic officials. The acting Vice-Chancellor of the University L. R. Wilberforce and Emeritus Professor of Medicine T. R. Glynn headed the procession of medical men and women, who wore academic dress, and the spacious building lent dignity to the moving mass of scarlet robes and university hoods as the procession wended its way from the chapter house to the seats in the chancel. Mr. Goss-Custard was at the organ; the musical portion of the service was beautifully rendered, and the anthem "O, every one that thirsteth" exquisitely sung. The Bishop took as his text Mark xii, 31: "Thou shalt love thy neighbour as thyself." He pointed out that, great as this commandment was, it was second to that of loving God and complementary to it. He emphasized the importance of man's love for man in the problems that had arisen in recent years. While great increases in knowledge had been attained in social and in economic problems that harassed mankind, many of the principles guiding actions which had been considered infallible would require revision if headway was to be made. He alluded to the beneficent relationship between the medical profession and mankind, which was assuredly based on knowledge, and true sympathy based on personal contact. The offertory made on behalf of the Royal Medical Benevolent Fund was taken by medical men, who acted as stewards on this occasion. Dr. J. Ernest Nevins, whose work in connexion with this and previous medical services has been untiring, merits the thanks of his brethren for his organization of the details so essential to the success of the occasion. The offertory amounted to £110 17s., and the honorary treasurer (Dr. Nevins, 32, Prince's Avenue, Liverpool) will gratefully acknowledge any donation from those who were unavoidably prevented from attending.

The Liverpool members of the Guild of St. Luke, SS. Cosmas and Damian, attended a special service in the Pro-Cathedral, Liverpool. Pontifical High Mass was sung by the Right Rev. Dr. Dobson (Bishop of Cynopolis and auxiliary Bishop of Liverpool). The Rev. Fr. Sheppard, M.A., O.S.B., who preached the sermon, said that the theologian had much to learn from the doctor about pathological conditions that might influence or modify the morality of human acts and about medical procedure which might touch upon the sphere of the moral law; and the doctor had much to learn from the theologian about the practical application of moral principles to certain delicate and difficult situations that might arise in the course of medical work.

## CARE OF CRIPPLED AND INVALID CHILDREN.

A joint conference on the care of invalid and crippled children, arranged by the Invalid Children's Aid Association and the Central Committee for the Care of Cripples, is to be held, by permission of the Council, in the Great Hall of the British Medical Association, Tavistock Square, on Thursday and Friday, November 18th and 19th. Mr. Neville Chamberlain, Minister of Health, will give the opening address, at 10.30 a.m., on November 18th. On the morning of the first day, when Lord Islington will be in the chair, papers will be read on the position of the work for crippled and invalid children in the British Empire at the present time, by Mr. R. C. Elmslie, F.R.C.S. (London); on the position in America and the Continent, by Mr. H. Platt, F.R.C.S. (Manchester); and on future developments, by Sir Robert Jones, Bt., Ch.M. In the afternoon, when the Duchess of Atholl, M.P., will preside, the subject will be the preventive side of cripple work; among the introducers will be Mr. Stuart J. Cowell, B.Ch. (Sheffield), who will deal with rickets; Dr. Arbour Stephens (Swansea), who will speak on rheumatism, chorea, and heart disease; and Dame Agnes Hunt of the Shropshire Orthopaedic Hospital, who will deal with tuberculosis. On the morning of the second day the Hon. Sir Arthur Stanley (Chairman of the Joint Council of the Order of St. John of Jerusalem and the British Red Cross Society) will preside at a discussion on unity of effort. The subject will be introduced by Dr. C. E. Tangye (M.O.H. Wiltshire), Mr. G. R. Girdlestone, F.R.C.S. (Wingfield Orthopaedic Hospital, Oxford), and Miss Christine Cox (Birmingham). In the afternoon, when Sir Robert Jones (Chairman of the Central Committee for the Care of the Cripples) will preside, there will be a discussion on the physically defective child. Dr. K. J. Acton-Davis, M.Ch. (consulting surgeon to the London County Council Cripples Schools), will deal with the child in school, and Sir Montagu Burrows, C.I.E. (Chairman of the Wingfield Orthopaedic Hospital), with the child after school age.

Tickets of membership, admitting to all sessions of the conference, price 5s., may be obtained from the honorary secretaries, Mrs. Munro, I.C.A.A., or Mrs. Townsend, C.C.C.C., 117, Piccadilly, W.1, together with all further particulars. The sessions commence at 10.30 and 2.30 on each day. The railway companies in Great Britain have agreed to issue tickets, available from November 17th to 20th, at the ordinary single fare and one-third for the double journey to passengers travelling to attend the conference. The necessary vouchers to obtain the reduced fares can be obtained from the secretaries of the two societies.

## SIR JAMES BARR.

At the quarterly meeting of the Liverpool city justices on October 12th a letter was read from Sir James Barr resigning the position of medical visitor to institutions under the Lunacy and Mental Deficiency Acts. In his letter he expressed regret at the severance of his long association with the magistrates in his official capacity, and said that he had found the duties very congenial, while his relations with the visiting justices and the clerk had been very harmonious. The Lord Mayor expressed regret that Sir James Barr had found it necessary to relinquish the duties which he had conducted to the satisfaction of everybody concerned since 1884, and moved a vote of thanks to Sir James for his valuable services. Dr. R. I. Richardson, J.P., was appointed to the office thus vacated.

## CENTRAL MIDWIVES BOARD.

The Central Midwives Board for England and Wales held a penal session on October 7th, which was followed by an ordinary meeting. Letters were read from the Ministry of Health (a) informing the Board that legislation would be necessary to give effect to its proposal in that midwives who practise as maternity nurses only should be compelled to notify the local supervising authorities, as practising midwives are required to do, under Section 10 of the Midwives Act, 1902; (b) approving the existing rules until December 31st next, making observations on

certain of the new rules submitted by the Board for approval, and suggesting that Rule E.21 (4), dealing with the cases of rise of temperature, should be altered so as to accord with the definition of puerperal pyrexia in Article 9 of the Public Health (Notification of Puerperal Fever and Puerperal Pyrexia) Regulations, 1926. The chairman drafted a reply, which was approved. With reference to an inquiry from the Registrar of the Joint Nursing and Midwives Council for Northern Ireland, the Board agreed that pupil midwives should not be allowed to count cases of Caesarean section as part of their necessary twenty cases. Drs. Andrew Carey McAlister and Everard Williams were approved as lecturers. The question of printing the Midwives Roll in one or two parts was considered, and it was decided, in view of the fact that the last Roll published only contains admissions to the Roll up to September 30th, 1924, and corrections of names and addresses up to March, 1925, that the new edition of the Roll be published in complete form.

## Scotland.

### PHARMACOLOGY IN EDINBURGH.

PROFESSOR ALFRED J. CLARK, successor to the late Professor Cushny in the chair of materia medica in the University of Edinburgh, delivered his inaugural lecture on October 11th, taking as his subject "The present position of pharmacology." Professor Lorrain Smith, dean of the Faculty of Medicine, presided. Professor Clark referred to his predecessor, Professor Cushny, as the acknowledged leader of pharmacology in this country, whose untimely death in the full tide of active work had been an irreparable loss to medical science. Pharmacology, he said, was ever increasing in importance, because almost every year research was providing important new drugs which formed new weapons of accuracy and power in the fight against disease. Many of these, however, if used incorrectly, were highly dangerous. In order to understand the alterations produced by drugs it was necessary to understand the functions of the body, and hence pharmacology was based on physiology. Pharmacology had really commenced in the last half of the nineteenth century, but its greatest triumphs had been in the present century, so that it might be regarded as the newest of the medical sciences. Advances in this subject had been made chiefly along two lines. In the first place, many drugs had been discovered which would kill parasites living in the body, and secondly, drugs produced by the body itself had been exploited. The discovery by Ehrlich of salvarsan had been the most outstanding example of the former type, and Ehrlich had instituted a new method of research by organizing laboratory tests which would indicate whether a drug could produce the desired action, and then had enlisted the help of organic chemists to help to build up a series of compounds according to a definite plan. His research had consisted in the endeavour to construct a new remedy with the desired properties. His method had proved very fruitful, and by it remedies had been found for a number of important tropical diseases; the dye *germanin*, for example, appeared to be an effective cure for sleeping sickness—one of the most important of the diseases that afflicted tropical Africa. While remarkable triumph had attended the search for remedies that would kill animal parasites, the search for remedies that would kill bacteria after they had invaded the body had been less successful. A few isolated successes had been obtained—for instance, the favourable results obtained by Sir Leonard Rogers in using *chaumoggra* oil derivatives in the treatment of leprosy, and in the recent work by Moellgaard, who had produced a gold preparation, *sano-crysin*, which might prove of importance in the treatment of phthisis. It was reasonable to hope that in the future drugs would be found which would kill bacteria living in the body just as in the last fifteen years drugs had been found as remedies against protozoal parasites. It was possible, too, that drugs might ultimately be found which would discriminate between malignant and normal tissues; such a discovery would mean a revolution in medicine. The other important field of advance had been

endocrinology, the study of drugs produced by glands within the body. The complex problem was slowly being solved, and meantime insulin had been discovered. It was significant, the lecturer said, that the most important progress had been made on the border-lines where different medical sciences meet. Thus, the discovery of new internal disinfectants had resulted from the combined efforts of parasitologists and pharmacologists. Similarly, the discovery of endocrine secretions had been due to the collaboration of physiologists and pharmacologists. Pharmacology, therefore, was particularly interested in co-operation between the medical sciences, in which lay its greatest hope for advance.

### THE ROYAL MEDICAL SOCIETY OF EDINBURGH.

The 190th session of the Royal Medical Society of Edinburgh was opened on October 15th by an address from Sir Herbert Waterhouse, F.R.C.S., on the subject of "Some war experiences of a surgeon in Russia." Dr. J. G. McCrie, senior president of the society, presided. The lecturer said that he had been, prior to the bolshevik revolution, surgeon-in-chief of the Anglo-Russian hospitals, being one of a party which set out from this country, consisting of over twenty medical men, forty nurses, and a complement of V.A.D. nurses and orderlies. After mentioning that during the winter months of 1915-16 the expedition had a hospital in Petrograd, he described the conditions in a hospital near the Pripet Marshes. Three great difficulties had been encountered, consisting of flies, lice, and dust which changed quickly into mud. The staff had had little opportunity for sterilization, as water was extremely short; the amount allowed for drinking and washing was a quart a day. These conditions had persisted all the time he was on the Russian front. Food had consisted largely of rye bread, wild cherry jam, and coffee. The hospital had suffered very greatly from German bombs, and during one day over 100 bombs had been dropped within the grounds; though this had had its effect on the patients, nothing amazed him more than the extraordinary vitality of the Russian soldiers. Sir Herbert Waterhouse described a number of cases which had come under his notice and the treatment adopted. He also gave some interesting information about the German espionage system, describing, among other things, the arrest of a woman spy who had invisible writing on her body. In his opinion, the Russian revolution had been due to Rasputin. A vote of thanks to the lecturer was proposed by Sir David Wallace, C.M.G.

### EDINBURGH SCHOOL FOR MENTALLY DEFECTIVE CHILDREN.

An addition recently made by the Edinburgh Education Authority to the special school for mentally defective children at Balfour Place, Leith, was opened on October 13th by Mr. W. W. McKechnie, senior assistant secretary, Scottish Education Department, who said that for some time the authority had felt that the general organization of the mentally defective schools in its area could be improved. There had been too many small groups with twenty or fewer children in each, of all ages and of the most diverse mental attainments. In such small, heterogeneous groups there could be no adequate supervision for vocational training, which was essential for defective children as soon as they were able to derive profit from it. The mentally defective child was not fitted for the lessons of the ordinary school. It needed a special course in which the training of hand and eye was of the greatest importance. The necessary equipment for this was impossible at small centres, and centralization was therefore imperative. The authority's first duty under the Mental Deficiency Act was to ascertain who were mental defectives, and this was even more a social than an educational problem. The special school should be a kind of observation ward for conduct. If defective children were certified as such while at school, they automatically passed into the hands of the parish council at 16. If they were not certified they received no official care after school years and they were apt to sink into the depths of degradation, misery, or crime. Mentally defective girls especially required to be carefully guarded. Special schools were for feeble-minded children, not for those graded as idiots and imbeciles.

for whom something in the nature of an occupation centre was more appropriate. Teachers, doctors, parents, and the authority were all involved in the grave responsibility of ascertaining mental defect, and this could not be shirked without injustice to the child. There was no reason why every defective child should not be classified by the age of 7 or 8, and it was a serious fault of organization on the part of a headmaster to harbour in an ordinary school for more than six or eight months any mentally defective child of more than 8 years of age. There was a great deal of trouble with the parents of defective children, which was increased in inverse proportion to the intelligence of the parent, for no parents were so difficult to convince regarding the defect of their children as those who were themselves a little below par. Many a mother who had made vigorous protests against the transference of her child to a special school had afterwards blessed the day when the transference was made, for the effort to bring some sweetness and light into the lives of these unhappy children was not wasted, but was one of the best things which had happened in the history of education.

#### MENTAL DEFICIENCY AND MENTAL DERANGEMENT.

The first lecture of a Study Circle arranged by the Edinburgh Women Citizens' Association, consisting of six addresses on the problem of mental deficiency, was given on October 12th by Dr. W. M. McAlister, lecturer in psychiatry at the University of Edinburgh. The subject was "Mental deficiency as distinct from mental derangement." The lecturer quoted Dr. Tredgold's definition of mental deficiency as "a state of mental defect from birth or from an early age, due to incomplete cerebral development, in consequence of which the person affected is unable to perform his duties as a member of society in the position in life to which he is born." Mental deficiency was a lifelong condition, which differed from insanity, because the latter seldom made its appearance before puberty, then developed rapidly, and might be traced sometimes to a single experience. The number of recoveries from insanity was greater than the public imagined, and work in a mental hospital was of a most hopeful nature. Dr. McAlister referred appreciatively to the work which had been done by the association in assisting to establish a farm colony in Scotland where mental defectives could exercise such faculties as they possessed while becoming to some extent self-supporting.

## Correspondence.

#### BRITISH EMPIRE CANCER CAMPAIGN.

SIR,—The Medical and Scientific Committee of the Yorkshire Council, British Empire Cancer Campaign, has issued a booklet entitled *Notes on Cancer for Medical Men*.

Copies may be obtained gratis by members of the profession on application by letter or postcard to the office of the Yorkshire Council, British Empire Cancer Campaign, 47, Park Square, Leeds.—I am, etc.,

Leeds, Oct. 13th.

BERKELEY MOYNTIAN,  
Chairman.

\*\* A note on the scope of this book is published at page 746.

#### DISEASE IN SOVIET RUSSIA.

SIR,—Referring to my article, "A medical review of Soviet Russia," in the *BRITISH MEDICAL JOURNAL* for August 14th, 1926, I desire to add a few comments, as apparently I did not make perfectly clear the disease situation as I see it.

In my opinion the main general causes of the increased diseases and epidemics were the great war, the greater civil war (which was unfortunately prolonged by Allied intervention, being, as it was, unsuccessful), the revolutions, and the famine. Russia was previously saturated with inefficiency, and the wars and revolution had left the country prostrate. Then came severe famine for two years, causing swarms of refugees to move helter-skelter across the country, carrying disease and disorder with them. Although the rigid application of Marxian principles and

war communism following the revolution reacted disastrously on the intelligentsia and the city inhabitants, these classes constitute a small percentage of Russians—there are only 12 per cent. of the total population of present Russia living in cities and towns. But disease was in the country and universal, even where Marxian principles could not be enforced so strictly. Therefore I cannot agree that, in the words of one of your contemporaries, the "great disaster" (referring to disease) "was caused solely by the ruthless application of an economic theory," nor do I think that most of the disease can be attributed to bolshevism, but that it was due to an unhappy combination of events in a thoroughly disorganized and inefficient country. Of course, the revolution (including both revolutions) was a precipitating factor, but this brings up the question as to who should bear the responsibility of causing the revolution.

I desire to state the facts as plainly as possible on so important a subject; and after close acquaintance with conditions for several years, the factors which I mention in this letter seem to me, after careful deliberation, to represent the real causes.—I am, etc.,

Leningrad, Oct. 12th.

W. HORSLEY GANTT.

#### NIGELLUS, THE PHYSICIAN OF THE DOMESDAY BOOK.

SIR,—In the *BRITISH MEDICAL JOURNAL* for March 28th, 1925, I gave some details about a clerk-physician, by name Nigellus, who occupies a place in the Domesday survey. It may interest some of your readers if I add some further facts about him.

Nigellus held land in several English counties, those mentioned being Shropshire, Hereford, and Somerset. The Worcestershire Domesday supplies us with the following additional information. The entry is as follows:

"Terra Sancti Guthlaci. In Cilent Hundredo. De Sancto Guthlaco tenet Nigellus Medicus I hidam in Wich. Ibi sunt ix burgenses redditores xxx solidos de salinis et pro omnibus rebus."

Translation: "The land of St. Guthlac. In Cilent Hundred. Nigellus the Physician holds of St. Guthlac one hide in Wich. Here are nine burgesses paying 30 shillings for salt-vats and for all things."

The Domesday Wich is, of course, Droitwich; even at this early date the salt industry at this place was in full swing, and on Nigellus's land were nine burgesses paying 30 shillings for salt-vats and (I suppose) appurtenances.

I do not find it easy to hazard a guess at the hidage of Droitwich from the Domesday survey, as the land is entered on the record under the name of the holder, the invariable rule in this record; and the Domesday tenants in Worcestershire form a goodly number. Nash, in his *History of Worcestershire*, made an attempt to collect the various entries about Wich under one head, but as I read the page he has omitted the King's own holding in domesne; but he gives the following tenants in Wich in Volume I (page 317) and appendix, p. 5, vol. 2.

The palace of Gloucester, 1/2 a hide. The Church of St. Denys, 1 hide, 18 burgesses paying 4/6, and a vat worth 20 pence. The church of St. Peter at Gloucester, 1/2 a hide. That of St. Peter at Westminster, 1 hide, with 4 furnaces. Nigellus, 1 hide, with 9 burgesses. Ralph de Toden, 1 hide. Roger de Laci, 1/2 a hide, with 11 burgesses. Herald, son of Earl Ralph, 1 hide, with 20 burgesses and 7 vats yielding yearly 50 mits of salt. William Fitz Corbucion, 2 hides (Witton) yielding 70 mits of salt. Urse d'Abitot, 1/2 a hide. Hugh l'Asne, one vat yielding 30 mits of salt.

From another page in the same volume I find that the church of Worcester had eight vats worth 100 shillings, and that the church of Coventry had houses and vats in Wich. St. Guthlac was the hermit of Crowland in the Lincolnshire fens. It may be worth while recalling the fact that Nigellus held land in Hereford under the church of St. Guthlac. I believe that the modern conception of the Domesday hide is that it is not so much an area of land in acres as a fiscal unit; in this case the hide in Wich would probably represent a smaller acreage than a purely agricultural holding such as Nigellus's Shropshire manor.

It is a standing joke against our profession that a doctor is much given to ordering his patients to a health resort in which he, the doctor, has some financial interest; and one wonders whether Nigellus exploited the brine

baths at Droitwich to any extent, or if he depended solely on the revenue derived from the salt. A little further on in the same folio of Domesday, under the land of Rāph do Todenī, we get:

"The same Nigellus holds Duncient and Urso of him. In Cresslaw Hundred. Here are 3 hides. In demesne was one carucate, two bordarii, and two herdsman, and there might have been 5 carucates more. It was worth 25/-, but now 10/-. Odo held it formerly of St. Guthlac."

Round, in *Feudal England*, calls this Nigell "Nigell the Physician." If he had the formidable Sheriff of Worcestershire, Urse d'Abetot, as a tenant, I can only say that he had a most unpleasant tenant.—I am, etc.,

London, W.2, Sept. 28th.

R. R. JAMES.

## OBSTETRICAL THEORY AND PRACTICE.

SIR,—Is the theory of obstetrics, so perfect that its teachers are justified in blaming their pupils for the high death rate of motherhood and early infancy? An improved theory is the necessary preliminary to an improved practice, for theory governs practice in any science or art.

What is a normal labour? What is the cause of pain in labour? What are the causes and symptoms of uterine inertia? These are radical questions, and until they have been satisfactorily answered no one may justly blame general practitioners for the present death rate. Let us postpone the study of the fatal accidents of child-bearing, and study child-bearing itself. That the present-day average labour is pathological is sufficiently proved by a consideration of the suffering, the high percentage of still-born and weakly babies, and damaged mothers, associated with it. Three things are necessary to normal motherhood: a normal labour, in a healthy woman, under clean conditions. Listerism and ante-natal care aim at the two latter; but no one knows on what factors a normal labour depends, so that ante-natal care fails to achieve all that it might otherwise do.

My definition of normal labour and my theory of uterine inertia offer good mental tools for the development of obstetric theory and the consequent improvement of practice, in the hands both of the specialist and the general practitioner. I may briefly put them thus: (1) A normal labour is one in which the uterine contractions act thoroughly efficiently, leading in a short time to the spontaneous delivery of a healthy baby, and causing little or no pain or distress to the mother. (2) Pain is the first indication of uterine inertia. It now becomes possible to apply the principles of the late Sir James Mackenzie's *Symptoms and their Interpretation* to the study of labour. I have published two papers,<sup>1</sup> and have devoted a section of my *Clinical Notes and Deductions of a Peripatetic*<sup>2</sup> to the argument and the application, and am still engaged in a study of uterine inertia on these lines.

A science or art based on such a so-called definition of normal labour as our present accepted "definition" (really only a generalized description of an average labour, which actually omits all reference to the most patent fact of average labour—its pain and suffering) can hardly be regarded as having reached its highest development.

Uterine inertia, and not puerperal sepsis, is the central and fundamental problem of obstetrics. The study of end-results can throw but little light on incipient conditions. The present-day principles of obstetric practice have been proved and found insufficient. The general practitioner may be forgiven for thinking that some other principle, or principles, has been neglected because overlooked, rather than that he has failed to apply the principles he has been taught.

Consider the death rate of ectopic gestation (a maternal death rate). Superior skill in treatment and diagnosis on the doctor's part reduces the death rate; but he is responsible for the reduction of the death rate, not for its existence; likewise he is not responsible for the existence of the ordinary maternal death rate. Antisepsis and asepsis have abolished the old-time "puerperal fever" (an accidental infection carried by the accoucheur), but they

have naturally had no effect on other causes of illness and death during maternity.

There is no doubt that the general transfer of midwifery practice from the general practitioner to the specialist would have at least one happy result—the latter would at long last realize that not medical carelessness but medical ignorance (for which the specialist and the teacher are at least as responsible as the general practitioner) is the defect of practice. Good doctors, good nurses, good hospitals, are but palliative at best. A physiological labour is the prime necessity.—I am, etc.,

MARY C. DEGARIS, M.D., B.S.Melb.

Geelong, Victoria,  
Australia, July 24th.

## GOITRE IN CHILDREN.

SIR,—In your issue of October 2nd (p. 614), Dr. Turton says that I have made an error in imputing to him the statement that lime-containing waters are a cause of goitre; his words contained in your issue of September 11th are: "The distribution of goitre in this county [Derbyshire] shows how closely it is related to places situated either on the carboniferous limestone, or on other geological formations, but deriving their water supply from this formation." And, speaking of Melton Mowbray, "that since the introduction of a new water supply of a very calcareous nature it [that is, goitre] has increased."

I therefore gave in my letter of September 25th examples of water supplies of calcareous origin where goitre was almost unknown, or of very slight prevalence, such as Margate. I take it now that it is waters with "suspended matter, probably calcareous," that cause goitre, as stated by Dr. Turton in his letter of October 2nd, and quoted from Sir James Berry's article in the *Lancet*, February 6th, 1926. I would be inclined to agree that such waters may be one of the causes of goitre, particularly if polluted by bacteria or other organisms.

Is it too much to suggest that the question be put to test in some such way as this: to feed rats on (a) water containing sterilized suspended chalk, the water itself being sterilized; (b) sterilized water and sterilized suspended chalk polluted by faecal matter obtained from goitrous animals; (c) sterilized water without chalk and polluted with faecal matter from goitrous animals; (d) sterilized water. Other food to be the same in all cases and cages scrupulously clean.—I am, etc.,

Glossop, Oct. 9th.

E. H. M. MILLIGAN, M.D., D.P.H.

## MINER'S NYSTAGMUS.

SIR,—On October 2nd (p. 615) a letter by Dr. Ingram-Johnson was published which took exception to my statement that "twenty-five years ago the percentage of nystagmus cases at the South Moor Colliery was notoriously high." My statement was based on the authority of a colliery owner's representative; but as some doubt as to the reliability of the statement has been raised, I have consulted two owners' representatives, and to-day one workmen's representative who remembers Dr. Ingram-Johnson well; they all corroborate my statement entirely. The latter tells me that several of the workmen, including himself, at that time begged for oil lamps in place of the electric lamps with which they were provided. The South Moor Colliery then employed only about 300 men; this year it has employed about 800, and it must be remembered that before the Act of 1906 no records were taken of the incidence of the disease, and all who acquired it just worked on as long as it was possible.

I certainly agree with Dr. Ingram-Johnson in regarding the position at work and consequent strain of the external muscles of the eyeball as a very important factor in the causation of the disease. The tremors of the extended hands and of the neck muscles suggest some deep-seated nervous affection, but I am not disposed to accept Dr. Poston's view (October 9th, p. 664) that miner's nystagmus is caused by interference with the vestibular nucleus.

It is important to distinguish between the two forms of nystagmus: (1) the vibratory form, in which the movements have the same to and fro velocity; the rotatory form may

<sup>1</sup> *Medical Journal of Australia*, August 22nd, 1925, and July 3rd, 1926.  
<sup>2</sup> London: Baillière, Tindall and Cox.

be also included in this class; (2) the resilient form, in which a comparatively slow movement occurs in one direction, followed by a rapid jerking movement in the opposite direction, or in some rare cases by a rapid oscillation. This form is well known in some nervous diseases, such as disseminated sclerosis, Friedreich's ataxia, as well as in vestibular nystagmus and Bárány's tests, but it is never seen in miner's nystagmus.—I am, etc.,

Newcastle-on-Tyne, Oct. 13th

A. S. PERCIVAL.

#### "ATOPHAN DERIVATIVES IN RHEUMATISM."

SIR,—In view of the recent correspondence in your columns as to the toxicity of atophan and its derivatives, particulars of the following case may be of interest.

A woman, aged 63, had for several years suffered from rheumatoid arthritis. On the advice of a friend she took atophan tablets (7½ grains) and averaged one tube of twenty tablets a week. She continued this for four and a half or five months. At the end of about three months she commenced vomiting, and this became more severe and frequent up to the time of her death. Her arthritic pains being benefited, and not associating her vomiting with the atophan, she continued this without remission until three weeks before death.

I saw her a week before she died. The vomiting had become increasingly severe. On palpation she complained of a certain amount of pain over her gall-bladder region; the pulse was slightly raised, the temperature normal. The urine contained a trace of albumin. About three days later she became jaundiced; two days later stuporose; then passed into coma and died.

I was allowed to examine the liver *post mortem* and found this extremely shrunken and small. A section cut by Dr. Gibson of Oxford showed yellow atrophy and a complete absence of normal liver tissue. To my finger the pylorus, and head of the pancreas, appeared normal. The gall bladder and bile ducts contained no stones. There was no previous history of sickness or other gastric disturbances.

Treatment by venesection and the administration of sodium bicarbonate in quantity by all routes had no effect on the course of the disease.—I am, etc.,

C. J. L. WELLS, M.B., B.Ch.Oxon.

Banbury, Oct. 8th.

#### APPENDICITIS AND VEGETARIANISM.

SIR,—For many years past I have had the opportunity of seeing a large number of vegetarian patients, and appendicitis is certainly not an unknown disease amongst them. Only during the last few months I have had a girl under my care whose brother was taken home from school, was transferred to a hospital, was operated on, and died within a week. The sister shortly afterwards developed similar symptoms and was admitted to hospital under my care, and was treated partly by fasting, partly by restricted dieting, partly by severe restriction of all fluids, and partly by the internal use of olive and castor oil, with extremely satisfactory results. Both these patients were life vegetarians, and their parents had been so for years also.

So far, however, I have never lost a patient suffering from appendicitis, nor have I ever yet found it necessary to operate upon one.

In my personal investigations among the villagers of India and Northern Africa, and among the peasants of Liguria and the West Indies, I came to the conclusion that people who ate little meat and who lived upon the simpler foods which prevented constipation were less liable to appendicitis than those who ate a considerable amount of meat and who more or less habitually found it necessary to take aperients.

If it is true that our modern and more meaty dietary is responsible for the increase in the prevalence of this disease there must be a sound scientific reason for it. May I suggest the reason? In carnivorous animals the intestine is shortened, so that by the time the faeces resulting from flesh food have reached the preliminary putrefactive stage they are ejected from the body. Nature has taught the

carnivora that these faeces, even when excreted, are dangerous, and therefore carnivorous animals either make holes for, or scratch dirt over, their defaecated masses. In man the intestine is much longer, and owing to this not a few eminent surgeons have called the lower bowel "the sewage gut," and have advised its removal.

The alternative, from the point of view of scientific hygiene, appears therefore to be, either to live like the carnivora—and amputate the lower bowel—or live like the ancestral anthropoid from whom we derived our alimentary canal, and retain it!

It is, I think, generally admitted that it is the *Bacillus coli* which infects the appendix. Now the *B. coli* is normally a beneficent inhabitant of the intestine, but when the lower intestine becomes a sewer, and especially when constipation gives a still longer time for putrefactive changes to take place in its contents; the *B. coli* develops pathogenic characteristics, may become ambulatory, and may set up a focus for disease in any other part of the body.

The actual increase in appendicitis *pari passu* with the increased consumption of flesh food may, I think, be gathered—even though not necessarily proved—by the following statistics:

Appendix Cases in Hospital.

|                                | 1876. | 1886. | 1896. | 1899. |

—I am, etc.,

London, W.2, Oct. 13th.

JOSIAH OLDFIELD.

SIR,—With regard to the alleged greater incidence of appendicitis in meat-eaters, may I suggest that a comparatively innocent individual is put in the dock?

When a student I read in Michael Foster's truly scientific *Physiology* that carbohydrates mixed with proteins in the stomach delayed the digestion and assimilation of the proteins. It seems to me that here we have one of the great rules of successful dietetics.

In my own practice I have found that by persuading people to simplify their meals—to eat mainly proteins at one meal, keeping the carbohydrates for a non-protein meal—their digestion and general health have greatly improved.

We have had two opposite methods of treatment of uric acid diseases—(1) the Salisbury diet (mainly protein feeding), and (2) vegetarianism, each upheld by its professors to be most successful; two apparently opposite dietaries. What is common to these two methods? Simplicity; the avoidance of mixing indiscriminately in one meal proteins and carbohydrates.

In the same way "liquid dieticians," if one may so call them, have concentrated on the evils of alcohol; when the evils, to any truly scientific observer, are so manifestly its misuse and abuse.—I am, etc.,

Flackwell Heath, Bucks, Oct. 17th.

G. D. PARKER.

#### DEFENCE OF MEMBERS FOR THE ACTS OF LOCUMTENENTS.

SIR,—Some misunderstanding appears to exist with regard to the protection which the two English defence societies afford their members when threatened with proceedings owing to the acts of locumtenents. The council of the Medical Defence Union passed the following resolution on January 21st, 1926:

That from and after the date of this resolution the council may in its discretion assume responsibility for any claim made upon a member in respect of the act or omission of any registered medical practitioner, whilst temporarily employed as locumtenens for such member.

The council of the London and Counties Medical Protection Society, Ltd., passed an identical resolution, and the position of the two societies in this respect is precisely the same.—We are, etc.,

HUGH WOODS,  
General Secretary, London and Counties  
Medical Protection Society, Ltd.

JAMES NEAL,  
General Secretary, Medical Defence  
Union, Ltd.

London, W.C., Oct. 13th.

### THE IMPROVEMENT OF HEALTH-WEEK EXHIBITIONS.

SIR,—During the last twelve months I have been at three health exhibitions in London. The three were arranged by the local Public Health Committee in connexion with their health-week programmes, and were opened with the usual éclat.

The health exhibitions (so called) consisted of stalls for patent tooth-paste, soaps, dried milk, carpet cleaners, gas stoves, and other proprietary articles. In one case practically the only connexion with the subject of the exhibition that I could find was a stall of diseased meat standing outside the exhibition hall, but nobody was in charge to demonstrate it.

Cannot some action be taken to prevent medical officers of health being forced into the invidious position of promoting these exhibitions, which can do nothing in their district but lower the dignity of their department, and are, in fact, little better than trade exhibitions of proprietary articles?—I am, etc.,

A. H. G. BURTON,  
Medical Officer of Health.

Ilford, Essex, Oct. 16th.

### BILLS OF MORTALITY.

SIR,—In the article under the heading "Nova et Vetera" in your issue of October 9th (p. 645) a query is put to the term "burst" as a cause of death given in the Bills of Mortality. I think this is the old term for hernia. In this part of Kent a herniated sheep is still spoken of as burst or bursten.—I am, etc.,

F. WILLIAM COCK, M.D., F.S.A.

Appledore, Ashford, Kent, Oct. 12th.

### Obituary.

DR. THOMAS PERRIN, who died at Aylesbury on October 3rd, received his medical education at St. Thomas's and the London Hospitals, where he obtained the diplomas M.R.C.S., L.R.C.P. in 1899, and graduated M.B. in 1900. In 1905 he obtained the B.S. with honours, and the F.R.C.S. diploma; in 1906 he proceeded M.D., and in 1907 became M.S. He had held appointments as assistant medical superintendent to the City of London Union Infirmary, Bow, clinical assistant in the ophthalmic department of the London Hospital, and ophthalmic house-surgeon to St. Thomas's Hospital. During the war he held a commission as captain in the R.A.M.C., and served as surgical specialist to the Curragh Camp, Colchester, and Wimereux. He was surgeon to the Royal Bucks Hospital and was very popular in the Aylesbury district. He took an active interest in the work of the British Medical Association, being a member of the executive committee of the Buckinghamshire Division from 1913 to 1916, and honorary secretary of the Buckinghamshire Division of the South Midland Branch since 1922; he was also a member of the Local Medical and Panel Committee. A colleague writes: The sudden death of Dr. Perrin came as a great shock to a large circle of friends in the Aylesbury district, where he was held in high esteem; his unassuming manner and kindly and courteous behaviour endeared him to all his patients. He was a keen and scientific worker, and his colleagues on the hospital staff were always glad to have his help and co-operation; it is certain he will be sadly missed.

MR. ARTHUR WALTON ROWE, who died at Margate on September 17th, received his medical education at St. Mary's Hospital and the University of Durham. He obtained the diploma M.R.C.S.Eng. in 1883, and graduated M.B.Dunelm with first-class honours, and M.S. in 1884. The appointments he had held included those of assistant chloroformist and resident obstetrical officer, St. Mary's Hospital, surgeon to Margate Cottage Hospital, and consulting surgeon to the Royal Sea-Bathing Hospital. During the war he held a commission in the R.A.M.C., and retired with the rank of major. He was one of the foremost geological authorities in Great Britain, and took an especial interest in chalk formations. He published in the *Proceedings of the Geological Association* articles on the zones of white chalk of the English coast, including Kent, Sussex, Dorset, Devon, Yorkshire, and the Isle of Wight. He was also an accomplished archaeologist, and was responsible for the excavation of some of the oldest Saxon remains in Kent. Of his native town, Margate, he had completed a very comprehensive survey, and his lectures on its history, illustrated by plasticine models and plans, drew crowded and most appreciative audiences. He was a Fellow of the Geological Society, a member of the council of the Palaeontological Society, and a member of the Geological Association.

The death occurred at 84, Philbeach Gardens, on September 29th of Dr. WALTER THOMAS BEEBY in his eighty-fifth year. Dr. Beeby was a student of Guy's Hospital where he was later house-physician. In 1865 he entered into partnership with the late Mr. James William Iltot of Bromley, Kent, and on Mr. Iltot's retirement and after his death was in partnership with his son Dr. Herbert James Iltot. It was largely owing to Dr. Beeby's influence that the Bromley Cottage Hospital was founded in 1869, and he was the first medical officer, being shortly after associated with Dr. Willey of Bromley, and later with Dr. H. J. Iltot. The hospital, at first on a very small scale, has been much enlarged, until now it is a well equipped institution with more than forty beds; it has attached to it a large staff both of local medical men and of London consultants. Dr. Beeby retired from general practice in 1898 and went to live at Rapallo, where he practised for seven years and had much to do with the building of the English Church of St. George. He then gave up medical practice and lived during the winter and spring months at Levanto, further along the coast. Dr. Beeby had a taste for architectural and antiquarian research, and was the author of a paper read before the Kent Archaeological Society on the Church and Manor of Bromley. He wrote also a useful little book on the parish church of Bromley. He married in 1879 and is survived by his widow. The funeral service was held on October 4th at the parish church of Bromley.

Dr. D'ARCY BENSON, whose death is announced, was the eldest son of the late John R. Benson, who practised for many years at Gympie, Queensland, and was at one time member of the Legislative Assembly for the Peak Down district of Queensland. Dr. D'Arcy Benson practised for some years at Grosmont Pontillas, Herefordshire. Later he was for many years in practice at St. Peter's Port, Guernsey. He was a very keen yachtsman and was the owner of the cutter *May*, 20 tons, in which he made many cruises to the English and French coasts and elsewhere. In 1911 he had to retire from active practice owing to a serious breakdown in health due to infection from a patient upon whom he was operating. He retired to Dublin and became resident physician at Farnham House Mental Home, but his health seriously interfered with his activities there. He went abroad for his health, and after a few years of invalidism he died of bronchopneumonia at Kimberley, South Africa. Dr. Benson was for many years a member of the British Medical Association. He served in the great war with the rank of temporary captain R.A.M.C. Dr. Benson married Miss Mary Louisa Gabriel, daughter of the late Samuel Hawkes

Gabriel of Calne, Wilts. He is survived by his widow and four sons, of whom two are members of the medical profession.

The following professors in foreign medical faculties have recently died: Dr. Commandeur, professor of clinical obstetrics at Lyons; Dr. Rudolf Boehm, formerly professor of pharmacology at Leipzig, aged 82; Dr. Adolf Lesser, formerly professor of internal medicine at Breslau, aged 75; Dr. Lorenzo Mannino, professor of dermatology at Palermo.

## Medico-Legal.

### A DANGEROUS DRUGS PROSECUTION.

THE Marlborough Street stipendiary magistrate (Mr. Cancellor), on October 15th, committed for trial at the Old Bailey John Kynaston, retired lieutenant-colonel R.A.M.C., whose address was given as Langham House, Regent Street, W., on a charge of aiding and abetting, counselling and procuring Rowland Pawsey, registrar of marriages, Marylebone, to attempt to obtain possession of a dangerous drug (powdered opium), contrary to a regulation of the Dangerous Drugs Act, 1920. A further summons of falsely using the description of M.R.C.S. and L.R.C.P.Lond., implying that he was a registered medical practitioner on August 25th, contrary to the Medical Act, 1858, was adjourned *sine die*.

Both summonses were first heard on October 8th, and a report of the hearing appeared in our last issue (p. 716).

Mr. Vincent Evans, for the Director of Public Prosecutions, stated that the defendant treated Mr. Pawsey for catarrh, and handed him a prescription at the top of which were the words: "Late R.A.M.C., L.R.C.P., M.R.C.S." The prescription was signed at the bottom: "Lieutenant-Colonel R.A.M.C., retired, M.R.C.S., L.R.C.P.Lond." His name had been removed from the lists of the two medical colleges in question, and also from the Register by the General Medical Council.

Mr. Edmond O'Connor, solicitor, for the defendant, said his client elected to go for trial on the first summons. He was not a quack, impostor, or adventurer, but a fully qualified medical man placed on the Register in 1885, and remaining there for over forty years. In 1886 he entered the army, serving in India, West Africa, and in the South African war, and in 1905 he was placed upon the retired list. On the outbreak of the great war he was again called up and served in the R.A.M.C. In 1922, in consequence of a dispute between the defendant and the General Medical Council for alleged "advertising," the defendant published a paper in which he said diseases of the tonsils and adenoids need no longer be subject to operative treatment. For this he was found guilty of "infamous conduct from a professional point of view," and his name was removed from the Medical Register. Mr. Pawsey had committed no offence in presenting the prescription. He did not want a dangerous drug and did not care whether what he got was opium or powdered rhubarb. If Mr. Pawsey could not be convicted of an unlawful attempt to obtain a drug, the defendant could not be convicted as an aider and abettor.

Mr. O'Connor further submitted, as a matter of law, that the regulation made by the Home Secretary in 1922, pursuant to the Dangerous Drugs Act, was *ultra vires* because the principal Act did not authorize him to make a regulation dealing with an attempt to obtain possession of a dangerous drug. The preamble to the Medical Act, 1858, showed clearly that what was intended was to distinguish qualified from unqualified practitioners. The defendant had been a fully qualified man since 1885, and nothing that the General Medical Council might do could deprive him of the right to say that he was such to-day. There was nothing in any Act to prevent him from acting as a physician or surgeon to a hospital supported by voluntary contributions. All that the erasing of his name from the Register had deprived him of was the right to sue for his fees, to issue certain certificates, such as for death, or to hold certain public appointments.

Mr. Cancellor: Is it your submission that the defendant is entitled to use the letters M.R.C.P.?

Mr. O'Connor: I do not think it is necessary for me to go so far as that. I say he is a fully qualified medical man.

Mr. Cancellor: Do you say, after he has been struck off the Medical Register, he is a duly qualified medical man?

Mr. O'Connor: I say that he is a fully qualified medical man. The magistrate, in committing the defendant for trial, allowing bail in his own recognizance of £100, said he did so "in view of the great importance of the submission made to him."

### FEES FOR REPORTS TO INSURANCE COMPANIES.

IN the Llandudno county court Dr. S. L. B. Wilks of Colwyn Bay was recently successful in recovering from the executors of a deceased patient his fee for two medical reports; the charge of one guinea for each had been disputed. The reports were supplied to two insurance companies, and it was contended by the defendants that, since the information required for them was already in the possession of Dr. Wilks and had been used in the preparation of a report to the coroner, a fee of half a guinea for each was adequate. The judge, in giving judgement for the plaintiff, said that Dr. Wilks was perfectly justified in making the charge.

## Universities and Colleges.

### UNIVERSITY OF CAMBRIDGE.

At a congregation held on October 15th the following medical degrees were conferred:

M.D.—C. B. S. Fuller.  
M.B., B.Ch.—O. K. Colwill, W. H. Gervis, S. Levy-Simpson.  
M.B.—F. B. Parsons.

### UNIVERSITY OF LONDON.

#### KING'S COLLEGE HOSPITAL MEDICAL SCHOOL.

The following awards have been made: Senior Scholarship for General Clinical Studies, Todd Prize for Clinical Medicine, Special Prize for Diseases of Children and for Orthopaedic Surgery: F. Goldby. Jelf Medal, awarded annually on the senior scholarship examination to the candidate who is second in order of merit: A. W. Kendall. Burney Yeo Scholarship: R. G. Macbeth, Burney Yeo Scholarship (honorary): T. K. Lyle. Burney Yeo Exhibitions: F. O. Mayo and C. B. L. Orme. Raymond Gooch Scholarship: S. R. O. Price. Tanner Prize for Obstetric Medicine: A. P. Ross. Special Prize for Diseases of Children: J. L. Newman. Special Prize for Orthopaedic Surgery: H. L. C. Wood.

### VICTORIA UNIVERSITY OF MANCHESTER.

DR. A. D. MACDONALD has been appointed Lecturer in Experimental Physiology.

Dr. J. B. Duguid has resigned the post of Lecturer in Morbid Anatomy and Histology on his appointment as Lecturer in Pathology in the Welsh National School of Medicine, Cardiff.

### UNIVERSITY OF WALES.

DORIS WILLIAMS has satisfied the examiners in Part II of the examination for the Diploma in Public Health.

### UNIVERSITY OF ABERDEEN.

DR. A. LYALL has been appointed Lecturer in Clinical Chemistry and Clinical Chemist at the Aberdeen Royal Infirmary.

### UNIVERSITY OF EDINBURGH.

THE following candidates have been approved at the examination indicated:

FINAL M.B., Ch.B.—A. I. Barron, O. D. Beetham, H. Caplan, C. W. Clayton, B. G. T. Elmes, W. A. Erskine, E. T. Forbes, W. G. Hardie, J. D. Horsburgh, W. D. Jackson, J. M. Johnston, J. J. Mason, D. O. Peters, G. Phillips, E. M. Robertson, P. M. Scott, E. M. Sewell, F. Sizer, H. Somerville.

### UNIVERSITY OF GLASGOW.

THE following degrees were conferred on October 18th:

M.D.—I. Murray, A. Davidson, P. R. McNaught, P. J. O'Hare.  
M.B., Ch.B.—The degree of M.B., Ch.B. was conferred on the eighty-three successful candidates whose names were printed in our issue of October 9th, p. 668.

\* With high commendation.

The Brunton Memorial Prize, awarded to the most distinguished graduate in medicine of the year 1926, has been gained by Herbert H. Pinkerton.

The West of Scotland R.A.M.C. Memorial Prize, awarded to the candidate with the highest aggregate marks in medicine, surgery, and midwifery in the Final Examinations for the degrees of M.B. and Ch.B. held during the year 1926, has been won by Stuart I. A. Laidlaw.

### ROYAL COLLEGE OF PHYSICIANS OF IRELAND.

THE annual meeting of the Royal College of Physicians of Ireland was held at the College on St. Luke's Day, October 18th.

Professor T. Henry Wilson was unanimously elected president, Dr. T. Solomon vice-president, and Dr. Kirkpatrick and Sir John Moore were re-elected the registrar and representative of the College on the General Medical Council respectively. Four censors were elected, as well as examiners.

Dr. C. J. Ussher Murphy was unanimously elected a Fellow.

### ROYAL COLLEGE OF SURGEONS OF ENGLAND.

A QUARTERLY Council meeting was held on October 14th, when the President, Sir Berkeley Allyn, was in the chair.

The death on September 9th, at the age of 80, of Mr. Herbert William Page, past member of the Council and of the Court of Examiners, was reported, and a vote of condolence was passed.

Sir Holburt J. Waring was re-elected a member of the Committee of Management.

#### Diplomas.

Diplomas in Tropical Medicine and Hygiene were granted jointly with the Royal College of Physicians to twenty-one candidates.

The diploma of Fellowship was granted to John Lewin, M.B., B.S.Lond. (Guy's), and that of Membership to Winifred M. de Kok, T. C. Hunt, S. M. Maltick, A. W. L. Row, H. Smith, Karin Stephen, H. Syed, J. G. T. Thomas.

*Supplemental Charter.*

It was reported that the Supplemental Charter, as prayed for by the College, was approved by the King in Council on July 26th.

*Awards.*

The Sir Gilbert Blane Gold Medal has been awarded to Surgeon Lieut.-Commander Stewart Russell Johnston, R.N., M.R.C.S. (Promotion Examination, 1926). Mr. Kenneth Swire Southam was nominated as the thirty-fourth Jenk's Scholar.

*Annual Report.*

The draft copy of the annual report of the Council was approved.

*Lectures.*

The Thomas Vicary Lecture, on "The significance of anatomy," will be delivered by Professor G. Elliot Smith on Thursday, November 4th, at 5 p.m., and the Bradshaw Lecture, on "Reconstructive surgery of the hip-joint," by Mr. Ernest W. Hey Groves on Thursday, November 11th, at 5 p.m.

## Medical News.

THE next term at the Royal Institution of Great Britain will begin on November 2nd, when Dr. G. W. C. Kaye, superintendent of the physics department of the National Physical Laboratory, will begin a course of Tyndall lectures on the acoustics of public buildings. On December 9th and 16th Sir Squire Sprigge, M.D., Editor of the *Lancet*, will give two lectures—the first on early medical literature, and the second on medical literature in relation to journalism. Two lectures on atmospheric electricity will be given on November 27th and December 4th by Dr. George C. Simpson, Director of the Meteorological Office. All these lectures will be given at 5.15. The lectures at Christmas for a juvenile auditory were founded by Tyndall, and a hundred such courses have now been given. The one hundredth and first will be given by Professor A. V. Hill on "Nerves and muscles: how we feel and move." There will be six lectures, beginning on Tuesday, December 28th. They will be given at 3 p.m. on each day and will be completed by January 8th.

THE secretary of the Royal Westminster Ophthalmic Hospital writes to explain that, although the site and buildings of the hospital have been purchased by Charing Cross Hospital, there has been no fusion of the two institutions. A new freehold site has been purchased in Broad Street, W.C.2, for the erection of a new building to carry on the work of the Royal Westminster Ophthalmic Hospital. It is hoped that building operations will be begun early next year, and completed in the spring of 1928. In the meantime the ophthalmic work is being carried on as usual, and it is expected that there will be no interruption during the transfer to the new building.

THE Fellowship of Medicine announces that Mr. Herbert J. Paterson will lecture on October 25th on gastric hæmorrhage and perforation of ulcers, and on October 28th Mr. Arthur Cheate will lecture on emergencies in aural disease. The lectures on emergencies in medicine and surgery are delivered in the Lecture Hall of the Medical Society, 11, Chandos Street, W., at 5 p.m. On November 9th, at 5 p.m., Mr. C. L. Gimblett will give a lecture demonstration, on the investigation of visual fields, at the Royal Westminster Ophthalmic Hospital. Both the lectures and demonstration are open to members of the medical profession without fee. During November a comprehensive course in venereal disease will be given at the London Lock Hospital. From November 15th to December 4th a course in gynaecology and diseases of children will be available at the Royal Waterloo Hospital, with special reference to endocrine deficiency, blood diseases, thyroid, breast, stomach, gynaecological diagnosis, and ophthalmia neonatorum. The St. John's Hospital will hold bi-weekly lectures in dermatology from November 15th to December 11th; if desired, a course in pathology can be arranged also. From November 22nd to 27th a week's course at St. Mark's Hospital will include all branches of diseases of the rectum. Two late afternoon courses will include one at 4.30 to 6 o'clock in general medicine, surgery, and the specialties at the Hampstead General Hospital from November 1st to 13th, and another at 5 p.m., on selected cases in neurology, at the West End Hospital, 73, Welbeck Street, W., from November 22nd to December 18th. Copies of all syllabuses, the general course programme, and the *Post-Graduate Medical Journal* may be obtained from the Secretary of the Fellowship of Medicine, at No. 1, Wimpole Street, W.1.

THE discussion arranged by the Post-Graduate Hostel, Imperial Hotel, Russell Square, W.C., on Monday next, at 9 p.m., will be on colour vision and colour blindness, and will be opened by Professor Roaf. On Thursday, October 28th, there will be a symposium on "The filled dead tooth as

a source of streptococcal blood infection." Dentists will be welcomed. Dinner will be served at 8 p.m. (price 5s.), and coffee and biscuits at 10 p.m. (6d.).

THE autumn session of lectures and demonstrations arranged by the South-West London Post-Graduate Association at St. James' Hospital, Ousley Road, Balham, S.W., commenced on Wednesday last, when Mr. Norman C. Lake gave his impressions on American surgery. On Wednesday, October 27th, at 4 p.m., Dr. Ivan W. Magill will deal with recent advances in anaesthetics; on November 3rd Mr. Eric Pearce Gould will speak on fractures of the tibia; and on Friday, November 12th, Mr. Swift Joly will lecture on recent advances of urinary surgery. The lecture demonstrations will be continued on subsequent Wednesdays at 4 o'clock until December 8th.

THE session of the Listerian Society of King's College Hospital was opened on October 20th, when a sort of moot was held before the Lord Chancellor to hear a "special jury action." The Listerian oration is to be given by Sir Watson Cheyne, Bt., on April 4th, and the business of the session is to be brought to an end on April 20th, when Mr. A. H. Cheate, F.R.C.S., is to give an address on the detection of simulated ear disease.

THE opening meeting of the new session of the North-Western Tuberculosis Society will be held at the Tuberculosis Offices, Joddrell Street, Hardman Street, Deansgate, Manchester, on Thursday, October 28th, at 3.15 p.m., when Dr. Adams, medical superintendent, Liverpool Sanatorium, Delamere, will give his presidential address on "Tuberculosis: the prospect."

THE University of Bristol Association of Alumni (London Branch) will hold its annual dinner at the Hotel Cecil, Strand, on Friday, October 29th, at 7.45 p.m. Viscount Haldane will preside, and Dr. Sibley, Principal Officer of the University of London, will be the guest of the evening. The honorary secretary is Dr. Elizabeth Casson, Holloway Sanatorium, Virginia Water.

THE annual dinner of the past and present students of the Manchester Medical School will be held at the Grand Hotel, Manchester, on Thursday, November 4th. Tickets (15s. 6d.) may be obtained from the Secretary, Students' Representative Council, The Medical School, Manchester.

THE PRINCE OF WALES has become patron of the Ross Institute and Hospital for Tropical Diseases, Putney Heath, S.W.

At the annual meeting of the Royal Academy of Medicine in Ireland, held on October 8th, Sir James Craig was elected president and Dr. T. P. C. Kirkpatrick general secretary for the session 1926-27. The following were appointed presidents of the various sections of the Academy: Medical, Dr. G. E. Nesbitt; Surgical, Mr. A. Fullerton; Obstetrical, Dr. D. G. Madill; Pathological, Dr. J. W. Bigger; Anatomical and Physiological, Dr. J. M. O'Connor; State Medicine, Dr. V. M. Syngo.

MR. HERMAN CAMERON NORMAN, C.B., has been appointed a member of the Royal Commission on Local Government, in succession to the Hon. Sir Arthur Myers, who died on October 9th. Mr. Norman was secretary of the International Sleeping Sickness Conference in 1907, and in 1920-21 was British Minister at Teheran.

DR. R. CUNYNGHAM BROWN, C.B.E., has been appointed a commissioner under the Mental Deficiency Act, 1913.

THE White Rock baths at Hastings, recently purchased by the Corporation, are to be remodelled at a cost of £102,000. Medical baths are to be introduced and a pump room for the iron waters.

THE late Dr. J. C. McVail, formerly deputy chairman of the Scottish National Health Insurance Commission, who died in August last, left personal estate in Great Britain valued at £10,022.

MR. JOHN D. ROCKEFELLER, jun., has presented three and a half million francs to the University of Strasbourg for the enlargement of the ear and nose clinic and for the completion of various unfinished researches.

PROFESSOR LEJARS of Paris, member of the Académie de Médecine, has been created a commander, and Professor Leriche of Strasbourg an officer, of the Legion of Honour.

THE late Mr. Samuel Turner of West Kirby, who left estate of the gross value of £45,428, with net personality £44,075, bequeathed the whole of his property to his widow for life. After his widow's decease £750 is to be given to the Hospital and West Kirby Cottage Hospital, and the ultimate residue of his estate to the University of Liverpool to be applied as the authorities in their discretion may think fit for the furtherance and advancement of medical research into phthisis and cancer and any kindred diseases.

AN institute of hydrology has recently been founded at medical school of Clermont-Ferrand.

## Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to **The EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.**

**ORIGINAL ARTICLES** and **LETTERS** forwarded for publication are understood to be offered to the **British Medical Journal** alone unless the contrary is stated. The Editor who wish notice to be taken of their communications should authenticate them with their names not

Authors desiring **REPRINTS** of their articles published in the **British Medical Journal** must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs.

All communications with reference to **ADVERTISEMENTS**, as well as orders for copies of the **JOURNAL**, should be addressed to the Financial Secretary and Business Manager.

The **TELEPHONE NUMBERS** of the British Medical Association and the **British Medical Journal** are **MUSEUM 9861, 9862, 9863, and 9864** (internal exchange, four lines).

The **TELEGRAPHIC ADDRESSES** are:

**EDITOR** of the **British Medical Journal**, **Aitiology Westcent, London.**

**FINANCIAL SECRETARY AND BUSINESS MANAGER** (Advertisements, etc.), **Articulate Westcent, London.**

**MEDICAL SECRETARY**, **Mediscera Westcent, London.**

The address of the Irish Office of the British Medical Association is **16, South Frederick Street, Dublin** (telegrams: **Harillus, Dublin**; telephone: **4737 Dublin**), and of the Scottish Office, **6, Drumshough Gardens, Edinburgh** (telegrams: **Associate, Edinburgh**; telephone: **4551 Central**).

### QUERIES AND ANSWERS.

#### TREATMENT OF INFLAMMATORY RASH.

"F. H." desires information about the treatment of a severe and irritating inflammatory rash on the face and neck, which clears up after an attack of influenza or protein shock therapy, but recurs subsequently. Is there, he asks, any means of obtaining lasting improvement?

#### WARTS AND EGGS.

**DR. LEONARD WILLIAMS** (London) writes: Recently, at a dinner table, a lady announced that, having been advised by a beauty specialist to use raw white of egg to improve her complexion, she had done so with conspicuous benefit, but had discontinued it because an American friend had told her that if she persisted her face would soon be covered with warts. Whereupon another lady at the table declared that it was not the white of the egg which provoked warts, but the shell. She went on to explain that this was well recognized in East Anglia, where poultry farm-hands and cooks were known to suffer from warts from this cause. In the discussion which ensued I was appealed to, but I could only reply that I had never heard of warts being due to either of these alleged causes. I should like to know if there is any basis for this indictment of eggs, their insides or outsides, and whether the belief is prevalent in any district besides East Anglia.

#### NERVOUS VOMITING.

**DR. F. G. GARDNER** (Oxford) writes: I suggest that "H. W. B.'s" patient (**BRITISH MEDICAL JOURNAL**, October 9th, p. 670), who is suffering from nervous vomiting, may have astigmatism or some other error of refraction. At any rate, in a case of this kind the eyes should be examined by a specialist.

#### RECURRENT BOILS.

**DR. H. G. FALKNER** (London) writes, in answer to "W. L. O." (October 16th, p. 717), to say that he has treated many cases successfully by ultra-violet rays. If the boil is caught in the inflammatory stage, before any pus formation, it can, he says, be aborted. Baths and local treatment are necessary as well.

**DR. A. E. R. RUTHERFORD** (Westbury-on-Trym) writes: If "W. L. O." (**BRITISH MEDICAL JOURNAL**, October 16th, p. 717) will impress on his patient the necessity of avoiding infection of the skin by scratching, I think the boils will soon cease recurring. Careful disinfection of the nails and, more important still, the use of cotton gloves, at night especially—because scratching and, therefore, infection is the purpose. For many years I have found this method very efficient in such cases. With recurring boils the skin is probably more septic than usual. The object in view is, therefore, the prevention of minute abrasions.

#### MUCOUS COLITIS.

**DR. J. W. KING** (Derby) writes in reply to "R. F.'s" request for suggestions in the treatment of mucous colitis (October 2nd, p. 619): Presuming the condition is not accompanied by enteritis, which of course should be attended to by using a suitable abdominal support, possibly the following may be helpful: Liquid paraffin night and day, in large doses to cause leakage, and a peristaltic tablets after each meal. Once a week give 1 ounce of castor oil an hour and a half before breakfast.

Relieve pain with full doses of extract of belladonna, or, better, belladoline tablets (Sandoz Chemical Company, Bradford). Cease giving intestinal disinfectants, but give a highly dose of colloidal kaolin. Let the patient eat anything she likes, except food with seeds or skins, and, of course, cut down flesh meat to a minimum, or, at any rate, to a small amount daily. Alcohol in all forms to be debarred and plenty of rest advised in the recumbent posture.

### LETTERS, NOTES, ETC.

#### MEDICAL GOLF.

The Medical Golfing Society held its autumn meeting on the links of the Littlestone Golf Club. Good weather and the fine condition of the links contributed to a most successful meeting of over seventy members. The competitions resulted as follows:

**Singh v. Bogey** (for Mr. Max Page's Prize).—C. V. Mackay and Hordman Porter tied at 1 down; won on replay by C. V. Mackay.  
**Four-man v. Bogey**.—H. W. Carson and A. E. Mortimer won at 1 down and J. D. Chaplin, at 2 down.  
**O'Keefe v. Goss**.—The C. at 1 down and at 74 for 85-15 = second and third places. A. Scott-Giddett was fourth with 85-11 = 75. The best scratch score was 74 by T. P. Kolesar.

#### TREATMENT OF PRURITUS ANI.

"J. S." writes: In the **JOURNAL** for October 9th Dr. Ward writes a note on the treatment of pruritus ani, which may be very useful. But is not cleanliness the real secret of success? After many years in India and the observation of the native method there of cleansing the anus after defaecation, I came to look on the European method as very barbarous. An Indian washes the part after defaecation. It is perhaps forty years since Sir William Broadbent advocated the use of water, instead of rags or paper, for this purpose. His method began with the use of paper. The pan was then washed out in the ordinary way, and the water which accumulated in the pan after the flow had ceased he used for thoroughly washing the anus, which he then dried carefully with a small towel. The result was most comforting. He then dwelt on the omission to wash the hands after defaecation, still so common, I fear, even amongst members of our profession, and so prevalent in the world at large. It used to be said that Indians did not care to shake hands with white men from caste ideas, but there is no caste idea about it at all; it was solely because of the dirty habits of white men in connexion with defaecation. Why are pimples so common on the face, particularly about the chin? People do not wash as they should do, and go on picking their faces with their infected nails! White people have many curious habits which are never touched on in the school lectures on personal hygiene, the school lecturer being probably an habitual offender.

"M.R.C.S." writes: I suffered many years from this complaint and cured myself by washing the parts after each motion with cotton-wool and cold water.

#### COITUS INTERRUPTUS.

**MR. FRANK COOK** (London, W.) writes: In his letter on coitus interruptus (October 2nd, p. 632) Dr. Gubbin invites the experience of other practitioners. With regard to the evils resulting from this particular form of contraception, I can fully endorse his opinion. Anyone who has the doubtful pleasure of a considerable number of gynæcæ that the majority of them have account for their symptoms, however much they themselves may insist on an organic source of trouble in that direction. These unfortunate women are only too eager to find a concrete peg whereon to hang their afflictions. Their anxiety is presumably accentuated by a fear of the unknown, and it is perhaps natural that they should prefer to believe they are suffering from an "ulcerated" or "twisted womb," or "diseased ovary." Not infrequently their friends, and even their medical advisers, have already gained a certain amount of kudos by reassuring them accordingly. Some doctors have the happy knack of finding a tangible pelvic lesion to account for all the ills to which the female flesh is heir; those of us whose tactile sense is not so well developed have to search elsewhere for their source. Roughly speaking, these gynæcæ cases resolve themselves into four groups. First, there is the tired mother, who is suffering from an enfeebled abdominal wall and pelvic floor, too many children, and genuine neurasthenia; secondly, there is the unmarried woman, generally of the middle class, who is suffering from a mode of life; thirdly, there is the young woman, who insists that she is swelling and has something growing and moving inside her; and lastly, there is the outwardly healthy married woman of child-bearing age to whom Dr. Gubbin refers. Almost invariably one finds on questioning patients of this latter category that they are in the habit of performing coitus interruptus, although the practice is by no means confined to the hospital class. One often obtains very little thanks for attempting to unravel their problems. This is really a matter for the psycho-neurologist; possibly gynæcologists have not the necessary delicacy of touch, or possibly they have too little time at their disposal to deal adequately with each individual case. Nevertheless, their clinics will doubtless continue to be patronized. The easiest way is a bottle of medicine or a curette, but these are double-edged weapons; once they are applied the treatment itself is thenceforth held to blame.

It is not that gynaecologists are unsympathetic; we realize only too well how real are the symptoms, whatever their origin, and how powerless we are to deal with them effectively. I am by no means opposed to birth control in general, provided rational methods are employed. Unhappily we have not as yet evolved that ideal technique which would go far to solve many of our present-day problems.

DR. ALFRED A. MASSER (Penistone) writes: A short time ago I had a patient who had suffered from pain in both iliac fossae and some backache for twelve months and insomnia. She was childless and 30 years of age, and was five years married. There was some tenderness over the region of the iliac fossae, and on pelvic examination both ovaries were slightly enlarged and tender. On inquiring into the cause of her sterility I found her husband had been practising "withdrawal" since marriage. After pointing out to both the husband and herself the harmfulness of the method, natural intercourse has since been indulged in. The patient's mentality is now much brighter, the ovaries are normal, and her pains and insomnia have disappeared. I have no doubt that the practice is harmful to both the male and female, in the latter case causing possibly an instability of balance of the endocrine organs.

DR. R. MACDONALD LADELL (Birmingham) writes: I was pleased to see the letter from Dr. Gubbin in your issue of October 2nd, in which he calls attention to the nervous symptoms produced by coitus interruptus. I am certain that his experiences can be paralleled by every practitioner once he has learned to look for the syndrome. It is not only the women who suffer, but their partners, too, are apt to develop a mild anxiety state, accompanied by irritability. It would be interesting to know how many judicial separations owe their origin to quarrelsomeness engendered by lack of sexual harmony. Anxiety states are common, too, in young men and women during the "walking out" or engagement period. Sometimes this anxiety becomes localized around some particular organ, and the patient believes that he is about to fall a victim to phthisis, cancer, or heart disease. Every man in general practice should cultivate a sufficient knowledge of sex psychology to be able to recognize and deal with these cases on common-sense, matter-of-fact lines.

#### POISONING BY TOBACCO APPLIED TO THE SKIN.

DR. D. S. ROBERTSON (Moulken, China) writes: With reference to notes published recently on poisoning by tobacco applied to the skin, it is interesting to know that Chinese practitioners of the old school use tobacco juice as a means of treatment in cases of abdominal swellings, such as the splenic enlargement of kala-azar. The juice is extracted from the stem of a well-used pipe and rubbed into the skin over the swelling. This causes vomiting and, in some cases, purging. The belief is that the swelling may be reduced by such means. Splenic enlargements, by the way, are supposed to be caused by an accumulation of air and blood which has coagulated.

#### TEMPORARY EXTRUSION OF THE EYEBALL.

DR. T. LINDSAY (Tooting Bee Hospital) writes to report a case of temporary extrusion of the eyeball in an epileptic imbecile woman, aged 41, which occurred suddenly one morning. He says: I found an object like a small tomato of the transparent skinned variety protruding from the right socket, with the eyelids tucked in behind it. There was no pain or tenderness, and I was able to compress the tumour slightly, restoring the eyelids to their usual position. The edges of the lids were thickened and oedematous. On the following morning the eye, apart from a slight purple tint of the sclerotic, was quite as usual. The eye is a blind one, with an opaque white lens, but, apart from that, is of the usual shape and appearance. No fit was reported during the night, and the condition was simply discovered in the morning. I cannot say how it was brought about, but it showed many of the features of a strangulated hernia.

#### AN IDEAL HOME.

Mrs. NAYLOR-DAVIDSON and her husband, overwhelmed by the post-war difficulties of running their many-roomed old house in Uxbridge, with its far-o kitchen and old-fashioned range, proceeded to build themselves an ideal home for modern conditions a little way out in the country. Mrs. Naylor-Davidson has published a description of this home, illustrated with plans and photographs, under the title "*Over Frays*": an *Original House for Practical People*.<sup>1</sup> Although there may not be a large amount of originality in the actual labour-saving devices embodied in the house, the structure is a compact collection of many things that can make life easy to the harassed housewife. And there was, perhaps, considerable originality displayed in starting with—and, so to say, hanging the house on to—the garage, which is so arranged that it can be converted into a dining room, a smoking room, or a children's playroom. The garage opens out of the drawing room, but means have been taken appa ently to avoid the leakage of petrol fumes. A lavatory with a red glass window serves an extra purpose as a "dark room" for photography. The kitchen is evidently regarded as the *chef d'œuvre* and we have a photograph

of Mrs. Naylor-Davidson cooking at the stove. The kitchen is the smallest room in the house, and is really an annexe to the dining room, cut off by sliding doors. The tables are attached to the wall, and supported by swinging brackets. There is a gas cooker and a hot water circulator, for the house is within range of such useful adjuncts as gas, water, and electricity supplies. As there are five openings in this small kitchen and a special flue over the stove the odours of cooking can be rapidly removed. Mrs. Naylor-Davidson adds to her book some chapters on making a garden and an orchard, a few hints to housewives, and an account of the setting in which the house is built. A note at the end informs readers that if they wish to study the subject of building similar houses they can be received at "*Over Frays*" by appointment for a period not exceeding a quarter of an hour, on payment of a fee of 1 guinea. The book is most attractively got up.

#### PLUMBO-SOLVENT WATERS.

DR. T. D. HARRIES of Aberystwyth sends notes of a simple method for avoiding the dangers of plumbo-solvent water, while not interfering with its natural properties. The addition of lime, chalk, or silicates to a soft water has the effect of destroying the economic and therapeutic values of the water. Dr. Harries says that the Birmingham Corporation has not had very satisfactory results from the addition of lime or chalk to the Rhayader water; and that the expense of chemical methods would be prohibitive, except for the water supplies of rich corporations. Since lead cisterns and cisterns of slate slabs jointed with white lead have been discarded, the only source of contamination left is the lead service pipes. To avoid the danger from water which has stood in these pipes all night, many housekeepers allow a large quantity of water to run to waste the first thing in the morning. The principle of this procedure is right, in Dr. Harries's opinion, but the method wrong, as the waste is unnecessary, and often amounts to as much as twenty gallons. To clear 240 ft. of service pipe it is only necessary to draw off two gallons of water. Dr. Harries suggests that housekeepers should establish a routine practice of emptying the water-closet flushing cistern the first thing in the morning. In this way two gallons of water are withdrawn from the service pipes. The drinking water tap should then be opened for eight or ten seconds, thus allowing about a quart of water to run to waste, and clearing 30 ft. of branch piping. Thereafter the frequent use of domestic taps during the day prevents the possibility of contamination of the water by long standing in the service pipes. If the routine practice of this method were adopted in a town of 10,000 inhabitants, the total loss of water daily would not be more than 5,000 gallons. In observations made on one of the softest and purest waters in the kingdom, Dr. Harries has found that the lead impregnation varied between 0.045 and 0.02 parts in 100,000, so that it would be necessary to drink from one to three and a half gallons of overnight water in order to absorb one thirty-first part of a grain of lead. Consequently Dr. Harries does not believe that there is much chance of lead poisoning under modern conditions of water supply. With his suggestion for emptying the service pipes in the morning the risk is negligible. If any water were found capable of acting on lead pipes to a dangerous extent in six hours, Dr. Harries thinks that the danger might be removed by running the water through a conduit twelve yards in length, containing limestone or marble fragments, before it enters the reservoir. This would reduce the plumbo-solvent action of the water by at least 50 per cent., and, combined with his flushing cistern method, would do away with all risk. At the same time the limestone filter bed would have the disadvantage of diminishing the economic value of the water and render necessary increased expenditure on soap. The limestone bed would be renewed once a year, the disused stone being used for road mending.

#### LIQUOR OPII SEDATIVUS.

MESSRS. ALLEN AND HANBURY ask us to state that the morphine content of liquor opii sedativus (Battley) has been increased from 1.5 to 1.8 per cent., so that each fluid drachm now contains 1 grain morphine. The dose has been reduced from 5 to 15 minims to 5 to 10 minims.

#### 1927 MOTOR CARS.

LAST week's issue of the *Autocar* contained a buyers' guide to 1927 model motor cars. The guide consists of an alphabetical list of all the cars which will be on the British market for the coming year, and gives for each car the country of origin, the annual tax, a full specification, the principal measurements, the number of seats, the weight, and the prices, both for the chassis and the complete car.

#### ERRATUM.

THE paragraph of news relating to Dr. Hermann Brehmer in the *JOURNAL* of October 9th (p. 669) should have stated that the hundredth anniversary of the birth of Dr. Hermann Brehmer was celebrated on August 14th, the famous specialist in tuberculosis having died in 1889.

#### VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 44, 45, 46, 47, 50 and 51 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 48 and 49.

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 167.

<sup>1</sup> "*Over Frays*": an *Original House for Practical People*. By Clarice H. M. Naylor-Davidson. Uxbridge: Printed privately for the Author; London: J. and E. Bumpus, Ltd. 1926. (9½ x 11½, pp. 67; 32 figures, 7 diagrams, 3 plates. £1 1s.)

## British Medical Association.

## PROCEEDINGS OF SECTIONS AT THE ANNUAL MEETING, NOTTINGHAM, 1926.

## SECTIONS OF NEUROLOGY AND PSYCHOLOGY AND OF OPHTHALMOLOGY.

E. FARQUHAR BUZZARD, M.D., F.R.C.P., in the Chair.

## DISCUSSION ON MIGRAINE.

## OPENING PAPERS.

## I.—EDWIN BRAMWELL, M.D., F.R.C.P.,

Moncrieff-Arnott Professor of Clinical Medicine in the University, and Physician to the Royal Infirmary, Edinburgh.

MIGRAINE has engaged the attention of the physician from very early days. Nor is this surprising when we recall the comparative frequency of the disorder, the temporary disabling effects to which it may give rise, the interesting phenomena which it presents, and the uncertainty which still enshrouds its etiology. The subjective symptoms of the classical migraine attack are well known. They have been portrayed in graphic language by many skilled observers from personal experience. A great variety of causes are recognized which serve to determine the paroxysms in individual cases, and yet we must still admit our ignorance as to the nature of the disorder and the mode of action of these varied exciting factors. A discussion such as this serves a useful purpose, since it enables us to refer to additions to knowledge which may have a bearing upon unsolved problems, to review recent suggestions, and to picture where we stand. Etiological considerations are of special interest, and to these more particularly I shall devote my remarks. It is, however, impossible in the time at my disposal to deal adequately with the many views which have been advanced in this connexion. I consequently propose, after some preliminary references to certain observations of etiological significance, to submit for your consideration and criticism the explanation which appears to me to be in closest accord with the facts, believing that by so doing I shall best serve the interests of this discussion.

## Nomenclature.

The nomenclature of medicine is not always all that is to be desired and is apt at times to be misleading. A designation often comes into general usage because it appears for the time being to be the best available. Thus the term depicts a most symptom of many migraine attacks, I may remind you that the paroxysm is not always accompanied by headache, and that the headache is by no means always unilateral. Exception may also be taken to the synonyms "bilious headache" and "sick headache," for sickness and vomiting are not necessary accompaniments, and these epithets tend to perpetuate erroneous etiological conceptions.

## Idiopathic and Symptomatic Migraine.

The desirability of differentiating between a true or idiopathic and a symptomatic migraine has been repeatedly advocated, and I would commend this distinction to your consideration, for it is of undoubted value in diagnosis. Paroxysmal headaches, you will recall, are sometimes met with in cases of brain tumour, in cirrhosis of the kidney, and exceptionally as a late syphilitic manifestation. These headaches, to which the term "symptomatic migraine" is applicable, may be accompanied by vomiting, and the pain may be unilateral. A diagnosis from true migraine may, indeed, be difficult apart from the detection of the underlying process. Hence, when paroxysmal periodic headaches develop in later life, and particularly when there is no evidence of hereditary transmission, the probability that

the headache is symptomatic, in the sense that it may be secondary to one of the organic conditions above referred to, should always be borne in mind.

## Symptomatology.

The symptoms of the classical migraine attack are so well known, to many from personal experience, that to describe them would serve no useful purpose. Living, in his work upon migraine, which was published fifty years ago and is still the classic upon the subject, recognizes four types: first, simple hemicrania in which unilateral headache is the striking feature; secondly, sick headache characterized by is often accompanied by a nausea thirdly, blind headache, so called from the visual phenomena and remarkable obscuration of vision which accompany it; and, fourthly, cases presenting manifestations which indicate "a wider implication of the sensorium, affecting the general sensibility of the extremities, and especially the sense of touch in finger-tips, lips, and tongue in varying degree; sometimes impairing the faculty of expression, producing a striking form of disordered speech, sometimes a confusion of ideas and temporary impairment of memory." This somewhat arbitrary classification is useful since it emphasizes certain prominent features which may dominate the picture in individual cases.

The classical migraine attack comprises an aura which is characterized by visual and it may be other phenomena indicative both of local and general disturbance of cerebral function, headache which is typically frontal and predominantly unilateral, nausea and vomiting. But while this is so I may remind you that headache often constitutes the only striking symptom of the paroxysm; that exceptionally—and this applies especially to childhood—attacks of vomiting may be the only manifestation; that occasionally visual disturbance, aphasia, or paraesthesia may be unaccompanied by either of these symptoms, and that anomalous attacks are met with, undoubtedly migrainous in nature, which are characterized by a transient hemiplegia, by pain which closely simulates a true neuralgia, or by paroxysms of vertigo resembling Ménière's disease. Cases are reported in which migraine has so closely simulated an abdominal condition that a laparotomy has been carried out. Again, I have met with a case in which the gastric crises of tabes were attributed to migraine, the associated organic disease being unsuspected.

## Epilepsy and Migraine Compared and Contrasted.

A relationship between epilepsy and migraine is repeatedly referred to in the literature. These disorders, which are usually classed with the neuroses, present many points in common. Thus both are characterized by paroxysms which tend to recur with periodicity, in both the condition as a rule first manifests itself in early life, and in both there is often a history of familial neuropathic predisposition or direct transmission. Again, in migraine as in epilepsy the attack is often ushered in by an aura, while the paroxysm of migraine may be accompanied by temporary disturbance of sensation, of movement, and of speech, and by some degree of mental confusion. Further, in migraine as in epilepsy a cumulative effect may be observed—that is to say, that an unduly long period of freedom may be followed by an unusually severe attack. It is also of interest to note that, as is the case with epilepsy, attacks of migraine in women are apt to occur about the time of the monthly period, and that they often, though not invariably, cease during pregnancy when menstruation is in abeyance. Then I may remind you that in some cases migraine appears to be replaced by epilepsy, while in others there is an apparent substitution of migraine for epilepsy. Again, there are cases described—and I have met with more than one instance in point—in which anomalous attacks of migraine and atypical epileptic attacks so closely resembled each other as to be almost, if not quite, indistinguishable.

But while migraine and epilepsy present many points in common, the resemblance is superficial and certainly not such as to warrant the assumption of an intimate relationship. The two disorders are, indeed, rarely met with in combination, and a history of epilepsy in a

migrainous family is most unusual. Again, it is to be borne in mind that the slow spread of the migrainous aura suggests a different mechanism from the aura of epilepsy, that in the former disease mental deterioration is not observed, and that migraine, unlike epilepsy, tends to disappear in later life. Both disorders are, it is to be remembered, comparatively frequent. Consequently when migraine and epilepsy occur in the same patient or in the same family due allowance must be made for the possibility of coincidence.

#### *Incidence in Relation to Age, Sex, and Heredity.*

Migraine is a common condition. Some six weeks ago I addressed a short questionnaire to a class of senior medical students. The replies indicated that 15, or approximately 12 per cent., of those present suffered or had suffered from the disorder.

The approximate age incidence is expressed in the following table, in which I have tabulated the age of onset of 54 personally observed cases of true migraine met with in private consulting practice. A precise history as to the age of onset is often difficult to obtain, and I am unable to differentiate the age of onset sharply in relation to the first two decades. I find, for instance, that many patients used the expressions "in childhood," "in boyhood," "in girlhood," "during my school days," "as long as I can remember," etc. In 7 additional cases I have no definite note, and these are not included in this table. I have tabulated in a parallel column the age of onset in 49 cases reported by Dr. Liveing.

*The Age of Onset of Migraine.*

|                      | The Author's Cases. | Dr. Liveing's Cases. | Total. |
|----------------------|---------------------|----------------------|--------|
| 1 to 10 years ... .. | 43                  | 16                   | 78     |
| 10 to 20 " ... ..    |                     | 19                   |        |
| 20 to 30 " ... ..    |                     | 12                   |        |
| Over 30 " ... ..     | 3                   | 2                    | 5      |
| Totals ... ..        | 54                  | 49                   | 103    |

These figures indicate that in three-quarters of the cases true migraine first manifests itself before the age of 20, and that it is most exceptional for the onset to be delayed beyond the thirtieth year. Liveing, I may remind you, was of opinion that there are three incidents which play a prominent role in determining the onset of migraine—namely, the period of the second dentition, the period of puberty, and "the strain upon the nervous system which is apt to precede and attend the entrance on the more serious business of life."

As regards sex, females suffer more often than males. Thus, among my 61 cases there were 43 women and 18 men—a proportion of approximately 7 to 3. It is of interest to note that the female preponderance in Dr. Liveing's series was not nearly so pronounced, for of his cases 29 were females and 24 males—a proportion of 5 to 4.

*Heredity* undoubtedly plays a very striking role in the etiology of migraine. A neuropathic heredity is observed in the great majority of cases, according to Möbius<sup>2</sup> in 90 per cent. Still more striking is the history of *direct transmission*. Thus, among my 61 cases of true migraine there were 23 in which one or other parent had suffered from periodic headaches, and 7 additional cases in which one or more brother or sister had been subject to migraine although the parents had escaped. Thus in 30 of the 61 cases there was a familial history of migraine. Liveing's figures are almost precisely similar, for, referring to his series, he remarks, "I find 26 out of 53, or just half, where migraine was stated to be a family complaint." Charles K. Mills has reported a family in which migraine could be traced through five generations.

Transmission through the mother is more common than through the father. Thus, among my 61 cases, in 14 the mother and in 9 the father had been subject to migraine. This preponderance is still more in evidence among the 15 medical students above referred to, for of these, in 8 the

mother, in 1 the father, and in 1 both parents, had been subject to periodic headache.

These considerations demonstrate that migraine is a disorder which commences during the period of active physical and mental development, which affects females more often than males, which occurs notably in families with a neuropathic taint, and which is directly transmitted, most often through the mother, in about half the cases. The frequency with which various neuroses are met with in migrainous families would appear to indicate a common predisposition which we are perhaps justified in describing as an inherited instability of the nervous system. But the constancy with which migraine itself is directly transmitted can only be explained on the further assumption that the individual who suffers must be predisposed by some additional factor or factors which render him peculiarly susceptible to this disorder.

#### *The Obvious Exciting Causes of the Migraine Attack.*

An attack of migraine can often be attributed to a definite exciting cause. These causes are numerous and vary in individual cases. Among them may be mentioned intense mental application, mental fatigue, physical exhaustion, the menstrual period, eye-strain, fasting or prolonged abstinence from food, the excessive consumption of various articles of diet, alcohol, tobacco, a stuffy room, thunder in the air, exposure to intense cold, etc. Prolonged anxiety and worry are potent causes in producing migraine, and a mental factor without doubt sometimes determines an attack. Among these various exciting causes there are two, I think, which call for special mention at the present time. I refer to eye-strain, the importance of which has recently been insisted on by Hurst, and the psychological factor, which has not perhaps received the attention it deserves.

Eye-strain has from time to time been suggested as a potent cause of migraine. According to Hurst,<sup>3</sup> who revived this view in his Savill Lecture two years ago, eye-strain is of "fundamental importance." Hurst states that during the past five years, since all his cases of migraine have been most thoroughly investigated from the ophthalmic standpoint and the smallest error of refraction corrected, his views regarding the prognosis in migraine have entirely altered.

"Personally," he writes, "I have never yet seen a case in which eye-strain was not present, and I have only seen two in which its correction did not either cure the patient or lead to very considerable improvement" . . . "the reason why the importance of the ocular factor is not more widely accepted is that few oculists trouble to give the attention to a patient with migraine that he deserves."

Although I am satisfied that eye-strain is sometimes an important exciting factor, and that the correction of a refractive error occasionally effects a cure, this is, in my experience, quite exceptional. On the other hand, it is to be remembered that in a large proportion of the cases of migraine seen by the physician the patient has already been examined by an ophthalmologist and any refractive error presumably corrected. The onus of proof in this matter consequently rests with the ophthalmologist, and we shall be interested to hear his views.

Mental factors may play an important role in determining migraine in an individual who is predisposed. The following case is a good illustration.

A woman of somewhat nervous temperament, whose father as also a brother and two sisters had suffered from periodic headaches, married a soldier home on leave from France in January, 1916. Some three or four months later—at a time when her mother, with whom she lived, was ill, her husband in the fighting line, and she overworked and obtaining little sleep—the first migraine attack occurred. The paroxysm was characterized by visual phenomena, headache, etc. A second attack occurred a few months later, and gradually the paroxysms became more frequent. Her first child was born in February, 1918. During the whole period of her pregnancy she was free from attacks, but two or three months after the birth of the child the attacks recurred and continued up to February, 1919, when her husband was demobilized. From that time the attacks ceased and there was no recurrence until March, 1922, two months after the birth of her second child, since which time they have been very frequent and distressing.

The facts are striking and their interpretation is interesting, for the patient attributed the recurrence of her attacks—and I think her explanation was almost certainly

correct—to the fact that from the time of the birth of the second child, though not before, she had been in a constant state of anxiety amounting to a dread lest she should again become pregnant.

Dr. F. G. Crookshank,<sup>4</sup> who has recently emphasized the mental factor in the etiology of migraine, believes that a certain "organ inferiority" is generally obvious. "The defect, as in the case of imbalance (eye-strain), may be an actual cause of cerebral exhaustion by reason of the efforts made to overcome the resulting disability"; or "organ defect may become the excuse, seized upon by the psyche for the maintenance of a persistent psychological attitude." Again Crookshank writes:

"If the present psychological state of anyone who seeks relief from migraine be investigated, it will be found that, although the patient himself will at first deny the fact, yet always the mental content in the neighbourhood of the paroxysm, or during their persistence, is one that, in Adler's phrase, is coloured by repressed 'rage and humiliation.' The sufferer will protest that he feels no rage or humiliation, but, if pressed or moved to speak freely, will admit annoying circumstances that would perhaps provoke feelings of 'rage and humiliation' in anyone endowed with less control and of a coarser nature than himself."

I would have you especially note in passing that, whether the "organ inferiority" postulated by Crookshank results in brain exhaustion or emotional disturbance, these effects are no doubt associated with endocrine disturbance, a matter to which I shall presently refer. The following case is of interest in relation to these observations.

The patient, a man past middle age, who came of a migrainous family on the paternal side, had had but one attack of migraine in the course of his life. The paroxysm, which occurred when he was in the early thirties, was characterized by a typical aura and slight unilateral frontal headache. Upon inquiry it transpired that on the previous day the patient had been both disappointed and annoyed, since he had been unsuccessful in obtaining an appointment after having been given to understand that his chances amounted to a practical certainty.

But if, in an individual who is predisposed by heredity, so many factors of very different kinds may induce a paroxysm, the question arises, In what way do they act? Since they all produce similar effects, is it not a reasonable assumption that they must act through a common mechanism? Our inquiries must consequently be directed to the mechanism in question, and to the manner in which these numerous factors act upon it.

#### *The Symptoms of the Migraine Attack a Consequence of Vascular Disturbance.*

Let us next consider the manner in which the symptoms of the migraine attack are ultimately determined. Evidence of vascular disturbance is often observed during the paroxysm. Thus in the prodromal stage pallor of the face, which may be unilateral, is sometimes referred to, while later the face may be flushed. Again, the temporal artery is often described as hard and contracted. An alteration in the calibre of the retinal arteries—sometimes engorgement, exceptionally contraction—has been noted in some of those cases which have been examined with the ophthalmoscope during an attack. Further, the headache, which tends to come on insidiously and gradually increases in intensity, is often—I think I may say usually—described as throbbing in character, and may be alleviated by pressure on the common carotid artery. These observations suggest that similar changes may perhaps also occur in the intracranial vessels, and that the paroxysm may be a consequence of arterial spasm or other disturbance in the intracranial circulation. Indeed, the strong probabilities would appear to be that some of the phenomena—the disorders of speech, for example, and the unilateral sensory and motor symptoms, which are exceptionally observed it is true—are directly produced by a localized spasm of the cerebral arteries, and a consequent interference with the blood supply. The vascular view receives some support from the observations that migraine has been met with in Raynaud's disease, that isolated instances are recorded by Thomas<sup>5</sup> and others in which the hemianopic and other cerebral symptoms have eventually become permanent, and that in a case reported by Oppenheim<sup>6</sup> the paralytic symptoms were due to thrombosis of the internal carotid artery. It is of interest, too, in this connexion to recall the recurring transient hemiplegias and aphasias observed in later life in the subjects of arterio-sclerosis, which are,

as a rule, premonitions of a permanent arterial occlusion, and which are commonly attributed to arterial spasm. I may say, too, that I have personally observed cases of migraine in which the attacks have become aggravated with the development of an arterio-sclerosis.

The vascular view also helps to explain the occurrence of symptomatic migraine in interstitial nephritis and as a late syphilitic manifestation, for it may well be that there are here associated changes in the intracranial arteries. J. Herbert Fisher<sup>7</sup> holds that the visual phenomena can only be accounted for by a lesion in the chiasmal region, while others have attributed some of the symptoms to changes in the retina itself. The admission of these possibilities in no way negatives the vascular view. But what of the headache, the origin of which, to quote the words of Hurst, "remains a complete mystery"? May it not also be explained on a vascular basis? The headache, it will be generally admitted, must be referable to the meninges, for the brain substance itself is insensitive. I would suggest that it may be due to the re-establishment of the normal circulation following a spasm, not of the cerebral, but of the meningeal arteries. Some of you have, no doubt, experienced the intense throbbing pain which comes on gradually and may persist for a long time after the gum has been frozen for the removal of a tooth, and you will recall the pain which is experienced if a hand benumbed with cold is plunged into hot water. I submit that the pain of the migraine headache is similar in character and may be analogous as regards the manner in which it is produced; in other words, that it is due either to the gradual re-establishment of the circulation following a spasm of the meningeal arteries or to their subsequent engorgement. This view, I think, receives further support from the fact that a distinct period of time often elapses between the disappearance of the prodromal symptoms and the commencement of the subsequent headache, which develops gradually and is typically throbbing in character.

Objection has been taken to the vascular theory on the ground that it will not explain the cases of so-called ophthalmoplegic migraine. I am inclined, however, to agree with Oppenheim,<sup>7</sup> who, after referring to cases of the kind in which gross changes have been found, remarks:

"The most plausible view seems to me to be the one based on Charcot's opinion, viz., that periodic oculo-motor paralysis is allied to hemiparesis, and like it presumably due to vascular processes. The vascular spasm inhibits the flow of blood to the nerves and thus produces the paralysis."

I would therefore submit for your consideration the suggestion that: The symptoms of the migraine attack are to be accounted for by localized spasm and subsequent relaxation of the meningeal or cerebral arteries, or of both in varying degree, the prodromal symptoms (when these occur) resulting from spasm of the cerebral arteries, while the headache is attributable to re-establishment of the circulation in, and engorgement of, the meningeal arteries.

#### *The Mode of Action of the Obvious Exciting Factors which are Responsible for the Attack.*

Evidence has been submitted which would appear to indicate that the migraine attack may be explained by a spasm of the meningeal and cerebral arteries; a number of factors have been referred to which may excite a paroxysm, and it has been suggested that these must produce their effects by acting upon a common mechanism. The question consequently arises, How are these vascular changes brought about? Although it is true that there is no proof that the cerebral arteries are regulated by a vasomotor mechanism similar to that which regulates the arterial system in other parts of the body, some of the phenomena observed during the migraine attack—the altered colour of the face, the unilateral hyperidrosis, and the contraction of the temporal artery which is often referred to—are clearly due to a disturbance of the sympathetic. Consequently it may be assumed with some degree of probability that changes in the meningeal and cerebral arteries may be brought about in a similar manner. But how are these changes actually initiated?

The suggestion that the migraine attack is directly determined by some toxic influence has long been popular. In the days when the humoral origin of disease was

generally accepted, the paroxysm was attributed to a superfluity of bile, and the vomiting which so often occurs towards the end of the attack was regarded as an attempt to rid the body of this noxious humour. Purging was consequently advised as the appropriate treatment. Of recent years migraine has been attributed to disturbance of the hepatic function and intestinal stasis; but I venture to think that there is no evidence to indicate that these conditions play an important role. There has been of late a growing tendency to attach importance to disorders of metabolism and endocrine disturbance in this connexion. The relation of migraine to the function of menstruation is here suggestive. You will recall that not infrequently migraine first makes its appearance about the time of puberty, that there is a tendency for the attacks in some cases to occur with great regularity at the menstrual periods, that the paroxysms are rarely met with during pregnancy, and that they often disappear in later life, although, in my experience, they are not infrequently aggravated during the active changes which accompany the menopause. Again, when we consider the various factors which in individual cases are obviously responsible for exciting the paroxysm, is it not a fact that some of these—physical exhaustion, mental fatigue, and emotion, for example—undoubtedly influence the endocrine secretions, while in addition some of the phenomena observed during the attack are such as might be determined by endocrine disturbance? Although I have had no personal opportunity of observing cases of migraine in the initial stages of the attack, I may remind you that a slow pulse, a low blood pressure, and yawning are referred to as occurring during the premonitory period, that Timme speaks of a low blood sugar and a lowered alkaline reserve, and that polyuria is not infrequent. Some of these observations are undoubtedly suggestive, although they require corroboration and amplification. At the same time it appears not unreasonable to suppose that the obvious exciting factors, or some of those responsible for the determination of the migraine paroxysm, may achieve this result by acting upon the endocrine glands and sympathetic nervous system.

#### Further Etiological Considerations.

But even if it be admitted that the symptoms of the migraine attack are due to vascular changes, and that these are determined in an individual who is predisposed by a variety of factors which act upon the endocrine glands and sympathetic nervous system, the localization of the process still calls for explanation. Why, for instance, should the headache be so often situated in the fore part of the head, why should it be so often unilateral, and why should it in some cases—a minority it is true—be so consistently referred to the same side of the head? In this connexion I would remind you that when several members of a family suffer from migraine the features of the attack often show a close correspondence. Had time permitted I might have cited several instances in point. These observations suggest, do they not, the presence of some factor which is responsible for the localization of the disturbance? May it be that some transmitted anatomical peculiarity constitutes the hereditary predisposing factor? But have any anatomical changes been observed which can be regarded as of etiological significance? Some twenty-five years ago it was suggested by Spitzer<sup>9</sup> that the migraine attack might be called forth by a temporary closure of the foramen of Monro, and that a relative stenosis of the foramen was the essential predisposing factor in migraine. Again, it has been argued by Auerbach<sup>10</sup> that the predisposition to migraine is to be found in a relative disparity between the size of the brain and the cranial capacity. I know, however, of no convincing anatomical evidence in support of these views. Attention has of late been directed to the pituitary gland in relation to migraine. Timme,<sup>11</sup> who has especially advocated this relationship, refers to quite a number of factors which are admitted to result in pituitary hyperactivity and which he believes produce at the same time temporary enlargement of the gland. According to Timme, an unusually small or enclosed sella is the transmitted hereditary factor. When the sella is too small to accommodate the enlarging gland he believes that the surrounding structures are pressed on

and that erosion of the bony capsule may occur. The cessation of the paroxysms in later life are, according to this view, to be accounted for by the accommodative enlargement of the sella turcica and the diminished activity of the gland. J. Herbert Fisher,<sup>4</sup> who also attributes the migraine attack to temporary enlargement of the pituitary, bases his contention upon his belief that there is only one region, and that the interpeduncular space, where a lesion could produce all the variations of the migraine scotoma. But is there any actual anatomical evidence in support of these views? Timme writes as follows in support of his contention:

"Deyl at a Paris International Congress a few years ago reported several cases of migraine in which the *post mortem* showed a unilateral pressure exerted by the enlarged hypophysis on the cavernous sinus. I myself have among my roentgenograms four that show a very marked unilateral erosion of the clinoids in patients suffering from migraine. About ten years ago Playce confirmed Deyl's findings."

Obviously these observations, if corroborated, are of much importance. Indeed, it would appear to be not improbable that some transmitted anatomical peculiarity may constitute the essential factor which determines migraine in an individual who is predisposed by a general neuropathic heredity.

I may summarize these suggestions in the following words. Migraine is met with in individuals who are almost always predisposed by a neuropathic heredity, but in whom some additional factor or factors must be assumed to account for the frequency of direct transmission and the special features of the disorder. The symptoms of the migraine attack may be explained by assuming that there is a localized spasm of the cerebral arteries (accounting for the prodromal symptoms where these exist) or a spasm of the meningeal arteries, with, it may be, subsequent engorgement (accounting for the headache), or of both in varying degree. A variety of obvious exciting factors, both physical and mental, may bring about an attack. These must presumably act through a common mechanism in order to produce a common effect. Phenomena often observed during the attack indicate a disturbance of the sympathetic system, and although there is no proof of the regulation of the intracranial circulation by a vasomotor system, it would appear not improbable that in migraine there may be accompanying changes in the intracranial circulation, and that they may be produced in a similar manner. There is suggestive evidence which would associate migraine with disordered function of the endocrine glands, while, further, some of the most potent obvious exciting factors of the attack—physical exhaustion, mental fatigue, emotion—admittedly influence the endocrine secretions. There is some reason for believing—although it is true there is no definite proof—that a transmitted structural peculiarity may predispose to migraine and determine the special nature and localization of the symptoms.

#### Therapeutic Considerations.

The treatment of every case of migraine constitutes a distinct problem. Migraine is one of those disorders in which a thorough inquiry into the history is a necessary preliminary if the best therapeutic results are to be obtained. There are, I am satisfied, few cases which so well repay the time devoted to their investigation from the therapeutic standpoint. The first essential in treatment consists of necessity in a careful review of the patient's daily routine and the correction of any apparent exciting factors. Often the patient will mention incidents which he has found by experience will precipitate an attack, while the physician may detect exciting factors to which the patient has attached little importance or which he has obviously repressed. All such factors, whether physical, mental, or dietetic, must be eliminated so far as circumstances permit. Among general measures to which special importance is to be attached are the avoidance of bodily fatigue and brain fag. The patient of sedentary habits must take more exercise and spend more time out of doors. Again, the advisability of avoiding long intervals between meals is to be remembered, and, needless to say, the refraction should be very carefully examined by an expert in every case, and any error, however slight, corrected. The importance of psychological factors must be kept in mind,

the mental attitude of the patient studied, and anxiety, should this exist, where possible relieved. Of late peptone therapy has been attended with promising temporary results. Luminal, bromides, and the nitrites are often of much value, and I would particularly advocate the value of the first, which I usually prescribe in a dose of 1½ grains at bedtime. But these medicinal agents must be administered systematically over long periods if they are to be of real benefit.

## II.—W. HALLIBURTON McMULLEN, O.B.E., M.B., B.S., F.R.C.S.,

Surgeon, Royal Westminster Ophthalmic Hospital.

### MIGRAINE FROM THE OPHTHALMIC STANDPOINT.

FROM the standpoint of the ophthalmologist the most interesting features of migraine are the visual symptoms so frequently associated with attacks, and its relation to certain ocular defects.

One of the most characteristic features of migraine is the occurrence, generally at the onset of a paroxysm, of some kind of subjective sensory disturbance. Although many people suffer from migrainous headaches without any such prodromal symptoms, it is probable that they occur at some time or other in the majority of cases. Visual disturbances are by far the commonest of these subjective sensory phenomena. Their frequency has been variously estimated by different writers. Thus Liveing<sup>1</sup> found that of 60 cases of migraine 37 had scotomata; Gowers<sup>2</sup> estimated that visual symptoms occurred in 50 per cent. of cases; while Möbius<sup>3</sup> noted the occurrence of visual auræ in only 14 out of 130 cases. Jelfie and White<sup>4</sup> state that close questioning reveals the fact that at some time in the course of the disease the majority of patients have had visual symptoms, and that many people who at first deny having had such symptoms will, when shown Airy's drawings of scintillating scotomata, recollect having seen such appearances. I think those of us who have had personal experience of the visual symptoms of migraine are likely to recognize the imperfect descriptions given by patients more easily than those who have not had this advantage. The symptoms are really not easy to describe, and complaints of "dizziness," "spots before the eyes," "blurring," or "dazzling" often prove on close questioning to refer to typical migrainous phenomena. Another thing that tends to prevent recognition of these symptoms is the widespread popular belief that anything that can be described as "spots before the eyes" means only "liverishness," and is not worth talking about.

A very clear description of the visual aura of migraine, based upon personal experience, was given in 1868 by Dr. Hubert Airy,<sup>5</sup> and illustrated by coloured drawings. In 1895 Gowers<sup>6</sup> devoted the greater part of his Bowman Lecture on subjective visual sensations to discussion of the visual spectra of migraine, using as illustrations the drawings made by Airy and other sufferers. Reproductions of some of these drawings were published in the *Transactions of the Ophthalmological Society*, and I recommend all who have not had personal experience to study these reproductions if they wish to get some idea of what many migrainous patients see. In looking at these pictures one should remember to keep the eyes directed to the point of fixation and to bear in mind that the luminosity of the bright lines should be continually changing, so producing a scintillating effect. The subjective visual sensations are very varied; but one feature is, I believe, always present

—a loss of sight in part of the field of greater or less extent. Very commonly there are also subjective sensations of light (migrainous spectra).

The scotoma may be positive or negative, may develop suddenly in its full extent, or may start at a small spot and gradually spread. The spectra, as Gowers pointed out, present as their most important feature a zigzag or angled character, well known in its common curved form as the fortification spectrum. The angled spectrum is associated with a scotoma, generally bounded by the luminous zigzag or definitely related to it. Thus, in the common form of expanding spectrum the part of the field over which the spectrum has passed remains blind for a short time, so that there is a curved (expanding) scotoma bounded peripherally by the bright zigzag line. This relation of the scotoma to the spectrum is, however, by no means constant. In some cases the scotoma develops before the occurrence of subjective sensations of light. In such cases the spectrum may take the form of a stationary or moving angled sphere appearing in the scotomatous part of the field. In most cases the scotoma is limited to one half-field, left or right, and complete homonymous hemianopia is not rare; but such limitation to the fields on one side of the vertical line is by no means invariable. Sometimes a scotoma, with or without associated spectrum, extends across the middle line of the field. Loss of the upper or lower half of the field in both eyes may occur. Rarely, there is a central scotoma, and cases are recorded of transient total loss of vision; but as a rule the fixation point is not involved. The scotomata are nearly always binocular, homonymous, and identical in extent in the two eyes. In a very few cases the scotoma is monocular. For a long time I was doubtful of the occurrence of monocular scotomata. Patients often say that the defect is in one eye, because a defect in one half of the field of both eyes is thought to be due to a fault in the eye on the side of the defect; but a few reliable observers have stated that one eye only may be affected. A well known neurologist has assured me that he has had a monocular scotoma.

The scotomata of migraine usually last but a short time, seldom more than half an hour, though cases of persistent homonymous hemianopia have been recorded by Thomas,<sup>7</sup> Gowers,<sup>8</sup> Ormond,<sup>9</sup> Gordon Holmes,<sup>10</sup> and others.

Visual disturbances are sometimes accompanied by other prodromal symptoms—for example, paraesthesia and aphasia. Usually the type of prodromal symptom is constant in any one individual, but sometimes different symptoms occur in different attacks, and there may be a tendency in the course of years to a gradual change in the type of aura. I know a member of our profession who has suffered at different periods of his life from an extraordinary variety of symptoms, affecting at one time or another nearly all the special senses. When I last heard him speak of his symptoms he described a highly elaborated visual hallucination, which was then the constant precursor of his attacks. With reference to the association of aphasia with visual disturbances, Gowers<sup>11</sup> and others have noted that when aphasia accompanies scotomata the latter are right-sided. One would expect the reverse to be true in left-handed persons, but I know of no observations to this effect.

A discussion of migraine from the ophthalmic point of view would be incomplete without some reference to ophthalmoplegic migraine. Cases of recurrent ocular palsy following attacks of headache of migrainous character were described by Gübler<sup>12</sup> in 1860 and by Saundby<sup>13</sup> in 1882. The first detailed study of the condition is contained in a paper by Möbius<sup>14</sup> published in 1884. The name "ophthalmoplegic migraine" was first suggested by Charcot.<sup>15</sup> In these cases the headache is usually very severe, and lasts longer than in ordinary migraine, generally for several days. As the headache passes off an ocular palsy develops, becoming complete in a few hours. In the majority of cases the third nerve is affected; in a few cases the fourth or sixth nerve is involved. The paralysis persists for a variable period, from a few days to several months, and passes off gradually. Attacks occur at long intervals. With recurrent attacks there is a tendency for the paresis to pass off more slowly and for recovery to be incomplete. Many patients have suffered from ordinary

migraine for years before the first ophthalmoplegic attack, and many suffer from simple migraine in the intervals between the paralytic attacks. In some cases there is a family history of migraine.

The explanation of the ophthalmic symptoms presents a baffling problem. It seems impossible to avoid the conclusion that different parts of the visual apparatus are affected in different individuals. The homonymous and identical bilateral scotoma, with or without spectrum, indicates, of course, a change occurring above the chiasma in the visual tract or centres of one side. The common form of scotoma, starting as a small defect close to the point of fixation and slowly extending towards the periphery, with its advancing margin marked by a bright zig-zag scintillating line, suggests a change occurring in the visual cortex, starting at a spot and gradually spreading—a change presenting two phases—a nervous discharge giving rise to sensation of light, followed by a temporary paralysis causing the scotoma. But it is important to note that this sequence of positive and negative phases is by no means constant, and probably one must not lay too much stress upon it. It is, of course, conceivable that the changes arise lower in the visual paths. It has been suggested that they originate in the basal ganglia, and recent work showing the representation of the fields of vision in the external geniculate bodies makes such a localization reasonable. The by no means rare extension of a scotoma without a break from one lateral half of the field into the other complicates the problem of localization, but still leaves the visual cortex the most probable site of origin. The association of visual disturbances with aphasia or other symptoms suggests some widespread intracranial disturbance in one hemisphere; but to account for a monocular scotoma one must assume that the disturbance arises in the eye itself or in the optic nerve of the affected side. A remarkable case was described by Khen<sup>16</sup> in 1917. A woman, aged 51, had suffered for many years from ordinary migraine with scintillating scotoma, but in occasional attacks the visual aura took the form of a network with hexagonal meshes appearing before one eye. Khen attributed this symptom to entoptic vision of the hexagonal pigment epithelium of the retina. He suggested that the retina might be stimulated by changes in the epithelial cells brought about by impulses conveyed by the centrifugal fibres, whose presence in the human optic nerve was asserted by von Monakow.

The fundi have been examined in many cases during the time that scotomata were present. Some have noted pallor of the disc, others dilatation and pulsation of the retinal arteries, but it is generally agreed that as a rule no abnormal condition is found. Higgens,<sup>17</sup> however, examined a patient on several occasions during temporary attacks of monocular blindness associated with migraine, and found the retinal arteries reduced to mere threads, whilst the veins were distended. Watching the fundus, he could tell when vision was returning by noticing the enlargement of the arteries.

The character of the ocular palsies occurring in the ophthalmoplegic form of migraine indicates affection either of the oculomotor nuclei or of the nerves themselves. Some writers consider that these cases are not really migraine. It is well known that recurrent ocular palsies associated with headache and vomiting may occur over long periods in some cases of definite organic intracranial disease. *Post-mortem* examinations have been made in a few cases of recurrent ocular palsy with migraine-like headache and no other symptoms of nervous disease. In these cases lesions have been found involving the third nerve: meningitis with plastic exudation about the third nerve<sup>18</sup>; fibro-chondroma of the third nerve<sup>19</sup>; tuberculous enlargement of the third nerve at the point where it issued from the crus<sup>20</sup>; a fibroma the size of a split pea in the course of the third nerve.<sup>21</sup> Knapp<sup>22</sup> concludes that the recurrent palsy is due to some vascular change, inflammatory or oedematous, in a focal lesion involving the root of the third nerve. Although the scanty pathological evidence indicates that organic disease may be present in some cases of so-called ophthalmoplegic migraine, the clinical features and histories of many cases are such that one feels bound to regard them as examples of a specially severe form of migraine.

I do not propose to discuss at length the various theories of migraine, preferring to leave that to our neurological colleagues. My own feeling is that the immediate cause of a paroxysm is most probably a vasomotor change. The question of the relation of migraine to other vasomotor neuroses is one of considerable interest, and one which I hope will be discussed by later speakers. I have myself noted an interesting relation between urticaria and migraine in a patient whom I have had under observation for more than twenty-five years. In early life this patient suffered from severe attacks of migraine, starting with scotomata and aphasia. About the age of 25 the attacks of migraine ceased and she became subject to attacks of severe urticaria. The urticaria continued troublesome for some fifteen years, and during that time she was free, or almost free, from migraine. About the age of 40 the urticaria became less troublesome, and finally ceased, but with the cessation of the urticaria she again became subject to attacks of migraine, although less severe and much less frequent than in early life.

Whatever may be the essential underlying cause of migraine, there can be no doubt that it is very often inherited. Farquhar Buzzard,<sup>23</sup> in a recent Lettsomian Lecture, speaking of epilepsy, said that he accepted the view that that disease was a manifestation of instability on the part of some important nervous mechanism closely related to, if not identical with, the vasomotor system. Epileptic attacks he regarded as only the outward and visible signs of some permanent underlying nervous state, which was inherent in a certain proportion of the population. It appears to me that a similar hypothesis best explains the problems of migraine; that in the migrainous patient, too, there is an inherent permanent underlying state of instability of some important nervous mechanism closely related to, if not identical with, the vasomotor system. Given the inherent state, the development of the symptoms of migraine may be due to a great variety of accessory causes—for example, toxæmia, eye-strain, protein sensitization, psychological repressions, etc. Many writers seek to establish one of these accessory causes as the essential factor in the etiology of migraine. So one will claim to cure all cases by a system of dieting, another by correcting errors of refraction, another by psychotherapy, and so on. All such claims to universal efficacy of one line of treatment I believe to be mistaken, but possibly all of them may be effective in some cases by removing accessory causes of the disorder. The conception of migraine as due primarily to some innate peculiarity in the constitution of the nervous system, but liable to be excited or aggravated by accessory causes of various kinds, is no new thing. It was supported by Living in his classical work on the subject, and it still seems the most useful theory on which to base our treatment.

As ophthalmic practitioners we are, of course, especially interested in the question of the part played by errors of refraction and heterophoria in causing migraine. Very different views are held on this question. It may be said that ophthalmologists are not in a position to give unbiased opinions thereon; but even among physicians I find that opinions differ considerably. Thus, quite recently, two distinguished physicians have expressed almost diametrically opposite opinions. On the one hand, Dr. James Collier<sup>24</sup> writes that very undue prominence has been given to the importance of errors of refraction, that the majority of the subjects of migraine have no errors of refraction; and that the correction of such errors has never cured migraine. On the other hand, Dr. Hurst<sup>25</sup> states that his experience points to an ocular origin as being of importance in the great majority of cases, if not in all. He considers that few modern writers give the ocular factor the prominence which he is convinced it ought to have. He states, further, that the most important treatment is the correction of the eye-strain, that personally he has never seen a case in which eye-strain was not present, and only two in which its correction did not either cure the patient or lead to considerable improvement. It appears to me that this question requires joint investigation by physicians, ophthalmologists, and statisticians.

It is impossible for an ophthalmic surgeon to be sure that the migraine cases he sees represent a fair sample

of the migrainous population. Ocular defects are, however, so generally recognized as causes of headache that it is probable that the majority of patients suffering from persistent headaches do sooner or later get their eyes examined. I think all my ophthalmic colleagues will agree with me that errors of refraction are found in a large proportion of the sufferers from migraine whom we see. The errors are usually slight, the commonest being low degrees of hypermetropic astigmatism, often with oblique axes, or against the rule. Slight degrees of heterophoria are also common.

It is not easy to ascertain what relief, if any, patients obtain from correction of their errors. Even though we ask them to report, only a very small proportion do so. But we do know that many patients derive much benefit and that some obtain complete relief. If I find a definite error of refraction I feel I can confidently promise that some relief, possibly very great relief, will be obtained by wearing glasses. Very careful estimation of the errors and accurate fitting of glasses are, of course, essential. It is perhaps not altogether unnecessary to stress these points, for patients are apt to object to the cost. But inaccurate and ill fitting glasses are as likely as not to aggravate the disorder and discredit ophthalmic treatment. If glasses are to be given a fair chance they must be worn constantly.

If we accept the view that many factors may play a part in the etiology of migraine, it follows that very exhaustive examination of the patients is advisable. The physician and neurologist should work in close association, not only with the ophthalmic surgeon, but with the rhinologist, dental surgeon, pathologist, biochemist, psychologist, and other specialists. I venture to suggest that only by well organized team work is it possible to discover the many abnormalities of structure or function which may be in some degree responsible for the symptoms of migraine; and further, that such team work is desirable in order to correct any tendency for specialists unduly to stress the importance of defects found in the organs in which they are most interested.

## GENERAL DISCUSSION.

Dr. WALTER TIMME (New York) expressed his thanks and appreciation at being invited to discuss so interesting a subject as migraine. Professor Bramwell's paper seemed to him to be of much interest, and his exposition of the pathogenesis of the type of migraine chosen by him quite new and probably true. The idea of a latent or premonitory period during which the contraction of the arteries took place, followed by their intermittent resumption of function, accompanied by the throbbing pain of the migrainous attack, seemed to be a simple and adequate explanation. Dr. Timme thought that migraine was a name which covered as many conditions possibly as "cough." Personally, he himself was subject to two kinds, distinctive in character—one superinduced by eye-strain, with an occipital throbbing pain, lasting for a few hours;

and the other produced by mental "fatigue" or moderate fasting, with a severe intratemporal pain, either unilateral or bilateral, which lasted for one or several days. He believed that there were quite a few types other than these, and he had seen them in his patients. One of these types, however—the intratemporal, either unilateral or bilateral—was the one of greater interest to him, and that which he would wish to discuss. In this migrainous attack the patient complained of pain radiating from the intratemporal region towards either or both temples, to the vertex, or to the mid-orbital region. The nature of the pain was described by the patient as a "fullness" within the skull, of throbbing or bursting or corkscrew character, as of something trying to get out, quite different from the band-like type of pressure about the head of the neuroathenic. If the patient were examined closely it was found that the veins of the fundus of the affected side—or both if the headache was bilateral—were markedly distended. Frequently vision was disturbed, ptosis might supervene, a bitemporal and occasionally a homonymous hemianopsia occurred, and diplopia and strabismus took place. In certain rare cases a trigeminal neuralgia might arise in addition. Just before such migrainous attacks began the patient might have an inordinate sense of well-being and a lightness of the head which he soon recognized as premonitory. Frequently a craving for sweets was prodromal. The blood sugar at this time was found relatively low for the patient under observation. Soon the headache arose and the attack was on. During the attack, or just before it ended, polyuria was a frequent symptom. Patients with these attacks at very frequent intervals in their youth grow extremely fast in height—one of the speaker's patients increased 8 inches in one year. Later on in life many such attacks were synchronous with the production of a mild acromegaly. The symptom-complex in these migrainous attacks led him to suspect the pituitary body as the seat of the disturbance. Indeed, the close anatomical relations of this gland to the cavernous sinus laterally on either side with its contained cranial nerves—the third, fourth, ophthalmic division of the fifth, and sixth—as well as the superimposition of the optic chiasm and the slightly more lateral situation of the Gasserian ganglion, might well point to enlargement of the pituitary as the causal factor of the headache with its visual and optic disturbances. When they further recognized that the usual causes for these intratemporal headaches were fatigue, both mental and physical, fasting, sexual excesses, intensive carbohydrate feeding, menstruation, and that they began in that period of life when genital development reached its maturity, the implication of the pituitary became even more probable. If they examined with x rays the sella turcica of these sufferers the evidence became quite complete, for invariably the films showed erosion of the cavity, either of the anterior or the posterior clinoids—usually the latter—evidences of enlargement of the cavity itself (facets), and occasionally even a complete break through the cavity walls into the sphenoidal sinus, or into the general cranial cavity itself. Dr. Timme had a number of such examples in his possession. The enlargement of the pituitary gland which produced these erosions and the concomitant symptoms was probably due to a demand upon it for hyperactivity to compensate for various types of fatigue states in which blood sugar was relatively reduced and blood pressure lowered. They knew that the pituitary gland, as well as the thyroid and adrenals, responded by hyperactivity to similar demands. Furthermore, to complete the evidence, Deyl and Plavec, as Professor Bramwell had said, had reported *post-mortem* evidences of enlarged pituitary glands impinging upon the cavernous sinus and oculomotor nerves in two cases of long-standing and intense migraine. He believed that there existed a group or class of sufferers predestined to those headaches—a class determined by a congenitally small and enclosed sella turcica, and not necessarily by a "neurotic" make-up. Such a class might have other stigmata—such as a small cardio-vascular system, small genitals, a small glandular system generally—with exception of the lymphoid group consisting of tonsils, thymus, liver, spleen, and Peyer's patches, all of which were hypertrophied. This was a group of which, in America, they saw many examples—the status hypoplasticus—or, as

originally known, the status thymico-lymphaticus. In these cases, with their inadequacies—lack of resistance, fatigability, low pressure, and low blood sugar—he believed that a gradually increasing activity of the pituitary (also of thyroid and adrenals probably) occurred, with the production of a true hyperplasia. This gradually, through pressure, caused an enlargement of the sella turcica, with erosions and faceting. But this hyperplasia was of the nature of a compensatory process, overcoming in a measure the inadequacies of the individual—that is, the blood sugar increased, the blood pressure improved, and the fatigability vanished. During this process, before the sella was sufficiently enlarged, migrainous attacks were frequent, owing to the many causes enumerated, each of which produced a rapid demand for pituitary activity. In the course of time—decades usually—the sella became sufficiently enlarged to permit of exacerbations of pituitary activity without undue pressure, and hence the spontaneous cure of these migraine attacks.

As regards the relation of pituitary migraine to epilepsy, which had been touched upon by Professor Bramwell, in Dr. Timme's experience there were two types of epilepsy—one due to pituitary inadequacy, accompanying Fröhlich's adiposo-genital dystrophy, in which the infundibulum was subjected to such pressure as to prevent sufficient circulation of the pituitary secretion; and the other, the low blood sugar type, due to moderate fasting. This blood sugar was lowest, as would be expected, after the long interval without food ingestion between the evening meal and breakfast, and hence the epileptic attack came on in the early morning just upon arising. Both these forms of epilepsy were associated with pituitary inadequacy in many patients, who for similar reasons—associated with small sellae turcicae—also had pituitary migraine. The hereditary factor was the small enclosed sella. (A simple anatomical unit-character in hereditary transmission probably.) It was interesting to note in this connexion that if such patients, before arising in the morning, took some easily digested food, carbohydrate preferably, and waited a little before getting up, no attack would occur. The most easily diffusible carbohydrate was probably alcohol, and, paradoxical as it might seem, a small quantity of whisky, perhaps half an ounce, given daily to these patients before arising, was quite effective in preventing the attack. This was just another example of the folly of treating alike all cases called by the same name, for alcohol in other types of "epilepsy" was apparently bad. Dr. Timme hoped that he had conveyed his idea that there was a pituitary type of migraine, that it was not necessarily a disease process, but a compensatory one tending to final cure of the individual in the gradual enlargement of the sella turcica, and that the headache was merely its hall-mark.

Dr. GORDON HOLMES (London) knew of no subject more suitable for discussion by members of all branches of the profession than migraine, for not only was it one of the most common of the minor maladies, but it was, in his experience, frequently not recognized, owing to the fact that the existence of visual phenomena was generally regarded as a necessary and essential feature. As Professor Bramwell had pointed out, this was by no means so—not more than 50 per cent. of cases ever had teichopsia, and among those who had it the symptom did not accompany every attack. It was frequently said that though visual phenomena occurred in the earlier attacks, they ceased in the third or fourth decade of life. Dr. Holmes had no doubt that migraine was a clinical entity—that is, it had a constant and uniform pathological basis. It was true, as Professor Bramwell had said, that they met with symptomatic migraine in renal disease and other conditions, but these attacks must be separated from true migraine. He agreed with Dr. Timme that a swelling of the pituitary might produce headache and some of the other symptoms he had described so vividly, though it was to him unintelligible how a hyperplasia—that is, an increase in the number of the functional elements of the pituitary gland—could cause symptoms which developed so rapidly and usually passed off in the course of four or five hours.

To treat this common malady rationally it was necessary to have some idea of its pathology, but unfortunately, though theories abounded, facts were few. Professor Bramwell had revived the vasomotor theory; to him (Dr. Holmes) there seemed little evidence in favour of it. Vascular spasm might be due to either some substance circulating in the blood, as an endocrine hormone, or a toxin, or to change in the sympathetic innervation of the arteries. In migraine a local change in the brain must be assumed to explain the visual and other symptoms, and this could scarcely be directly due to a substance circulating in the blood. The acceptance of a sympathetic origin was quite as difficult, for not only had an innervation of the cerebral blood vessels never been demonstrated, but Florey's recent investigations by van Krogh's method of direct observation of the cerebral vessels under a microscope had shown that they could not be influenced by stimulation, section, or other effect of the sympathetic, nor by drugs or extracts that act on the sympathetic system. Consequently not only was there no evidence for this theory, but its possibility seemed definitely disproved.

It had seemed to him that the symptoms of migraine could be more easily explained by the assumption of a local swelling of the brain due to a local and temporary alteration in the osmotic relations of its substance with that of the fluid in which it was bathed, resulting in an imbibition of fluid and consequently a local swelling. That such swellings of the brain did occur they knew from the work of Reichert and others. If it affected the occipital lobe they obtained the positive and negative visual symptoms of migraine, the teichopsia and scotomata, and the swollen brain pressing on the membranes would cause the headache, for the pain must be referred to a disturbance of the meningeal nerves. Two arguments favoured this hypothesis: in the first place, Dr. Holmes had seen several persons who had been subject to migraine, which ceased after an operative or traumatic opening of the skull; and in the second, the peptone treatment, to the success of which Professor Bramwell had referred, might act by inducing changes in the reactions of the proteins.

One form of migraine deserved further notice. Professor Bramwell had referred to migraine-like symptoms occurring in renal and other affections; a recurrence of true migraine might be due to the same and other causes. He had seen many patients who had suffered with migraine in youth and, as so often happens, became free from attacks in middle life, who again became subject to more or less typical attacks during the course of chronic nephritis, arterio-sclerosis, or on exposure to certain poisons, especially alcohol. In some of these cases the recurring attacks reproduced those of earlier life; in others there might be headache and vomiting only, or these associated with various symptoms of cerebral origin. The practical importance of this group of cases was that treatment of the intercurrent affection generally relieved the migrainous attacks.

The treatment of migraine must still remain empirical and mainly symptomatic owing to ignorance of its pathology. Luminal, bromides, and nitrites were helpful in many cases, and it was only by experiment that they could determine which suited any individual patient. They must also search for exciting causes and remove them, whether they were eye-strain, articles of diet, drugs, or psychological factors. Some patients undoubtedly obtained some relief from correction of errors of refraction and imbalance, but in the speaker's experience the value of these measures, even when undertaken with the most scrupulous care, had been grossly exaggerated. Change of occupation and environment had rarely any permanent effect.

Dr. R. G. GORDON (Bath) said that it seemed generally agreed that migraine was a complex subject, and no one could suggest that any one cause was responsible, any more than that any one method of treatment was likely to be successful in every case. Quite apart from the immediate precipitating cause of the attack there did seem to be some inherent defect in these patients which rendered them sensitive to these various influences which had been discussed. It frequently happened that children who suffered from cyclic vomiting developed migraine in later life. So

far as the latter condition was concerned, Dr. Gordon suggested that there was a condition which corresponded to that of ordinary epilepsy, but chiefly affected the occipital lobe rather than the motor area. In the first place, it was generally recognized that the mental attitude of so-called idiopathic epileptics was often, if not always, a peculiar one. There was an egocentricity and narrowness of outlook, combined with a certain truculence, which on further investigation proved to be a compensation for a definite feeling of inferiority. Now in many migrainous patients—the speaker's limited experience would not allow him to say more—there was a similar mental attitude towards life. Further, it was by no means unusual to find symptoms common to both conditions, and Dr. Gordon quoted one case illustrating this contention:

An epileptic gave a history of fits dating from the age of 6, when he was stated to have sustained a severe injury of the right temple. At times the ordinary attacks of grand mal and petit mal were replaced by what were called visual equivalents. In these attacks there appeared before his eyes lights, or sometimes figures which started in the centre of the field of vision and passed over to the right margin of the field. While these were going on he had a right homonymous hemianopsia, which passed off with the end of the attack.

Here apparently there was suppression of the proper highest function of the visual cortex at the left occipital pole with substitution or liberation of lower and less co-ordinated function. This corresponded exactly with what happened in lesions of the motor cortex which caused fits. The explanation of these attacks was, of course, uncertain, but there seemed to be evidence of inherent or acquired injury (by contrecoup) to the superficial cells of the left occipital lobe, so that under certain conditions their function was entirely abrogated, and the activity of deeper and lower grade cells was liberated. In this connexion a result of less severe occipital lesions could not escape notice—that is, the frequency with which typical migrainous attacks were initiated by such an injury. These were characterized by a visual aura followed by headache, and the analogy with the visual epileptic equivalents described above was at least permissible. He would suggest that in these traumatic cases of migraine the condition depended, at least partially, on an interference with the highest grade superficial cells whose function was to control the activity of the lower; further, that a liability to migraine depended on an instability of these highest grade occipital cells, just as an epileptic fit depended on an instability of the highest grade cells of the motor cortex. A further analogy to epilepsy was supplied by the rare occurrence of automatisms following migraine, analogous to the automatisms of epilepsy. A case of typical migraine sometimes showed asocial behaviour with irritability and violence after the attack. This condition passed off and the patient was quite unaware of what he had done. It was not suggested that migraine was epilepsy, but that in certain cases both were manifestations of the same underlying nervous instability which might be due to a variety of causes.

Dr. E. I. Spriggs (Ruthin Castle) said that when he was a student there were many physicians sceptical about the benefits of treatment generally. Although never one of them, he said that there were certain groups of cases whose treatment he undertook formerly without much expectation of benefit, which he now knew could often be relieved. Among these were the sufferers from headache. So many headaches were regarded as chronic, recurrent, familial, or due to the nervous make-up of the subject, that they seemed to be evils to be borne with such alleviation as a few simple medicines could afford, rather than a field for active inquiry and treatment.

To the general physician, as distinguished from the neurologist, there was some danger of headache being an unclassified symptom. Indeed, it was hard to make a classification which was at the same time concise and adequate. Certain clinical types stood out, but many headaches did not conform to a clinical type. This was not the occasion to discuss the classification, but it might be of interest to refer to the proportion of migraine to other headaches in the work of a general physician. Of 1,219 patients at Ruthin Castle in the years 1923 to 1926,

89 (7.3 per cent.) complained of headache as a major symptom on admission. Of these, 4 per cent. (57)—that is about two-thirds—complained of headache as the chief symptom for which relief was sought. Going back a little further than three years Dr. Spriggs had added 11 earlier cases, so as to get 100 consecutive patients complaining of that symptom: 65 were women, of an average age of 44; 35 were men, of an average age of 50. In comparing these with other published cases it should be borne in mind that all were severe. He had compiled a classification, which it would be recognized was founded on the writings of Auerbach, Wilfred Harris, Gordon Holmes, and Pavey-Smith, as a basis on which to found an analysis. Each of the 100 cases was investigated with some care, and after the investigation was made the patients were distributed under the various kinds of headache, as shown in the accompanying table.

It would be seen that 12 cases were classified as migraine—namely, a periodic headache, usually with some kind of aura, going on to vomiting, beginning in childhood or youth, and often hereditary. A difficulty, however, arose. For in this series there were 24 other cases in which the headaches were in all respects typical of migraine, except that they dated back a few years only, were associated with a definite morbid state—gall stones, appendicitis, severe constipation, some definite anxiety or responsibility—and were frequently lessened or abolished on the removal of the associated lesion or strain. There were, therefore, 36 cases out of the 100 in which the headaches were migrainous in type. Were they justified in saying that because in 12 patients the attacks began in childhood, and in some of them were hereditary, these were true cases of migraine, and the others, arising from various causes in later life, were symptomatic migraine? The speaker's experience suggested that the more thoroughly the case was inquired into the less clear this distinction became.

It was admitted that true idiopathic migraine was excited by a variety of adverse influences—strain, overfatigue, want of food, alcohol, bad air, eye-strain, and menstruation. The onset of migraine in adolescence, for example, was ascribed to the strain of entering on the serious business of life. But a greater strain might come later in the conduct of that business, and might give rise to migraine then. He suggested that there was no boundary, from a classification point of view, between the poison or irritation from bad air and eye-strain, and similar effects from constipation or a diseased appendix.

Further, in some of the cases dating back to childhood, a definite physical lesion was present, the treatment of

which relieved or cured the headache. If too much stress was laid upon the distinction between idiopathic and, symptomatic migraine there was a danger lest the idiopathic cases be regarded as definitely diagnosed, and that further steps be not taken. It was a mistake to regard any case as one for prophylaxis and alleviation only until a thorough physical investigation had been made; two cases were described in illustration of this.

Each of these patients gave a typical history of idiopathic migraine. In each a morbid state was present, the relief of which cured the headaches. A number of cases could be quoted in which the systematic treatment of intestinal stasis, leading to regular natural actions, relieved or cured the migraine. The use of irritative aperients was not adequate treatment for constipation. Purgation might relieve a headache, but would do nothing to prevent its recurrence. It might be mentioned here that in two instances a patient had a severe migraine during an x-ray examination with a barium meal, and in each the peristalsis of the stomach was arrested, little or no food passing out. In the last of the above-described cases there was still barium in the stomach twelve hours after the meal. On re-examination the stomach emptied in four hours.

Prophylaxis, by a close review of the daily habits of life and correction of special stresses, was the first line of treatment. Special diets were not of advantage unless directed to a definite morbid state, such as in the alimentary or renal system. In two-thirds of these cases the headaches ceased, and others were greatly benefited. In 4 cases a diagnosis was made but no treatment was given.

The proportion of good results was far higher than Dr. Spriggs would have expected ten years ago, and higher than was expected when the review of the series of cases was entered upon. It was due to (1) the discovery and treatment of a concomitant diseased or disordered state, and (2) the better environment and withdrawal from habitual strains. The factors were environment *plus* morbid state *plus* special strains. The aim was to try to remove both the latter. In many patients freedom was enjoyed if one factor only was removed.

The conclusion Dr. Spriggs drew was that no case of migraine, whether lifelong or arising in adult life, should be accepted as a necessity, to be simply palliated and endured, until after every possible source, not only of mental and psychical, but also of physical disorder, had been excluded so far as possible by a careful investigation and appropriate treatment.

Dr. W. A. Potts (Birmingham) thanked Dr. Timme for his interesting account of the type of migraine associated with functional enlargement of the pituitary gland, which he felt sure was correct. Such cases were like forms of epilepsy due to hypoglycaemia. Although Dr. Potts agreed with Dr. Timme's statement regarding the value of alcohol, he wondered why Dr. Timme had not recommended barley-sugar, which, in the speaker's experience, was the most effective remedy. With reference to Dr. Spriggs's suggestion that fear of life was a marked predisposing cause in adolescents, and later the conduct of life a more potent cause, Dr. Potts asked whether the so-called conduct of life was not, in many cases, still the fear of life. Dr. George Robertson, in his recent interesting Maudsley Lecture, had shown that in middle life the incidence of psychosis was greater in the unmarried, possibly because they were not taking up the full responsibilities of life, and had suggested that responsibility was actually preventive of mental disease. Dr. Potts inquired how many of the cases Dr. Spriggs considered due to the conduct of life were unmarried.

Dr. G. E. NESBITT (Dublin), as a personal sufferer, testified to migraine being a clinical entity. He considered heredity a doubtful etiological factor as he had met with many cases in which no such influence could be traced. Although attacks occurred under all conditions, suggestion might play a part—for example, he had known the elicitation of symptoms from a patient suffering from migraine followed by an attack in the investigator. By a determined effort of concentration it was often possible to maintain central vision during an actual attack in

spite of the absence of peripheral vision. The two theories concerning etiology which most appealed to him were those of (1) vasomotor disturbance, although the cause of such a disturbance had yet to be found, and (2) pituitary enlargement. Why the pituitary alone should swell, however, and not the other endocrine glands, needed explanation.

Mr. E. W. BREWERTON (London) mentioned a case of severe migraine with a visual aura in which great relief had been afforded by complete rest, with the application of heat (an india-rubber hot-water bottle) to the occipital region until normal vision returned; then cold applications until the headache was relieved.

Dr. C. WORSTER-DROUGHT (London) suggested that there was at least one form of migraine or migrainous condition that was very closely allied to epilepsy, if not an actual equivalent of an epileptic attack. Contrary to Professor Bramwell's experience, he had met with several examples of migraine and epilepsy in combination in the same patient; the epileptic attacks were usually of the petit mal type and often occurred early in the morning. Recently he had seen two cases in which petit mal occurring in childhood had been replaced by migraine in adolescence and later life, and he had also seen cases in which the reverse had happened. Concerning etiology, Dr. Worster-Drought could recollect no case of true migraine in which no refractive error was present. Unfortunately, however, correction of such an error was not a certain cure, though many cases were undoubtedly benefited. He recalled a few cases of migraine with severe hemianopia in which unilateral dilatation of the pupil (on the affected side) was present only during the attack. This feature suggested overactivity on the part of sympathetic fibres and lent some support to the vasomotor hypothesis.

As regards medicinal treatment, the most efficient remedy for preventing migraine, or at least diminishing the frequency and intensity of the attacks, was luminal administered in half-grain doses twice or thrice daily over long periods—almost indefinitely. Calcium in large doses was successful in some cases, but many were unrelieved. He had seen several patients benefited considerably, however, by the intravenous injection of a solution of a calcium-urea compound (afonil) in 10 c.cm. doses, carried out twice weekly; as the solution was most irritating to subcutaneous tissues it was necessary to inject it intravenously with the utmost care. In his hands both endocrine and peptone therapy had proved disappointing. He was very interested in Dr. Gordon Holmes's remarks on the possible value of cerebral decompression, as he had met with a case of severe migraine associated with mucous colitis. The patient, a lady now aged 40, developed migraine at the age of 23; the attacks occurred at intervals of about six weeks with prostrating intensity, and all remedial measures proved unavailing. At the age of 33 a subtemporal decompression was performed on the left side, and following this the patient remained completely free from migraine for nearly five years; two years ago, at the age of 38, they had recurred, with an average frequency of one in two months, but with less intensity than formerly.

Professor BRAMWELL, in reply, said that Dr. Timme's observations upon migraine had opened up a broad field. The question whether migraine was to be regarded as a symptom-complex or as a distinct clinical entity was indeed of much interest. As Dr. Gordon Holmes had mentioned, the vascular origin of migraine was first suggested fifty years ago and had had many advocates since that time. Higgens's observations, mentioned by Mr. McMullen, appeared to afford strong corroborative evidence in support of this view, for they indicated that some of the visual phenomena were due to vascular disturbance. The cumulative evidence in favour of the vascular view was indeed, in Professor Bramwell's opinion, very strong despite the experimental results of Florey to which Dr. Holmes had referred. Both Dr. Holmes and Dr. Nesbitt were inclined to discount the tendency to a neurasthenic heredity, but with this opinion he was unable to agree. Mr. McMullen had emphasized the necessity of examining cases of

migraine from every point of view, and Dr. Spriggs had pointed out that a subdivision into true and symptomatic migraine might be dangerous, since the need for an exhaustive examination in the former group might not be realized. With these opinions the speaker was in entire agreement. One of the most important points which had emerged from the discussion was that every case must be considered as a distinct problem from the therapeutic standpoint. Dr. Gordon had emphasized the psychological aspect of the subject, but in the speaker's opinion the relation to epilepsy was not so close as Dr. Gordon would have them believe. Dr. Potts's observations on the effects of the ingestion of sugar were of interest in relation to Dr. Timme's views. In conclusion, Professor Bramwell said that he could lay no claim to originality for the views he had expressed, except perhaps that he had attempted to correlate the etiological data and advance an explanation which he had not heard previously suggested to account for the headache.

## SECTION OF ANAESTHETICS.

SAMUEL JOHNSTON, M.D., President.

### DISCUSSION ON THE FUTURE OF ANAESTHESIA.

#### OPENING PAPERS.

I.—SAMUEL JOHNSTON, M.A., M.D., C.M., F.A.C.P.,  
Lecturer in Anaesthesia, University of Toronto; Chief  
of Anaesthetic Department, Toronto General  
Hospital.

In this workaday world we cannot rest content with the achievements of the past or the progress of the present. Although anaesthesia has passed the venerable age of three-score years and ten I cannot challenge your attention more dramatically to its age-old value than to ask the question, What would happen to-morrow if anaesthesia were blotted from the world to-day? The whole structure of modern surgery, a great part of medical practice, and most laboratory research would go crashing into the abyss of oblivion. Can you conceive of life going on without surcease from pain in face of the fact that, day by day, as many casualties of peace drift into our hospitals as were evacuated from the trenches in the war?

Commonplace as anaesthesia has become to us, it remains so vital a concern to the public that in the United States the only members of the medical and dental professions in the Congressional and New York University Halls of Fame are Crawford W. Long and William T. Morton—those imperishable figures of the first use and public demonstration of etherization for painless surgery. Nor should we forget that had it not been for other immortals of anaesthesia its beneficence might have been lost to us, even after its discovery and demonstration. At a time when the utility of anaesthesia in surgery hung in the balance of space John Snow went into the laboratory and gave the specialty a scientific interpretation and developed satisfactory methods for clinical use. In so doing he became the founder of that illustrious line of research workers and anaesthetists who have graced the specialty since his day.

Had Sir James Young Simpson lacked the courage to defeat the entrenched religionists, or had Her Majesty Queen Victoria failed him in personally approving chloroform *à la reine*, our women of to-day, under the curse of Eve, might still be bringing forth their children in pain and sorrow.

What of dental anaesthesia, had Wells, Morton, Colton, and Evans been timid and unventuring souls instead of the intrepid pioneers they were? We still believe that painless surgery was welcomed with open arms by many, despite the fact that when Hickman memorialized the French Academy, Velpéau and his associates denounced the claims of anaesthesia as a chimera, and only Larrey, of later Napoleonic fame, believed in him. Even in the sixties General Grant had to override the bitterest opposition of his own army medical service in giving Morton a special field ambulance, and permission to anaesthetize the

wounded rebels and Yankees in the later campaigns of the Civil War; thus 10,000 were spared the conscious agony of sitting in at their own operations.

Assembled as we are to-day, we think of anaesthesia as having permeated the known world, and yet among nations of hundreds of millions of souls, painless surgery is as primitive now as it was among the Scythians and Incas and in China in the days of Hoa-tho! When we consider the future of anaesthesia, what of these numberless hordes? In our own midst how many countless things are done in our hospitals, clinics, offices, and the homes of our patients, with never a thought of pain relief? This is one of the remaining cruelties of medical practice, and must pass before we are really entitled to the affection and esteem of the public, who look to us to deliver them from unnecessary suffering.

#### ORGANIZATION.

Organization has been the slogan of progress in all ages, and anaesthesia has had its full quota. The famous old London society, now the Section of Anaesthetics of the Royal Society of Medicine, this Section of Anaesthetics of the British Medical Association, and the Scottish Society of Anaesthetists, all have their counterparts in the Associated Anaesthetists of the United States and Canada and its five regional societies—the Canadian, Eastern, Mid-Western, Southern, and Pacific Coast.

Whether further regional organization would advance the progress of anaesthesia in the British Isles and the status of British anaesthetists is something for your discreet consideration. But this recognition of anaesthesia by the British Medical Association leads us to hope for the development of sections or societies in the colonies, especially Australia, New Zealand, and South Africa, where interest in this connexion is already rife.

In our experience in the United States and Canada regional organization has been found very influential. Our Congresses of Anaesthetists are usually held at the same time and place as the annual meetings of the American Medical Association; the Canadian Anaesthetists meet with the Canadian Medical or some Provincial Association; the Eastern and Mid-Western Anaesthetists usually hold joint sessions during the week of the Clinical Congress of Surgeons; the Southern Anaesthetists meet with the Southern Medical Association, and the California Medical Association usually acts as host to the meetings of the Pacific Coast Anaesthetists. In this way the message of anaesthesia is brought home to members of the most important medical and surgical organizations in at least five metropolitan centres every year. Also the conjunction of such organizations in their meetings provides papers of unusual excellence for the programmes and speakers of very high calibre. In covering so vast a territory, anaesthesia is developed very broadly, and anaesthetists, no matter where located, have every opportunity to attend and profit by the progress that is being reported. In addition, they are given the opportunity to contribute the results of their own work.

The most recent advance in organization is represented by the Anaesthesia Research Society, originally only national, but now international in scope. This society would seem to have an interesting future. So far, during its brief existence, it has organized a Research Committee of the more important scientific and clinical investigators in the specialty; it has established its own journal (*Current Researches in Anaesthesia and Analgesia*); it has issued special monographs, and anticipates reviving an Anaesthetic Year-Book, while at the same time it is finding funds for fostering research. Beginning with 1926, this society is sending its *Journal* to every American and Canadian medical and dental school and society, as well as teaching hospital libraries, with the purpose of making the progress of anaesthesia available in as many places of reference as possible, especially for the generation of anaesthetists which will follow our own. Its Record Committee has developed a uniform anaesthesia chart, and is working on a student's chart for teaching purposes.

The activities of the Research Society have so intrigued pure science that its most noted devotees in the larger universities and laboratories find pleasure in attending the various meetings and presenting their latest investigations

and results. This has enabled the society to provide very remarkable sessions of research papers, and has opened many laboratories for experimental demonstrations. This correlation of interests has brought the achievements of science into the operating room and has sent the clinical problems of anaesthesia back to the laboratory for solution. When time and place have permitted, the programmes of several of the Congresses of Anaesthetists have been equally divided between the usual sessions of papers and lecture demonstrations in laboratories of members of the Research Committee. These latter enable those in attendance to come up to date on the experimental advances in their specialty.

In fostering the fellowship of clinical anaesthesia with pure science, officers of the Associated Anaesthetists and Governors of the Research Society are accustomed to attend the holiday recess meetings of the Federated Societies of Experimental Biology, and it may be said, with pardonable pride, that anaesthesia is often the only specialty participating in these invaluable sessions. As an illustration, following this meeting in Nottingham many of those who are on the Clinic Tour Abroad will go on to Stockholm in pleasurable anticipation of extending co-operative relations with the leaders of the International Congress of Physiologists.

#### TEACHING ANAESTHESIA.

The fact that an older generation of anaesthetists may have lacked something of the laboratory development of present-day medicine does not prevent us from realizing that progress in anaesthesia has always rested on a foundation of clinical practice and experimental science, and in visioning the future we cannot but feel convinced that the coming generation of anaesthetists must have the resources of applied physics, mechanics, chemistry, biochemistry, pharmacology, and pathology as part of the basis of their future careers. Coupled with these, there must also be a well rounded out medical education in the essentials of general practice and of the specialty, and most particularly in the technical and clinical phases of anaesthesia. Such requirements are none too drastic. In fact, a correlation of basic subjects in terms of essential knowledge, in relation to future utility, is merely a common-sense preparation of the medical student for clinical practice. When possible, it is always preferable to develop information and technique on experimental animals than on human beings—always remembering, however, that the practice of medicine is a humane art, and not a cold-blooded laboratory experiment.

For the future it is hoped and expected that all these intimate alliances with the basic and experimental sciences already mentioned will result in the preparation and publication of a loose-leaf textbook on anaesthesia—not for the student, but for the teacher—a textbook that will in résumé exhaust the essential knowledge of the basic and applied sciences in relation to experimental and clinical anaesthesia, and which, from time to time, will be revised to include current and valuable progress. With the consummation of such an arrangement as this anaesthesia could be very readily fitted into the present curriculum, and could be taught intelligently from the viewpoint of applied science in relation to the solution of clinical problems.

#### IDEAL OF SERVICE.

Back of this idea in teaching is an ideal of service. Medical education and organized anaesthesia cannot accomplish their larger purposes merely in securing a steady flow of housemen, proficient enough to satisfy the demands of hospital anaesthesia service and ambitious enough to provide a limited source of recruits for maintaining and extending the ranks of the specialty. If the medical profession is ever to accomplish the broader possibilities of anaesthesia in relation to public service every physician must be qualified to give safely, pleasantly, and efficiently such anaesthesia as may be required in painless childbirth or minor surgery, whether in the home, industrial clinic, or office. Also a certain number of better trained and more competent anaesthetists are required to go into this work in the hospitals of smaller towns, where more and more of the surgery of the future is going to be done. As such anaesthetists develop through years of practice,

they may look forward to staff positions challenging in importance those of the anaesthetists who have elected to stay on in the teaching hospitals in the larger centres and make anaesthesia a metropolitan career. It is understood that, as in the past, teaching hospitals must continue the policy of fostering the development of anaesthetists who vie in calibre with the personnel of any other department.

Details of the plans for securing these three types of anaesthetists would necessarily differ according to local conditions and circumstances. Suffice it to say that they are being secured in certain localities by the co-operation of those interested in accomplishing the ideals of service. The general practitioner anaesthetist is essential to fulfil the obligation of the profession toward the public demand for the universal relief of pain and suffering, whenever and wherever that is possible in medical practice. The clinical anaesthetist must be the internist of the surgical team, and be capable of standing shoulder to shoulder on common ground with his fellows in the College of Physicians. The teaching anaesthetist must be the liaison officer between the research laboratory of the medical school and the surgical department of the hospital. His is the alchemy of transmuting pure science into applied science and practice, for the benefit of all concerned—students, surgeons, patients, hospitals, and his own associates and work in the specialty.

Almost all hospitals of any pretension appreciate the value of expert anaesthesia, and on their staffs have specialists in this work. Opportunities have thus been afforded for the development of the art to a very high degree. The result is that the mortality under anaesthesia has been reduced to a minimum, and patients entering a hospital have for their comfort and safety the services of men of large experience and scientific training in the art of anaesthesia.

In considering the future of the teaching of anaesthesia one naturally takes a survey of its past history and present advancement, and the short period of time that has elapsed since the introduction of this subject in the curriculum of our teaching hospitals is amazing. When it is realized that only within the last twenty-five years have interns in our Canadian hospitals been taught anything of the art of anaesthesia, or that students were given more than one lecture in this subject during their entire medical course, the growth in this specialty, as exemplified in the present system of anaesthesia in the Toronto General Hospital, would appear phenomenal. To-day there exists in this institution, which is affiliated with the University of Toronto, a department in anaesthesia consisting of a chief and eight assistants, all of whom are specialists in the art. This department is as distinct as that of surgery or medicine. The chief is a member of the Medical Advisory Board of the hospital, which is composed of the heads of the various departments. He is also lecturer in anaesthesia in the Faculty of Medicine of the University of Toronto.

As a result of this organization in anaesthesia the student has the advantage of a complete course in every phase of anaesthesia. It is interesting to note here that the department of anaesthesia reaps the benefit of any laboratory experiments in the University of Toronto which may lead to greater safety in the sphere of anaesthesia. During the past year the professor of therapeutics and his assistants have been experimenting with epheдрine, in connexion with blood pressure in anaesthesia, and spinal anaesthesia in particular, and it would appear that this drug has come into a new field of usefulness in raising and sustaining the blood pressure and stimulating the heart action.

But even with such progress we look forward to greater things, and feel that surely it is not too much to hope for the establishment, in the near future, of a Chair of Anaesthesia in every university where medicine is taught.

#### RECORDS AND SAFETY FIRST.

Having for a time exalted perfection of technique above all else, discounted the laboratory, and left the internist outside the hospital portals, surgery, in its fourth and physiological era, has sensed the necessity for essentials other than sublimated dexterity and intuitive infallibility.

Anaesthesia anticipated this change in attitude, and the International Anaesthesia Research Society in developing its uniform Anaesthesia Record—which is really a safety first campaign to prevent needless fatalities—stands ready to co-operate in bringing surgery from under the odium of the time-worn adage, "The operation was a success, but the patient died."

For the future, the patient's fate is not to be left to chance. Hence the Research Society's Record demands the following essentials:

1. Evaluation of surgical and anaesthetic risk before operation, to determine what pre-operative therapy, preparation, and care will add to the prospects for a safer operative ordeal and a more assured recovery.
2. Five-minute-blood pressure guides and safeguards during the entire operative period, to give accurate information to indicate that the patient is still in a zone of safety, or to anticipate the onset of shock and provide remedial measures in time to be effective and life-saving.
3. Evaluation of recovery indices after operation, to determine post-operative therapy and care that will reduce morbidity to a negligible minimum.

Simply as these essentials may be stated, they can be made to include all the resources of experimental and clinical progress in medical practice as adaptable to the preparation, protection, and recovery of operated patients; and the more intensively and routinely anaesthetists and surgical teams extend the use of these safety-first essentials and chart the treacherous course 'twixt life and death, the more gloriously will they serve the interests of safer surgery, and the sooner will they secure the utter and complete confidence of suffering humanity. The "supposedly fit" will cease to pass away unexpectedly and without adequate explanation; the "gravest risks" will no longer be hurried into emergency operations without safeguarding preparation; and there will be no guesswork about what is happening to the patient during the operative period. Finally, the critical seventy-two hours of post-operative anxiety, morbidity, and too frequent mortality, will give way to the blessing of a comfortable and uneventful recovery.

At the present time the Record Committee of the International Anaesthesia Research Society is working on the development of a Teaching Anaesthetic Chart that will enable students and interns to collate in detail the entire fund of their medical knowledge in terms of diagnostic and prognostic aid. This chart will make all pertinent data of the complete history, as well as the results of further indicated examinations and tests, available for exhaustive pre-operative evaluation, operative protection, and post-operative recovery. Time and experience will then show how such charting and evaluation may be simplified and concentrated without sacrificing anything that assures safety-first surgery and anaesthesia.

#### SOURCES OF PROGRESS.

It is readily to be seen, from the records of progress in the past decade, that the specialty of anaesthesia is prepared for future development. Research workers have enthusiastically discovered and perfected newer general and local anaesthetics; manufacturers have made them available in quantity and quality, and with proper equipment for widespread use; and anaesthetists and other specialists have given them rapid and thorough clinical trial. The end is not yet. We seem to stand on the threshold of a new era, in which the very mechanism of anaesthesia itself will be explained, and after that the possibilities of progress would seem to be limitless.

Nothing would seem to be more important to the future of anaesthesia than the co-operation of all concerned in securing supplies of anaesthetics that may be depended on for absolute and undeviating purity and potency. This holds true for the older anaesthetics, such as chloroform, ether, ethyl chloride, and nitrous oxide, as well as for the newer anaesthetics—acetylene, ethylene, and propylene. Strange as it may seem, in spite of all efforts at foolproof production, packing, and storage, anaesthetics still get into the operating room that now and again are open to the suspicion of contamination with impure or deteriorating by-products. It augurs well for the ultimate solution of

this problem that a joint committee to investigate and act in these premises has been established by the British Medical Research Council and the Section of Anaesthetics of the Royal Society of Medicine. No precautions in commercial handling, hospital testing, and operating room use can be too rigid or exhaustive in obviating the occasional disasters, seemingly due to unaccountable and all but inexplicable impurities in anaesthetics.

While connexions that would in any way commercialize the specialty of anaesthesia or the practice of medicine as a whole could not be countenanced, it has remained for the University of Toronto to show the way in which a new clinical remedy (insulin), the product of intensive laboratory research, may be made available through commercial channels without prejudice and to the best interests of everyone. There would seem to be no good reason why newer anaesthetics should not be developed and made available according to the same ethical plan, and the royalties accruing from such used for further research in anaesthesia.

Perhaps without realizing the full significance of what has been done, or its possibilities, anaesthesia has established two central exchanges—one in Manchester and the other in Aron Lake, Ohio. If any of you have had occasion to get in touch with either of these exchanges, to secure information or to be connected with someone who could give it to you, you will readily appreciate my inference that such exchanges and those who man them play an important part in the future of anaesthesia. The specialty is fortunate in having the incumbents of these exchanges peculiarly qualified to carry on the editorial organization and executive duties that are involved.

Regarding the Manchester Exchange, it is splendidly manned by Dr. H. M. Cohen, assisted by Dr. S. R. Wilson, both of whom need no introduction to this Association. They are doing excellent work and receiving loyal support from their fellow anaesthetists.

The "Little Father of Anaesthesia" in the United States and Canada to-day—Dr. Frank H. McMechan, who is the "Aron Lake Exchange"—has the heart-whole affection and devotion of each and all of us who know him. To him belongs the credit of the organization of the existing societies of anaesthetists in these two countries, as well as the founding of the International Anaesthesia Research Society. "The centre of every man's existence is a dream," and anaesthesia and its advancement have been his. His inspiration has come from "a clear vision of the eternal landscape of the past," and to him we owe our meeting here to-day—an achievement truly worthy of a Prometheus!

If other such exchanges can be established to serve as well as the existing two, we should have at least one such exchange in every country in which anaesthesia is recognized and practised as a specialty.

The present Clinic Tour, in which all too few of the leaders of anaesthesia in the United States and Canada have found it possible to participate and meet their fellows in the specialty in Ireland, Scotland, and England, is a sequel to the visits of two of your representatives—Dr. H. E. G. Boyle and Dr. Z. Mennell—to our congresses. In extending and cementing the fellowship of anaesthesia in this personal way, may we not look forward to many joint meetings, as well as to the prospect that out of these associations of the present and past many more may eventuate for the future, and out of them may be developed a College of Anaesthetists, international in scope and purpose? The founding of such a college would go far in raising the specialty of anaesthesia to its proper level, and the qualifications could be made exacting enough for membership to be a challenge of perfection in work and prestige of character.

#### THE PATIENT'S POINT OF VIEW.

In viewing the future of anaesthesia from the annals of the past, one realizes above all else the momentous changes due to scientific progress; but in this vision we must never for one moment forget that in this world of ours from the dawn of history one thing has remained in the very midst of its own wildest vagaries strangely immutable—human nature. For that reason the patient's point of

view remains for the future as it is in the present, and has been in the past, a paramount consideration. Just as the anaesthetists of each generation must be taught their work anew, so, too, the fathers and mothers, sisters and brothers of each generation must be reconvinced of the beneficence of the painless practice of medicine. When all is said and done, a successful profession, like a successful business, is based on the best possible service to the greatest number of people, and anaesthesia will thrive in direct proportion to its satisfied "customers." Physicians themselves are extremely exigent as patients. Bearing this in mind, we can easily fathom the patient's point of view by putting ourselves in his place and doing by him as we would be done by.

In conclusion, it seems to me that, as anaesthetists, our purposes, aspirations, and vision are encompassed in the motto of the Pacific Coast Association, "It is godlike to relieve pain," and that of the Canadian Society, "We safeguard those who sleep."

## II.—WESLEY BOURNE, M.D., Montreal.

### FOSTERING RESEARCH IN ANAESTHESIA.

THE spirit of investigation has always been nearly peculiar to mankind, and therefore research is by no means new, not only with respect to anaesthesia, but also with all other human activities. Research zeal has been particularly keen in recent times, and it is common knowledge that considerable light has been thrown on some of our propositions. As examples I need only make mention of the advances in obstetrical anaesthesia, in insufflation methods, in the many methods of administering anaesthetics generally, the successful employment of the newer gases, our knowledge of the acidosis of anaesthesia, of heat regulation and water exchange, the technicalities of the procedures of regional anaesthesia, the uses of carbon dioxide, of alpha-lobelin, and the borocaines. Just now have come the results of some work done in the Department of Pharmacology of McGill University on the effects of certain compounds on respiration, blood pressure, and recovery when known quantities are added to pure anaesthetic ether.

#### Acetaldehyde.

In the case of acetaldehyde, with concentrations up to 1/2 per cent. respiration was not significantly affected; with 1 per cent. or more the breathing became embarrassed, audibly, visibly, and as shown by tracings. The blood pressure was not affected significantly even though the mixture was administered for as much as three hours. It may therefore be concluded that such percentages of acetaldehyde as may occur in old or improperly prepared ether—that is, less than 1 per cent.—do not affect respiration, blood pressure, and recovery to any appreciable extent even when administered for an unusually long time.

#### Ether Peroxide.

With ether peroxide it was found that with a concentration of 0.5 per cent., or greater, definite effects occurred even after short periods of administration. When the anaesthesia was prolonged these were more marked. Respiratory embarrassment developed, and there was a decided fall in blood pressure. In one instance the heart stopped permanently after one hour of administration. When the percentages were less than 0.5 the effects were negligible. With higher concentrations the depression of blood pressure was extreme. It may be concluded, then, that ether peroxide in ether is only harmful when the concentration approaches 0.5 per cent.

#### Sulphur Compounds.

In the usual method of making ethyl ether side reactions with the production of ethyl sulphide and ethyl mercaptan are conceivable. Both of these substances possess very strong and disagreeable odours, which are detectable when very small amounts are contained in ether. This is particularly the case with the mercaptan, and yet when this impurity is present to the extent of 1 per cent. it does not materially affect the animal after a period of three hours.

With ethyl sulphide the story is different. When 1 per

cent. was employed breathing and blood pressure were both markedly changed. On stopping the anaesthesia there was evidence of good recovery, and yet twelve hours later the dog died after a most severe gastro-enteritis. With smaller concentrations the effects were nugatory even to the extent of three-tenths of 1 per cent. These sulphur compounds, then, do not act alike. Ethyl mercaptan, although a most "Augean" material, does not have much influence when present up to 1 per cent. Ethyl sulphide in 1 per cent. concentration produces an extremely severe gastro-enteritis. With three-tenths of 1 per cent. or less no such effect is caused, and the blood pressure and respiration are not altered.

#### Ketones.

The ketones—acetone, ethyl, methyl, and di-ethyl up to 5 per cent.—did not cause any disturbances worthy of consideration. That these substances are indifferent is clear.

One more instance of the fostering of research comes from the laboratory of pharmacology of McGill University as a corollary of previous works on blood concentration and body temperature in anaesthesia. It may be remembered that an animal under the influence of ether maintains its normal body temperature only when that of the surroundings is very considerably increased (87.8° F.); irrespective of environmental conditions blood concentration occurs. This may be prevented by the use of water or hypotonic solutions, but now, in spite of the previous determined optimum of environmental conditions, the body temperature falls. It was then discovered that with a further elevation of the room temperature (91.4° F.), and with the administration of fluids, there result negligible changes in either body temperature or blood solids.

Morphine, given prior to ether, protects the animal against blood concentration. This fact fits in well with some of the findings in another field of investigation at present being explored by Professor Stehle and myself; in effect, morphine prevents the oliguria or anuria caused by ether.

Now, as it is impracticable for one to work in such temperatures as approach those mentioned, it is quite out of the question for us to have our operating rooms much warmer than they ordinarily are, and as all other methods of maintaining body temperature are rather difficult of control, diathermy was tried. The initial depression of body temperature after ether was followed by a rise to one above the normal after 800 to 1,000 milliamperes. No decided effect on blood concentration was produced by the use of diathermy. When the current was applied before etherization the body temperature was readily increased. Finally, it was found that the ordinary acidosis of anaesthesia was not interfered with by changes in body temperature.

## III.—H. M. COHEN, M.R.C.S., L.R.C.P.LOND., Editor, *British Journal of Anaesthesia*.

### JOURNALS, CURRENT LITERATURE, YEAR BOOK.

WE have our colleagues in the United States and Canada to thank for the establishment of the first regular periodical for anaesthetic literature, which is the now well known *Current Researches in Anesthesia and Analgesia*. However, the genesis may well be placed as far back as Morton's *Circular*, which that unfortunate world benefactor commenced to issue in 1847 and continued at irregular intervals and at his own expense. This *Circular* was the medium in which Dr. Morton published the various experiments of etherization, and it marks the various stages of his fight to establish his claims. At first it appeared almost weekly in the form of a letter of advice, but as its contents increased it was found necessary to enlarge it to four sheets of fine print. Soon the *Circular* grew into a full-sized magazine containing arguments against his opponents, and one issue actually contained nearly one hundred closely printed pages.

The *American Journal of Surgery's Quarterly Supplement of Anesthesia*, now abandoned, which was edited by Dr. F. H. McMechan, for many years held the entire field, with the exception of the *Bulletin* of the National Anaesthesia Research Society.

At the 1922 meeting of the Canadian Society of Anaesthetists Dr. William Webster, in his presidential address, made the suggestion that a committee be formed, with Dr. McMechan as chairman, to go into the question of the establishment of a journal to be devoted entirely to anaesthesia, and very soon *Current Researches* replaced the *Bulletin* as the official publication of the previously mentioned society. In 1923 the *British Journal of Anaesthesia* made its appearance in England.

How far can a science advance without the "printed word"? One thinks that it will be generally accepted as a truism that there can be no progress unless it is simultaneously possible to record that progress. That is especially true where those who are interested in that particular science or art are scattered over great areas, and who, for that reason, are unable by close contact to benefit by the knowledge or efforts of other workers. In anaesthesia this is especially so because of the comparatively few practitioners in any given locality. We are, therefore, dependent on print to convey to us what other men are thinking or doing, and a journal is of the greatest importance to record the progress of our art here, there, and everywhere.

Just as it is a contemporaneous *sine qua non*, much of the development of the future is dependent on its character, for not only do the pages reflect the grade of advance of anaesthesia at a given time, but the type of papers and abstracts published represents its teaching value. What is published to-day may contain a seed which the fertile mind of a reader will cause to blossom forth into something of great value. Or it may whet the appetite of some searcher for truth and spur him on to greater activity. Or it may arouse interest in the laggard and convert him into an enthusiast.

A journal has many advantages over a society. It has no limitations of scope. In its workings it may be likened to the "endless chain," for it not only reaches and influences its immediate subscribers, but through libraries and exchanges it goes out to the farthest ends of the earth, and anything that is of value is transferred to other periodicals throughout the world. Anything worth while is eagerly abstracted, and no language which has its own print will fail to pass the good things along.

A journal's usefulness does not end with its power of dissemination. It brings to its readers the ideas and teachings of others. In its abstracts it serves up in more or less digested form the things that are passing through other minds. Every language makes its contribution, and so the output of the whole world of anaesthesia is recorded number by number for the benefit of all and sundry.

It also has an historical value. One must not forget the men who make up the history of anaesthesia. Our art, though comparatively young in years, is none the less rich in accomplishment. It is a duty, therefore, to bring to public notice the pioneers in anaesthesia—those to whom we owe its inception and development. Although, in a measure, they worked in one limited field of surgery, notwithstanding that the major art owes much of its success to their efforts, it is left to journals of anaesthesia to review their trials and adventures. It is of the greatest importance that the works of such pioneers as John Snow, Clover, Joseph Lister, Paul Bert, and Henry Hill Hickman should be brought to the attention of the medical and anesthetic world; and it is thanks to Dr. Dudley Buxton that the *British Journal of Anaesthesia* has been able to perform this valuable function in England.

While it is deemed to be an essential part of the purpose of a journal of anaesthesia to keep fresh the memory and works of pioneers of the past, we must not overlook those pioneers of modern anaesthesia who are fortunately still with us. We delight to honour them for their labours, and it is felt that we should spread their story broadcast so that it may be possible for active practitioners to profit by their experience as well as to be guided by their example. The anaesthetic world ought to know something of their struggles in working out techniques of practice, in establishing the relative safety of different drugs, as well as something of the story of what must have been a fight to obtain recognition. The pioneers of modern anaesthesia form an important link with the dawn of

anaesthesia, and our journals are needed to record the important stories which they alone can give the world.

Finally, a periodical to serve its true purpose to anaesthesia must bear as its stamp the badge of courage as well as enterprise—courage to light up the thoughts of men, and enterprise to find proper ways and means. There are still great fields for exploration, and this needs constant emphasizing. Who can prophesy what the future holds for the art of painless surgery? There are many Everests in anaesthesia yet to be scaled, and there are many paths still to be explored. Our journalism must breathe and exhale the air of adventure, for the future calls especially for the type of men who will be unafraid to go into the dark places, if need be, to bring about better and safer anaesthesia.

It is therefore clear that the future of our specialty needs a robust journalism. In *Current Researches America* has now an ideal medium, and, taken with the *British Journal of Anaesthesia*, anaesthetists may rest assured that, with their proper support and encouragement, side by side with the advance of anaesthesia will be found their own publications.

IV.—CHARLES W. MOOTS, B.S., M.D., F.A.C.S.,  
Toledo, Ohio, U.S.A.

#### CO-OPERATION WITH THE SURGEONS.

Your description, Mr. President, of the organization of the Department of Anaesthesia in the Toronto General Hospital deserves special mention, apart from the excellent plans you have suggested throughout your discussion on the general topic, "Teaching." A visit to this institution on our way to this meeting easily convinced us of the righteousness of the reputation for leadership which this institution enjoys. It is certainly a far step from conditions existing but a few years since, when it was all too common for the family physician, who probably administered one or two anaesthetics yearly, to accompany the patient to the hospital to make sure that she was safely anaesthetized. It is encouraging to note that a number of hospitals have already fallen in line with the plans of the Toronto General Hospital, and soon there will be a considerably increased number of thoroughly trained medical graduates engaged in the solution of the many intricate problems presenting themselves in the great field of anaesthesia.

As an additional plan for teaching better anaesthesia, may I presume to suggest better organization for opportunities in practical post-graduate work in this field? And as much of our time during the past five years has been given to this endeavour, I will beg your indulgence while offering for your consideration a few of the details.

Being charged with the responsibility of the professional side of the Lucas County Hospital, wherein care is given the indigent cases of both the city and county, as well as the supervision of the surgery in the State Hospital for the Insane, an institution with two thousand beds, it occurred to me that this great wealth of material (2,600 beds) should be placed at the disposal of doctors who might desire advanced work in anaesthesia. As the County Hospital has a well organized staff consisting of thirty-six men of excellent standing in their respective specialties, and well equipped laboratories, an excellent collaboration of data on every case is easily possible. Further, as Dr. McKesson and his associates supervise all anaesthetics in both institutions, we have been able to aid to a considerable extent the many doctors from different lands who show a desire to obtain further experience in the practical administration of the newer gaseous anaesthetics, especially nitrous oxide and ethylene.

A very important part of this plan is to be sure that the entire surgical staff give complete and sympathetic support to the idea of professional anaesthesia. Our surgical staff also understand that it is not necessary to relax the patient to the point of shock in order to accomplish good surgery; that unless they learn to operate under local anaesthesia, as well as under the gaseous general anaesthetic agents, they have not yet acquired the touch of the master surgeon which is so necessary in the protection of the patient.

While the plan thus briefly outlined may not be unusual or final, I believe that if a greater proportion of the leading hospitals will follow some such well defined plan it will give to the profession an impetus that must result in establishing the "future of anaesthesia" in its logical relationship to the other departments of our profession.

#### GENERAL DISCUSSION.

Dr. A. L. FLEMMING (Bristol), who had acted as chairman while Dr. Johnston read the opening paper, said that the President had touched on very vital points. The barriers between the various clinical departments at the hospitals were breaking down, which was a good sign, but in the universities this was not the case yet, a fact which he deplored. A great improvement to be noticed was the closer relation nowadays between anaesthetists, both individual and national. The establishment of the Anaesthetic Exchange in Manchester was a milestone in the history of British anaesthesia. As regards the teaching of anaesthetics, what was necessary was the elimination of chance and art in favour of certainty and science. From the point of view of the public the sooner an art could be turned into a science the better, though the time was not yet when the art could be entirely overlooked. He stressed the necessity of the preliminary teaching of anaesthetic drugs being given by the chemist and not by the anaesthetist. An anaesthetic research committee should be established at every teaching centre and university, and be run by collaboration between the physicist, chemist, biochemist, surgeon, and anaesthetist. The case with which open ether could be administered took away the interest of the student from anaesthetics, which was a pity. He was glad to note that the collaboration between the surgeon and the anaesthetist had increased of recent years.

Dr. R. E. APPERLY (London) queried the effects of aldehyde; the recovery showed irregularity of breathing accompanied by struggling. With minute traces of aldehyde there was sickness and struggling in the case of patients during recovery. Co-operation between the surgeon and the anaesthetist was most necessary in local and regional anaesthesia.

Dr. F. H. McMECHAN (Avon Lake, Ohio) was glad that water-tight compartments had been broken down since anaesthesia had become necessary for research work. Experimenters had thus become converts to association with anaesthetists. The prevention of avoidable deaths on the table must be supplemented by the abolition of unnecessary deaths during the following seventy-two hours. As regards teaching, even the best anaesthetists were limited to certain technical performances. The patient had good surgery and good anaesthesia, but often lacked good doctoring later. The anaesthetist should dominate the preparation of the patient, the patient himself during induction and maintenance of the anaesthetic, and the after-treatment during the post-operative period. The surgeon would thereby be relieved of much work for which he had neither the time nor the training to accomplish with satisfaction.

Dr. S. R. WILSON (Manchester) wished to stress the value of the printed word, as in his opinion the advances made during the last century had been due to this. Meetings also had their value, and he strongly advised anaesthetists to attend and put up with any financial loss incurred. As regards the physician in relation to anaesthesia, any shortcomings in the advice given by the physician must be attributed to the physician and not to the anaesthetist. The physician must take into account not only the systolic pressure but the diastolic, which was the more important. His experience with students and open ether was at variance with Dr. Flemming's. The students were, if anything, too inquisitive.

The PRESIDENT, in reply, said that art could not be taught, for it was inherent in the individual; science wedded to art made the perfect anaesthetist. Pharmacology

and chemistry should be taught in the other departments, and the anaesthetist should confine himself to teaching his students to give anaesthetics safely and comfortably. There was a great difference between a condition of anaesthesia and a condition in which the patient was practically dead to the world. Even under open ether shock and loss of blood might cause death. In collaboration with another worker Dr. Bourne had produced an ether free from impurities, and this could be given to produce an anaesthesia with little or no after-vomiting. The work of Dr. Moots and Dr. McKesson was of the utmost value. Dr. Apperly was right in stressing the value of regional anaesthesia; the trouble was that it had been wrongly applied, as, for instance, in the case of toxic goitres.

#### ACUTE SUFFOCATIVE PULMONARY OEDEMA.

The following three cases may be added to those reported in the JOURNAL during the last few months:

##### CASE I.

Nine weeks ago I was called in the middle of the night to see a patient whom I had been treating on account of double aortic and mitral systolic murmurs. He was sitting up on the side of the bed supported on either side. His face was pallid and grey and a cold perspiration was running down his cheeks and neck. All skin surfaces were cold and clammy. He was breathing in short sharp gasps, using all the muscles of forced respiration. He had a frequent cough and each time brought up pink frothy fluid. His pulse was almost uncountable, feeble but regular. His whole aspect was that of a man about to die—a typical attack of acute suffocative pulmonary oedema. While a hot mustard foot-bath was being prepared he was given a hypodermic injection of morphine gr. 1/3 and atropine gr. 1/120, and a few minutes later one of digitalin, gr. 1/100. In a little more than half an hour he was sitting propped up in bed, breathing easily. His pulse rate had dropped to 80, and his skin was dry and warm. On this occasion some blood was also taken from the median basilic vein. Amyl nitrite inhalation seemed to have no effect.

Within the same week he had three other attacks similar in character and all occurring at night, but on each occasion easily controlled by a hypodermic injection of morphine gr. 1/3, atropine sulphate gr. 1/120. A few days later he had a fifth attack, but this occurred in the daytime. He was then given nightly doses of chloral hydrate gr. 30 and ammon. bromide gr. 30, and leeches were applied to the right costal margin over the liver. He was also given a mixture containing bromide and digitalis as a routine during the day.

For seven weeks he was free from attacks and had been allowed up daily in his room for two hours during the latter part of this time. For a week or ten days his nightly sleeping draught had been at first diminished and then left off without any interference with his sleep.

Suddenly, two nights ago, after he had been some time in bed, an attack started; and, in his own words, he first felt a tightness in his chest, he then came over hot and commenced to cough, and in ten minutes he was in the full blast of an acute suffocative attack. He was given morphine and atropine with digitalin as before, but as half an hour later improvement was only slight atropine alone (gr. 1/100) was repeated, and after another half-hour he was comfortable in bed, with a normal pulse, breathing easily, and able to talk and laugh.

He fell asleep a little later and had a good night and was breathing normally the following morning. This attack—his sixth—was the worst.

He states that in the interval just mentioned he found that the attack seemed to be warded off by inhaling oxygen on the first sensation of any tightness in the chest. Whether an attack would have developed without the oxygen is doubtful. At any rate it inspired him with confidence.

##### CASE II.

Within a week of the first attack in the case just recorded, I was called at 2 a.m. to see a similar case in the same village. This patient, however, had no cardiac murmur, but the auricle was fibrillating. A hypodermic injection of morphine and atropine and one of digitalin very soon cleared up this man's attack, and since then he has not had a recurrence.

##### CASE III.

About eighteen months ago I saw a third case—a severe one—but as this man was known to have albuminuria a hypodermic injection of atropine and digitalin alone was given, without the morphine, and good recovery was also obtained.

It would appear that this condition is not a rare one, but one which a general practitioner is liable to meet at any time. Its onset is exceedingly sudden, and very little warning is given of its advent. Only in my first case did the patient seem to have lost consciousness during the whole attack, and this was only evidenced by the fact that he did not know of the second injection of atropine.

The treatment that seems to have given success in these cases is as follows:

During the attack: Hypodermic injections of morphine and atropine and digitalin; hot mustard foot-bath. A repetition of the atrophine in half an hour if no marked improvement has occurred. Recourse to bleeding in very severe cases in which the above treatment is failing.

Between attacks: Oxygen on the first sign of recurrence; bromide and digitalin in a mixture; chloral and bromide at nights; leeches applied over the liver. General attention to state of bowels and stomach, and removal of septic teeth, etc.

An interesting point is that in none of the three cases was there any general oedema and none of them had rheumatic hearts.

Arlesey, Beds.

W. W. MACNAUGHT, M.B., Ch.B.

The case of acute pulmonary oedema reported by Dr. M. Cohen (BRITISH MEDICAL JOURNAL, March 20th, p. 528) is of especial interest as his patient was a young man. In my experience the usual type of patient is an elderly person with marked arterio-sclerosis and raised blood pressure. The cause of acute pulmonary oedema seems to me an acute failure of the cardiac action or some vasomotor disturbance. The following cases will illustrate this view.

#### CASE I.

A married woman, aged 74, had been under my care for the past five years. She was suffering from valvular disease of the heart with arrhythmia and extra-systoles. She never showed any signs of decompensation, being a very active woman. She had marked arterio-sclerosis, her systolic blood pressure being 180-200 and diastolic 100-110. Her urine contained traces of albumin, the specific gravity being 1012-1016. She was highly myopic, but apart from that the fundus of both eyes was arterio-sclerotic only. So it was a definite case of essential hyperpiesia. Suddenly one night last winter, being in comparatively good health, she developed an attack of acute pulmonary oedema. When I arrived another doctor was already present. The patient was semiconscious, sitting up in bed, pale and cyanotic, with a rapid pulse; systolic blood pressure 120 and diastolic 90. Coarse moist râles were audible all over the chest, and a little froth came from her mouth. After a brief consultation we decided on a liberal venesection from both arms: strophanthin and atropine were injected, followed later by 1/2 c.cm. of pituitrin. The patient still being very distressed a small amount of morphine was injected. Then we left her. Nine hours later we saw her again. She had had a few hours of good sleep, her blood pressure was raised to 140, she was more comfortable and obviously improved. In the urine albumin was present in considerable amount. In five days her blood pressure returned to 180, and she made an uninterrupted recovery. The albumin was gradually reduced to traces only with the rising of the blood pressure. Two months after, again at night, she had another attack with the same symptoms. The same treatment was applied and she was better again in the morning. But her blood pressure rose only to 140, and she complained of severe retrosternal pain, although the heart was not much enlarged by percussion. She was sleepless for three nights. A consultant was called in three days after the night attack, and advised the injection of 1/4 grain of morphine, with strophanthin and atropine. A few hours later she died. It was, in my opinion, a case of acute pulmonary oedema following the hyperpiesial crisis of B. Shaw. Pituitary extract seemed to me the most helpful drug in this case.

#### CASE II.

I was called urgently to see a woman of about 70 whom I had not seen previously. She had marked arterio-sclerosis, systolic blood pressure 220 and diastolic 110. Diagnosis: Acute pulmonary oedema, full consciousness being present. Treatment: Liberal venesection, pituitrin and atropine. Next day the blood pressure had dropped to 180 systolic and 100 diastolic. The pulmonary oedema passed away, but she developed a severe attack of bronchial asthma, which caused anxiety for a few days and subsided in fourteen days. I was under the impression that in this case the pulmonary oedema was caused by a vasomotor disturbance which produced later the attack of bronchial asthma.

London, E.L.

N. PINES.

The following case occurred at Charing Cross Hospital, in August, 1925, when I was house-surgeon to Mr. L. R. Broster.

A woman, aged 42, who had had the right breast removed on the previous day, suddenly developed intense dyspnoea and cyanosis, and frothy blood-stained fluid escaped from the mouth and nostrils. Death occurred within a few minutes, an injection of camphor in oil having no effect.

The post-mortem examination showed that no large blood vessel had been opened at the operation, and apart from the left lung all the organs were healthy. That lung was extremely oedematous, blood-stained fluid pouring off the cut surface; it weighed 18 oz. as against 14 oz. for the right lung. There was no sign of embolism of the pulmonary vessels.

This condition of unilateral pulmonary oedema is sufficiently uncommon to justify a record.

HAROLD AWBROUNX, M.R.C.S., L.R.C.P.

Leyton, Essex.

## Memoranda:

### MEDICAL, SURGICAL, OBSTETRICAL.

#### MENINGITIS AND ENCEPHALITIS DUE TO FOREIGN BODY IN THE CAVERNOUS SINUS.

It would appear that in the following case a piece of wood must have entered the orbit through the upper eyelid when the woman fell. Guided by the bony roof of the orbit the wood must have lodged in the cavernous sinus and broken off, obvious signs of injury disappearing owing to the elasticity of the skin of the eyelid causing it to resume its normal position.

A woman, aged 55, fell and struck her head against some wood outside her cottage door on the evening of July 19th. She was found by her husband a few minutes later and put to bed. Her doctor was called to see her in the morning and said she was suffering from concussion.

On July 23rd she was admitted to the Kent and Canterbury Hospital owing to the condition of the right eye. She had then recovered from the concussion. The right eye was proptosed downwards and forwards. The upper eyelid had a brownish appearance and was slightly oedematous; about its middle was a small graze less than 5 cm. in length which appeared to have involved not more than the superficial layers of the skin. There was no voluntary ocular movement. Examination with the retinoscope showed nothing abnormal within the eye; the temperature was slightly raised.

Two days later the local swelling and oedema, which was never very marked, had disappeared, and the eye could be pushed back into the orbit until it had nearly assumed its normal position. At the same time a curious crepitation could be felt transmitted through the eyeball. X-ray examination of the skull showed no bony lesion.

During the next week the patient became very drowsy and unable to concentrate her attention for any considerable length of time. The temperature chart showed an intermittent fever; the temperature rose to 101° on several occasions. On August 3rd an orbital abscess was diagnosed, and pus was obtained on exploring the orbit above the eyeball. Under a general anaesthetic an abscess the size of a walnut was found, opened, and drained. This, however, produced little effect upon her general condition. On August 6th there was a secondary haemorrhage through the drainage tube saturating the dressings. During the afternoon of August 7th the patient suddenly screamed and jumped out of bed; she died during the evening of the following day (August 8th).

*Post-mortem Examination.*—Acute pyogenic meningitis and encephalitis were found with an acute abscess in the right temporal lobe, communicating with the lateral ventricle, which also contained pus. Most of the substance of the right cerebral hemisphere appeared to be acutely inflamed. On removing the brain six small pieces of wood, the longest being 1.5 by 0.5 by 0.3 cm., were found inside the right cavernous sinus. It could be clearly seen that the infection had entered the cranium through the right orbital fissure. No bony injury was discovered. The eyeball was found intact, while the orbital abscess had been successfully drained.

The small healed wound seen when the patient was admitted to the hospital was the point at which the foreign body had entered. It is probable that the sudden alarm which she experienced the day before she died was due to abscess in the temporal lobe bursting into the lateral ventricle.

I should like to thank Mr. E. D. Whitehead Reid and Dr. J. A. Pringle for permission to publish these notes, and Dr. H. N. Seymour-Isaacs for assisting me at the post-mortem examination.

London, W.

#### PYLOROSPASM DUE TO HELMINTHS.

The following case seems of sufficient interest to be placed on record:

An Indian, aged 43, on December 5th, 1925, at 6 p.m., was seized with acute spasmodic pain in the epigastrium and sensations of dragging from the sides to the centre of the chest. He was intensely nauseated, but did not vomit. The pulse was 96, and the temperature 97.2°. The epigastrium was acutely tender and distended. The stomach resonance was high. The bowels had last been opened by a pill on December 4th.

Terebene (m v) given by the mouth was followed by the passage of flatus. Mindful of a similar case, I injected morphine 1/4 grain. Relief was prompt, and the epigastrium became less tender and presented a tense swelling on the left of the middle line. I gave 1 1/2 oz. of castor oil.

By the next morning he had passed nothing. The pains were returning and the swelling was greater. Castor oil was given again. At noon a motion was passed containing ova of ankylostoma, of *Ascaris lumbricoides*, and of *Trichuris trichiura*. He vomited a quantity of semi-digested rice, castor oil, and mucus. He had not swallowed rice for forty-eight hours. The epigastric swelling vanished and there was no pain. After anthelmintic treatment he passed numerous ankylostomes and six ascariids. He has been under observation ever since and is still well (September 14th).

## HYGIENE AS A WORLD FORCE.

Address at the Opening of the new School of Hygiene  
of the Johns Hopkins University, Baltimore,  
on October 22nd, 1926,

by

ANDREW BALFOUR, C.B., C.M.G., M.D., LL.D.,  
F.R.C.P.Ed.

[Abridged.]

My first duty is to thank most sincerely the authorities of the Johns Hopkins University for the great honour they have done me in asking me to deliver an address upon such an auspicious and important occasion. It would have been very easy for them to find on this side of the Atlantic someone well fitted to perform the task and far more in touch with the great march of public health in the United States; someone also with a more extensive knowledge of hygiene as now practised and developed in countries with temperate climates, for many years of my working life were spent in a land where public health work was in its infancy. It is only since taking up residence in England, and especially since my association with that undertaking which, in large measure, owes its inception and progress to the beneficent generosity of the Rockefeller Foundation, that I have had opportunities of becoming intimately acquainted with those modern movements which have wrought so great a change in the domain of State medicine.

A study of hygiene in England, and particularly of the history of hygiene, has, however, shown me why, in all probability, those responsible desired to have a speaker from that country. England is undoubtedly the cradle of modern hygiene—that is to say, it was in England that the principles and practice of hygiene were first properly developed and placed on a sound administrative basis. Thus other nations have acquired the habit of looking upon England as a leader in the great campaign against disease and death. This habit, flattering to the old country—and the term "old country" includes Scotland, Ireland, and Wales—was undoubtedly justifiable in the early days of public health, and I trust may still be looked upon as wise and salutary, even though the old country has now much to learn from other lands, more especially from this great and wealthy Republic of the West. On the other side of the Atlantic we are perhaps a little apt to forget that America has public health traditions of considerable antiquity, and that, if England is a cradle of hygiene, the United States is indubitably a baby's cot. It could not well be otherwise. Long ago New York was Dutch, and the stout burghers from Holland reached the New World with a great tradition behind them of personal and domestic cleanliness. The Dutch who settled in New York doubtless practised those habits of cleanliness in which they had been reared, and their influence cannot have wholly vanished even when New York, foul, crowded, and unhealthy, had become "The City that Was," so graphically portrayed by Dr. Stephen Smith. Personal cleanliness and cleanliness of the home meant much, but hygiene became a living force only when it extended from the individual to the community, when it became an affair of government, both local and central, and when the aid and majesty of the law were invoked on its behalf. Strange to say, of late years the pendulum has swung back in the old direction, and environment, at one time all-important, is now seen in its proper perspective, while the health of the individual has become a matter of primary importance to the State and to all who have the well-being of mankind at heart.

To-day, in the brief space available, I wish to consider hygiene as a world force, as one of the great factors which have influenced human life and activity, and as possibly the greatest factor which will influence man's progress in the future. To do so, it is necessary to institute a few comparisons.

#### Religion and Hygiene.

While any general comparison of religion in the abstract with hygiene also in the abstract would serve no good purpose, I cannot refrain from contrasting the influence of applied hygiene with that of the application of religious principles in human life and work; in other words, with

organized religion, whether such takes the form of Christianity, Judaism, Mohammedanism, Buddhism, the faith of Confucius, or any of the other creeds which have helped man along the thorny path of existence and guided him, in some measure, through its trials and difficulties. The practice of these beliefs has, of course, had a profound influence upon the world. I think it possible, however, that the hygiene instinct, apparent in some animals be it noted, preceded the religious instinct, and that, even at the present time, the influence of the former is more universal. There are many to whom religion makes no appeal; there are a few races of mankind which appear to be wholly devoid of any religious instinct, but even the most primitive, the most debased, practise certain laws of health. These are essential for life and procreation, and the two ideas which dominate every type of man are those which control the animal world of which he is a part: love of life and the desire for reproduction.

It is instructive to note that some forms of religion had, and still have, a hygienic basis. Rites of purity and certain forms of exercise are, to this day, closely associated with religious observances. Both Moses and Mohammed were hygienists of no mean order. The best features of some faiths are those which relate to the care of the body and the prevention of disease. In India the great system of caste following the institutes of Vishnu and the code of Manu brought the teeming millions of the peninsula some measure of sanitary salvation, while the creeds themselves did little to raise or elevate the masses.

In the hands of man religion playing the part of a world force has unhappily often produced turmoil and bloodshed. On the other hand, hygiene as a world force is a power for peace. Health and its promotion are subjects which sensible men—I say sensible, for we must exclude cranks—can discuss without acerbity and bitterness. I venture to think that the Health Section of the League of Nations is likely to prove the most constructive and most successful part of the great Geneva organization designed to precipitate the millennium. In public health work and propaganda jealousy takes the form of a healthy rivalry. You may envy your neighbour's health record, but there is no sense in being jealous of him because his infantile mortality rate is much lower than yours. The revelation merely stimulates you to further effort, and it is almost inconceivable that nations should go to war in the race to be the fittest, as they do when it is a question of riches or power or *amour propre*, or (in the old days) religion, or self-defence. Yet curiously enough this fitness brings wealth and perhaps power with it, and is a very excellent form of self-protection. I am quite sure that, if the International Health Board of the Rockefeller Foundation had not the word "Health" in its title, its manifold activities would never have been received with complacency and gratitude by countries not owing allegiance to the Stars and Stripes.

It is true that, in certain directions, organized religion has played a part comparable to that of hygiene in moulding man's destinies, though it is also true that at times it has been the bitter foe of progress and enlightenment. Christianity throughout the dark Middle Ages kept alight here and there the torch of knowledge. We recall the stimulus to thought and inquiry engendered by the Reformation in Europe, but, as a rule, when it has signally influenced progress the effect has been due rather to a spiritual movement as, for example, the awakening of a spirit of sympathy with the sick and, as Dr. Welch has pointed out, the development of that new humanity which paved the way for the work of the sanitary reformers in England, rather than any deliberate campaign by a religious body. Religious organizations were in being in various parts of the world for many hundreds or thousands of years without any serious attention being paid towards the betterment of life and working conditions. It is true that Judaism, the creed of Mohammed, and certain other faiths did lay stress on the practice of preventive medicine, but it seems to me that none can equal in this or other fields what hygiene has accomplished in a remarkably short space of time, achievements which have wrought amazing changes in many parts of the globe and brought about a veritable revolution. It is too much to expect that organized religion could conquer disease: that is not its

province. The ancient faith of China did nothing to alleviate the myriad plagues of that vast territory; all the creeds of India—amongst them Buddhism, which possesses much that is attractive—failed to show how cholera could be mastered and malaria subdued. Christianity, with all its virtues, for hundreds of years coexisted with a great burden of communicable maladies. It was not until, in the fullness of time, scientific knowledge was applied to the prevention of disease that we gained our freedom from the fear of small-pox and of typhus and that you Americans were able to sweep yellow fever out of the New World.

The old, wise Greeks knew what they were about when they worshipped the goddess Hygeia and made her votive offerings. I am inclined to think that in some countries, such as India, hygiene will never exercise its full sway unless it comes to the people in the form of a religion, a new revelation to save and succour a vast multitude, the prey of superstition and disease. I believe that to-day you are opening and consecrating not a school only but a temple, a shrine with infinite possibilities.

Leaving the ancients out of the question and pioneers like Mead and Jenner, the credit for initiating the campaign which has had such remarkable results is due neither to the votaries of religion nor those of medicine, for it was a layman and a lawyer, Edwin Chadwick, who devoted all his time and gifts and energies to the realization of this ideal. Similarly in the United States it was Lemuel Shattuck, who was neither a divine nor a physician, but a student of social problems, who played the part of a pioneer.

There are, I think, three other factors which may be termed "world forces," and with which hygiene may, nay must, be compared: the pursuit of pleasure, the pursuit of wealth, and the pursuit of knowledge. All these, though in very different ways, have exerted a great influence on man and his affairs. No one, however, would place either the pursuit of pleasure or the pursuit of wealth in the same class with hygiene as a controlling force in human destiny. The influence of both is evanescent compared with that of hygiene, and too often is not in the direction of progress and true comfort. The pursuit of knowledge is in a different category. It has been a great and cardinal force, and might well contend with hygiene as a benefactor of mankind were it not that the art and science of hygiene have arisen from this pursuit and that hygiene, being the application of knowledge to man's needs, has outstripped it. The pursuit of food, at the call of hunger, has from the beginning been a world force, but, inasmuch as it is, in certain directions, a hygienic activity, it need scarcely come into our comparative list.

#### *World Hygiene To-day.*

And now let us see how, at the present time, hygiene acts as a world force. It does so in various ways. One is by the great system of quarantine, with its stations scattered over the globe and its control of ships and shipping. It is of interest to note that the first Quarantine Act was passed by the General Assembly of Pennsylvania in 1700, and was quaintly entitled "An Act to prevent sickly vessels coming into this Government." Hygiene has always had a close association with the sea and ships. It has abolished two great sea scourges, scurvy and ship beri-beri; it has radically changed life afloat, so far as navies are concerned; and now, at long last, it has commenced to take the merchant seamen under its wing. In this respect I must sorrowfully confess that the American mercantile marine is ahead of that of Great Britain. Speaking generally, you house and feed your sailors better than we do. This is a reproach we, an old seafaring nation, are now taking steps to wipe out, and if only the control can pass from the Board of Trade to the Ministry of Health, much may be accomplished.

Most unprejudiced persons will, I think, admit that, taken all in all, the British Empire has been a power for good in the world; and its sons, throughout the long years, have done much to make hygiene a world force. The traditions of the homeland have been carried overseas, and some of the great dominions, favoured perhaps by

local conditions, have, in certain directions, progressed further than the mother country. New Zealand has the lowest infantile mortality in the world; Australia has probably the most complete and best organized quarantine system on the face of the globe; South Africa has done more to prevent and stamp out disease amongst miners than has any other land; Canada, closely in touch with the vast public health developments in the United States, has in some ways more than held its own. For example, I believe the milk supply of Toronto, under the fostering care of Dr. Charles Hastings, will compare favourably with that of any other city. The Indian Empire, with its fine record of research in tropical medicine and hygiene—a record reaching back more than a century and containing the crowning triumph of Sir Ronald Ross, based on the reasoning of Sir Patrick Manson—has, it is true, failed to apply, as it might have done, all the lessons that research has taught, but its task is a stupendous one. It is something to have furnished great cities like Calcutta and Bombay with active sanitary organizations, to hold cholera in check, to grapple successfully with leprosy, to indicate the method whereby kala-azar may be controlled, to rob enteric fever of its terrors, to alter the whole outlook as regards amoebic dysentery and liver abscess, to cope manfully with the grim spectre of famine. In Malaya Sir Malcolm Watson and others have accomplished a great work in reducing malaria and rendering estate labour healthy. Hong-Kong has changed from a pestiferous hole to a comparatively healthy seaport. Singapore and Colombo have carried out important sewage and water works and taken elaborate steps to guard themselves against imported infection. In Palestine a revolution has been effected since the war, and there is not a single branch of public health which has not received some attention there at the hands of a small but devoted band of workers. The east coast of Africa, from Uganda and Kenya in the north to the Rhodesias in the south, has been the scene of active operations, and I would cite especially the campaign against syphilis in Uganda, that against yaws in Kenya, the war on the tsetse fly in Tanganyika, and the determined attack on malaria and blackwater fever in Southern Rhodesia. On the west coast, once the white man's grave, a great change has taken place, and, although there is much yet to be accomplished, notably in the case of yellow fever, where valuable help is being rendered by American experts, life is now very different, both for the white man and the black, all the way from the Gambia to Southern Nigeria, than it was when that intrepid woman Mary Kingsley sent out her clarion call for action. There remains the Anglo-Egyptian Sudan, a greatly changed territory now from what it was in the days of the Mahdi and the Khalifa. Turning to the New World, the British record is not so good, but we can point with some satisfaction to important advances in British Guiana and with a reasonable pride to what has been done in Port of Spain, while here and there elsewhere the torch of hygiene has been kept alight, even if it glows but dimly.

France, ever to the fore in questions scientific, has greatly ameliorated conditions in the vast territories under the tricolour. Her work on malaria in Northern Africa has been remarkable, in French equatorial sleeping sickness has been relentlessly pursued, in Madagascar plague has been combated to good effect, while in French Indo-China much has been done in the way of safeguarding the public health. The Dutch, with a passion for cleanliness bred in their bones, have displayed qualities of great thoroughness and persistence in coping with difficult situations in Java and Sumatra. The way they have tackled plague is an example for other countries to follow; they have solved important problems relating to the manufacture of vaccine lymph in the tropics; and, recognizing that hygiene pays, and pays handsomely, they have spent great sums in improving the housing and living conditions of the coolies on their fine rubber and cinchona estates.

The Germans have been shorn of their overseas possessions, but German influence and work continue to keep hygiene a world force and to increase its efficiency, more especially perhaps by shedding fresh light on the various sciences upon which hygiene and sanitation are securely

based. Belgium is busy, both at home, where her campaign against venereal diseases attracts special attention, and in that vast Congo region, so long inaccessible and full of terror for the white man, now a country where much scientific work is being carried out on preventive lines, notably in the case of sleeping sickness and tuberculosis. Italy, where the revival of learning had its birth, has contributed greatly towards the common cause. The early work there on malaria has had its repercussion in many parts of the world, and, in such colonies as she possesses, Italy does not forget Emerson's maxim, "The first wealth is health." Other examples from the Old World might be cited, for the activities of Japan have not been confined to the Archipelago of the Far East, and Japan can certainly claim a place in disseminating the principles and practice of hygiene; but it is time to cross the Atlantic or Pacific and see where America stands.

I said little in the way of comparing war and hygiene. In many respects they are as the poles apart, but let it not be forgotten that war has its constructive as well as its destructive side. There is no doubt hygiene is the greater and more beneficent force, but some of the most valuable advances in hygiene may be traced to war. Consider how campaign after campaign in Europe combined to give us the wisdom of that great army physician Sir John Pringle.

Moreover, it was war—war with Spain—which led the United States to spread abroad the knowledge and experience of public health measures it had gained and garnered since the days of Shattuck, to plunge into research with a view to prevention, to embark upon a policy which has had far-reaching results. Reed and his colleagues in Cuba penetrated the mystery which had shrouded yellow fever for centuries and Gorgas applied the new knowledge. In the Philippines and Porto Rico a hopeful gospel was preached and hygiene became a factor of paramount importance. Then followed Panama with all its wonders and triumphs, and now the good work has been extended to Haiti.

#### *Wealth in the Service of Health.*

With a few exceptions, all the cases I have cited are examples of countries busy in their own possessions, sometimes forced by circumstances to support the cause of hygiene, sometimes wise enough to see that such support is profitable, sometimes, no doubt, influenced by feelings of compassion and a desire to do the right thing.

But hygiene has been given an opportunity of showing itself as a world force in quite another manner, and this is perhaps the most startling and interesting and impressive development mankind has ever witnessed. Never before has altruism played such a part in hygienic progress, for never before has colossal wealth been turned to so beneficent an object.

When John D. Rockefeller placed his millions at the disposal of the International Health Board of the Foundation bearing his name he made that Board a power for good, a world power with amazing possibilities before it. Some of the possibilities have already been realized. Yellow fever, the scourge of tropical America, which formerly took terrible toll on your eastern seaboard, has been wellnigh exterminated. It has also been attacked in West Africa, and there is more than a reasonable hope that in the next few years it will be extinct. Even if it is not blotted out for ever, it has been so reduced and controlled as no longer to be an international danger. Again, take the hookworm campaigns set on foot in various parts of the globe; not so dramatic as the yellow fever work, but far more extensive. The war on the ankylostomo has already worked wonders in certain places, and, if only properly followed up, will make an enormous difference to labour in the tropics, and incidentally will greatly diminish the evils of soil pollution.

I have no time to tell of all the other ways in which the International Health Board is proving hygiene to be a world force of the first magnitude. Were I to enlarge upon the subject I would have to ignore another international organization which is also demonstrating in a remarkable manner how hygiene may sway the destinies of nations and be a power for peace. I refer to the Health

Organization of the League of Nations, the Health Section of which, under the guidance of its restless, enterprising, and far-seeing medical director, Dr. Rajchman, is becoming a friendly, if comparatively humble, rival of the International Health Board, and is extending its activities far and wide. The parent organization is now a very important body which certainly looks upon hygiene from the widest aspect and seeks to increase its scope and intensify its undertakings. This it does by means of its Advisory Council, represented by the Permanent Committee of the Office International d'Hygiène Publique at Paris, a committee on which both Great Britain and the United States are represented, its Health Committee with its various Commissions, and its Health Section. When one looks through the long list of their activities one recognizes, not only how much is being done, but how much has yet to be accomplished. Surely, however, the outlook is hopeful with powerful organizations on either side of the Atlantic exemplifying a new spirit of international co-operation and control.

It would take hours to recount the triumphs of hygiene, but, viewing them all, let us render thanks in this country to the men who have fought the good fight and seen the works of their hands established upon them. And what of the future? These men had not the facilities you are providing for the students of to-day. They had no schools of hygiene, in large measure they had to learn the lesson in that best of all schools, the school of experience. Yet it cannot be doubted that your young men will now start upon their careers better equipped than were their predecessors. Their enthusiasm can be aroused, their imaginations quickened by what they hear and do in this new school at Baltimore, and the very sight of a magnificent building devoted wholly to the teaching of preventive medicine should impress upon them the importance of safeguarding the public health, should convince them that hygiene is indeed a world force.

## Reports of Societies.

### RUPTURE OF THE BLADDER DURING PREGNANCY.

At a meeting of the North of England Obstetrical and Gynaecological Society, held in Liverpool on October 15th, with the President, Mr. W. GOUCH (Leeds), in the chair, Miss HELEN M. DUVALL (Liverpool), on behalf of Professor E. E. GLYNN and herself, reported a case of rupture of the bladder during labour, with fatal peritonitis. Miss Duvall said that the clinical details of the case were as follows.

The patient was a primigravida, aged 29, who had been a regular attendant at the ante-natal clinic attached to the hospital during her pregnancy. Her pelvic measurements were normal, and the urine, which had been tested weekly for some time, had no abnormal constituents. On admission she was at full term, the os was one fingerbreadth dilated, the head well down in the pelvis, and the presentation left occipito-anterior.

During the next three days she had intermittent labour pains, and the membranes ruptured at 6 p.m. on the fourth day, the os being three-quarters dilated at 8 p.m. At 3 o'clock on the following morning the patient is said to have given a piercing shriek, and to have complained of acute abdominal pain. The nurse felt the uterus then, and there was no contraction, but the patient was rather cold and clammy, and became somewhat hysterical. As the labour had been long, and the interest of the child seemed to demand it, low forceps were applied under chloroform, and the patient was easily delivered of a living male child weighing 6 lb. 5 oz. A perineal tear of the second degree occurred, and was repaired. The third stage occupied an hour and a half, and the placenta and membranes were delivered by manual expression. The condition of the patient was then considered satisfactory. The patient passed urine voluntarily just before the anaesthetic, and no urine was obtained on the passage of a rubber catheter before the application of forceps. Apparently the patient's condition gave rise to no anxiety during the next twenty-four hours, but as she passed no urine during that time she was catheterized, and 8 oz. of "smoky" urine (said to contain no blood or albumin) withdrawn. On the following day she passed 8 oz. voluntarily at 2 a.m., and 6 oz. again at 2 p.m. By the evening she had become very ill, complexion sallow, temperature 100.2° F., pulse rapid and almost imperceptible, respirations quickened. The abdomen was much distended and very tympanitic, and there was pain in the left iliac region. The usual restoratives were given, but she was much worse by the next morning, with

a frequent brownish-green vomit and incontinence of faeces. She died at 10.55 a.m., three days and five hours after delivery.

At the *post-mortem* examination, seven hours after death, the subcutaneous fat of the abdominal wall was found to be fully three to four inches thick, which must have made accurate diagnosis of the abdominal condition during life extremely difficult. The peritoneal cavity contained about six pints of a turbid and slightly blood-stained fluid, smelling strongly of urine, and containing large flakes of recent fibrin. The intestines were distended to about double their normal size, and the peritoneal coat injected. A small oval perforation, which would just admit the points of a Spencer-Wells forceps, and the edges of which were gangrenous, was discovered on the posterior surface of the bladder, about midway between the fundus and the utero-vesical reflection, and half an inch from the mid-line. Radiating from the hole were three rents, involving the serous and muscular coats, but not the mucous membrane. On slitting open the bladder from the front, the perforation was seen to be surrounded by an area containing numerous small haemorrhages. Apart from this the lining epithelium appeared to be normal, as were also the ureters and their orifices. The kidneys and other organs showed no evidence of disease. The uterus was uninjured, except for a deep right-sided cervical tear. The cause of death in this case was undoubtedly rupture of the bladder followed by peritonitis.

Miss Duvall said that this type of accident must be very unusual, as after a good deal of search she had only found two cases recorded, in which intraperitoneal rupture occurred actually during the course of full-term labour. The first of these was a Liverpool case, reported to this society at Manchester in 1905 by Dr. Grimsdale, and afterwards published in the *Journal of Obstetrics and Gynaecology*, vol. vi, 1, p. 354. The second was in 1908 by C. P. Porter in the *Transactions of the Obstetrical Society of London*, vol. 49, p. 171. Both these cases presented many similar features to this one—namely, the patients were primigravidae with no pelvic contraction and no definite history of urinary disease. Both had instrumental deliveries, and in both the rupture was situated, as in the case reported by Miss Duvall, on the postero-superior wall of the bladder; it was considered by the authors to have been spontaneous, and to have occurred prior to the application of forceps. In Miss Duvall's case there was no clinical evidence of pre-existing urinary disease, and the naked eye and microscopical examination of the urinary organs was in accordance with the history. With the exception of the bruised area around the perforation, the lining of the bladder appeared normal. Professor Glynn considered at the *post-mortem* examination that the wall, however, was somewhat thinner than normal. The thickness of the muscular and mucous coats empty measured just over 2 mm.; the normal measurement was 6.3 mm. Had there been cystitis it would have been visible in the trigonal area, which was obviously quite free from disease. The microscopical section taken from the uninjured portion of the bladder showed no pathological condition except some congestion of the submucous vessels; the absence of epithelium could not be adduced as evidence of disease, and had occurred in a control specimen subjected to similar *post-mortem* conditions and methods of preparation. The section taken from the bruised area simply showed a recent extravasation of blood throughout all the layers; it was, in fact, the picture of a bruise. The muscle was not diseased, and there was no inflammation. The situation of the lesion made direct injury by the forceps unlikely. In a primigravida, at any rate, this portion of the bladder would have been in the abdomen. The presence of distension at any time during the labour was not shown in the history, but the first stage was prolonged, and the patient might not have been properly emptying the bladder throughout. She was so fat that distension, if present, would not have been observed. Evidence of the time of rupture was afforded by the gangrenous edges of the perforation and the degree of peritonitis found at the *post-mortem* examination. In view of the fact that the urine was certainly not grossly infected, acute peritonitis would not follow very soon after the rupture. The chart was also consistent with an ingravescent sepsis. The amount of urine obtained after delivery was only 22 oz. in three days. A curious point was the ability shown by the patient on two and possibly three occasions to pass urine voluntarily, presumably after rupture; but in view of the very small leak this was not to be considered an impossibility. Lastly, there was the history of the cry uttered by the patient three hours before delivery, followed by the complaint of acute abdominal pain. All these facts seemed to point to the

rupture having occurred prior to or at the time of delivery, the cause being increased intra-abdominal pressure due to the pains of labour on a bladder probably overdistended, and therefore weakened, but certainly not otherwise diseased.

#### *An Eight Months' Abdominal Pregnancy.*

Dr. J. W. A. HUNTER (Manchester) gave an account of a case of abdominal pregnancy which lasted eight months. The clinical history was as follows.

A married woman, aged 30, was admitted to hospital on August 23rd. Her last menstrual period had been on March 16th, and was followed by several weeks of irregular bleeding for which she was curetted, a diagnosis of incomplete abortion having been made. After curettage the bleeding ceased, and she was sent home, but shortly afterwards she noticed a gradual increase in the size of the abdomen. About the beginning of July she had a sudden attack of acute pain in the abdomen with sudden enlargement of the swelling, and accompanying the pain were recurrent attacks of vomiting and faintness. During the six weeks before admission there was progressive abdominal enlargement, with increasing tenderness and recurrent attacks of severe abdominal pain, often accompanied by vomiting. Six days before admission there was slight loss of blood from the vagina. Beyond these, increasing frequency of micturition and gradually increasing constipation were the only symptoms of which she complained. On admission she was rather pale, collapsed, and obviously in considerable pain. Her pulse was small and rapid, the rate varying between 120 and 140; temperature 100°. The abdomen was enlarged to the size of an eight months' pregnancy, the tumour extending almost to the ensiform cartilage. The swelling tended to occupy more the left side of the abdomen than the right, and was hard, rather fixed, and extremely tender, the whole picture closely resembling that of a concealed accidental haemorrhage. It was possible to elicit fluctuation in the upper left portion, but the mass in the right iliac fossa was quite hard and solid. There was no dullness in the flanks, and no foetal heart sounds or movements could be detected. Vaginal examination was unsatisfactory on account of the extreme pain and tenderness, but suggested a firm mass continuous with the cervix occupying the lower right quadrant of the abdomen, and a large cystic mass inseparable from it above and to the left. The diagnosis lay between concealed accidental haemorrhage and a twisted ovarian cyst complicating early pregnancy. The possibility of an abdominal pregnancy was considered, but rather discounted in view of the previous curettage and absence of other signs. The patient was kept under observation for twenty-four hours, but did not improve, in fact became rather worse, and an operation was then decided upon, a diagnosis of twisted ovarian cyst complicating early pregnancy having been made.

On opening the abdomen a large rather thick walled cyst was seen almost filling the peritoneal cavity; the latter also contained a large amount of recent fluid blood and old blood clot. On extending the incision the "cyst" was seen to be rising from the left broad ligament, which had been stretched and lifted up, the size of a three months' abdominal wall in front and to the omentum and small intestine above and behind; during this separation the anterior wall suddenly gave way and a large quantity of liquor, followed by a living child, came out. The gestation sac was then seen to be composed of a much stretched out broad ligament anteriorly, while posteriorly it had burrowed under and lifted up the caecum and mesentery of the small intestine; the right colic artery was running in the wall of the sac. The placenta was hurriedly removed, and the sac packed with gauze and marsupialized. During removal of the placenta there was very little bleeding, but there was considerable haemorrhage in the abdominal cavity, probably from a torn branch of the right colic artery. After operation the patient was very collapsed and failed to respond to treatment, dying shortly after return to the ward. The child, weighing 2½ lb., was quite normal and lived for fourteen days.

Dr. Hunter said that the case presented several unusual features. On looking over the history it appeared certain that the so-called incomplete abortion for which she was curetted was in reality an early ectopic gestation, and very possibly rupture of the sac into the left broad ligament occurred during this manipulation. Secondly, the associated hydramnios almost excused the mistake in diagnosis, for even when the cyst was exposed it was impossible to palpate the foetus through its walls. To avoid a fatal result was very difficult in view of the manner in which the "sac" had displaced the mesentery and bowel, and even if the patient had recovered from the operation, intestinal obstruction would have almost inevitably ensued. It was possible that incision of the sac, emptying the contents, and packing it immediately, instead of an attempt to free it from the surrounding adhesions, would have given the one chance of a successful result.

#### *Malignant Disease Associated with Genital Prolapse.*

Dr. J. W. BRIDE (Manchester) described two cases of malignancy in association with genital prolapse, the first being a case of cervical carcinoma with vulval epithelioma

and the second one of primary carcinoma with prolapse of the uterus.

The first patient, aged 50, had six children, the last ten years ago. Menstruation had been 4/28 type and profuse, the last two months ago. In June, 1921, she complained of a brownish watery discharge and of "something coming down." She had never worn a ring pessary. She was found to have a complete prolapse with hypertrophy and severe ulceration of the cervix. Although the cervix was not considered definitely malignant the uterus was removed by vaginal hysterectomy in the course of an extensive anterior colporrhaphy according to Fothergill's method. The pathologist's report was that there was a columnar-celled carcinoma of the cervix. The patient made an uninterrupted recovery, and until April, 1925, four years later, she had no further trouble. At this date there was no sign of any recurrence of growth in the pelvis, but she was complaining of a small ulcer on the right labium majus, obviously epitheliomatous and fixed. She first noticed irritation and then ulceration in December, 1924. The vulva and glands were excised, and microscopical examination showed it to be a case of epithelioma of the vulva. Recurrence followed at the end of that year, and radium was applied on two occasions. The patient died in 1926. There was never any recurrence due to the cervical condition.

Dr. Bride said that it appeared to be generally allowed that malignancy of the cervix was rare in association with genital prolapse. Cullen regarded the incidence of the two conditions as accidental, and did not consider that prolapse predisposed to carcinoma. Pantow, who reviewed the literature in 1893, found only twenty-nine cases, in all of which the prolapse preceded the carcinoma. The unlikelihood of there being any connexion between the primary columnar-celled carcinoma of the cervix and the vulval epithelioma was important. This case seemed to illustrate the point that vaginal hysterectomy might still be regarded as holding out almost as good hope of cure as the abdominal total extirpation.

Dr. Bride's second patient was married, and had four children, the eldest being 29, the youngest 23 years of age. All the labours were normal, but she had noticed "something coming down" since the birth of the first child. For the last five to six years this had been getting much worse, and she had worn a rubber ring pessary. Menstruation had ceased eleven years ago, but three years ago she had a profuse attack of bleeding for three weeks, and had a slight brownish discharge at times since. In June, 1926, she had, against advice, retained her rubber ring pessary, No. 3, for ten months. On removing it, in a very offensive condition, a large raised bleeding plaque was found on the lower middle part of the posterior vaginal wall, and epithelioma of the vagina was diagnosed. The growth was an oval plaque with raised hard edges and crater-like centre, about 2 inches long by 1½ inches wide. It appeared to be fixed to the rectum, probably inoperable, and best treated by radium. However, being anxious for a section of it, Dr. Bride performed posterior colporrhaphy, including the growth in the flap; it was dissected off the rectum with great difficulty though it was right on to the rectal mucosa. Previously to this the uterus was curetted, and so malignant disease of the body or cervix was found. The growth was a primary squamous-celled carcinoma of the vagina. The patient was discharged, and before leaving hospital radium was applied.

Dr. Bride said that Dougal at Liverpool, in 1922, had described a case of primary carcinoma of the posterior vaginal wall treated by hysterovaginectomy, where the growth occupied the upper two-thirds of the wall. In summarizing the literature Dougal mentioned that Meyer, Schmit, and Winckel had each described a case possibly due to pessary irritation. It seemed possible that Dr. Bride's case might have originated from the same source, since the patient neglected to have the pessary removed and cleaned at proper intervals, as instructed. For a growth situated in the lower part of the vagina, possibly this very simple operation together with radium might effect a cure.

#### Malignant Growths in the Cervix.

Professor W. BLAIR BELL described a case of bilateral squamous-celled carcinoma of the ovaries and peritoneum. The patient was a nullipara, aged 55, who, five months previously, had undergone vaginal hysterectomy for cancer of the cervix. A very large tumour was found occupying the whole of the right side of the abdomen from just below the ribs to the symphysis, and free fluid was present. Bilateral, partly cystic and partly soft, solid tumours were removed; the left one was adherent to the bladder. Nodules of growth were discovered in the pelvis at the vault of the vagina, and metastases were observed in the liver. The tumour consisted of malignant cells derived from squamous epithelium, and there was much necrosis with softening. Comment was made on the extreme rarity of such tumours

in the ovary. Professor Blair Bell also described a case of squamous-celled carcinoma of the ovaries and peritoneum subsequent to carcinoma of the cervix in a widow, aged 62, treated by radium. The pelvis was occupied by squamous-celled carcinomatous growths of the ovaries. Nodules and masses were present in the peritoneum and the omentum. This appeared to be a case of cervical cancer cured by radium, but growth of a similar character subsequently developed in the ovaries, and from them disseminated in the peritoneal cavity.

The PRESIDENT emphasized the rarity of malignant growths of the ovaries secondary to carcinoma of the cervix, though not in the case of carcinoma of the body. Dr. LEITH MURRAY thought that the growths might be columnar-celled rather than squamous-celled carcinomata. Professor BRIGGS agreed with this suggestion, and it was decided to refer the matter to a pathological subcommittee.

Dr. C. P. BRETNALL (Manchester) showed slides illustrating endometrioma of the anterior abdominal wall; and Dr. H. LEITH MURRAY (Liverpool) demonstrated a specimen of primary carcinoma in the appendix removed from a patient aged 42.

#### THE EFFECT OF LIGHT ON THE SKIN AND SKIN DISEASES.

At the meeting of the Section of Dermatology of the Royal Society of Medicine on October 21st, with Dr. J. H. SEQUEIRA in the chair, a lecture, well illustrated by the epidiascope, was delivered by Dr. C. RASCH (professor of dermatology and venereal diseases, Copenhagen), on the effect of light on the skin and skin diseases.

Professor Rasch began by objecting to the pronouncement of a certain physiologist—that clinical medicine was a played-out science, and that the only use now was for experimenters. He contended that clinical science and experimentation were the twin supports of modern medicine. Turning to his subject, he said that priority in studying the effects of light on the skin must be given to Sir Everard Home (1763-1832), who had conducted experiments showing that irritation caused in the skin by the sun was due to its light, not to its heat, as also was the pigmentation function. One effect of the sun on morbidly sensitive skin was to produce a condition which Professor Rasch had previously described as an eczema-like polymorphous light eruption. The rash itched intensely, and consisted of slightly raised erythematous spots, oval or round in shape, varying in size, partly vesicles and partly scab-covered papules. In 1911 Dr. J. H. Sequeira had described a disease which he called permanent freckles, for which light was held responsible. It consisted of a steadily increasing outbreak of spots of pigment, as in xeroderma pigmentosum, but lacking the other signs of this latter disease. The manifestations of skin reaction to light varied with each individual, the itching being followed sometimes by papular lesions, or erythematous or urticarial lesions, often with diffuse weeping on the surface. There might be secondary infections with impetigo or folliculitis. He agreed with Dr. H. G. Adamson that there existed a relationship between the milder cases of summer eruption and Bazin's hydroa vacciniforme. There should be a distinction between this latter condition and the polymorphous light rash. Polymorphinuria was not always associated with this sensitiveness to light, but it seemed to act as a sensitizer to the skin, as did also alcohol. The lecturer showed a photograph of an extensive ulceration on the hands of an alcoholic who had slept in the sunshine in a park; it was a bullous rash, like the "pseudo-pellagra" of the French. He also described two cases of war melanosis due to the action of light, and two cases of colloid degeneration of the skin owing to the same cause. The chronic reddening and thickening of the skin in old peasants was a common observation, and he attributed it to the continual effect of the sun's rays. Allied to this condition was a senile degeneration of the elastic tissue of the skin. It was an old observation that the lesions of small-pox healed without leaving scars when the patient was kept in the dark. A "red room" ought to be installed wherever small-pox was treated. Pityriasis simplex was sometimes rendered eczematous by the action of light. Lupus erythematosus

was decidedly aggravated—indeed, was often produced—by light. Light also aggravated dermatitis herpetiformis, Besnier's prurigo, psoriasis, purpura, and erythema multiforme. On the other hand, there were not many skin diseases which were actually improved by natural light. Even lupus vulgaris was not appreciably influenced by the local action of light, the effect in this case being caused by cauterization and burning, with a mixture of heat rays and concentrated light rays. The universal light bath often had a good effect in this disease. Skin affections which usually benefited by light were acne vulgaris, the secondary syphilitic affections of the skin, elephantiasis, and lichen planus. Sometimes direct light prevented a papular syphilitic lesion from developing. In conclusion, Dr. Rasch said that the reason there were so many harmful effects due to light was that many held the view that as much light as possible was good for all people and for all diseases.

#### Clinical Cases.

Preceding this lecture a number of clinical cases were shown to the Section, including one by Dr. HALDIN DAVIS, entitled "Pigmentation of unknown origin," and another, by the same exhibitor, under the name of "argyria." This second case of pigmentation, Dr. Davis said, was due to the ingestion of silver nitrate pills, at one time a fashionable remedy for indigestion. This woman took these pills three times daily for a period of twelve months twenty years ago, and she had suffered from argyria ever since that date; the discoloration had only become slightly fainter. Argyria seemed to be very capricious in its incidence. One woman, after only six weeks' use of protargol in the form of swabs for uterine trouble, had this same characteristic pigmentation, but it disappeared after lasting three years. He was still unaware of the origin of the pigmentation in the case first referred to. Civette called an apparently similar case poikiloderma reticularis, and stated that there was atrophy of the skin. No atrophy had been noted in the case now shown; there had been menstrual troubles for six or seven years.

Dr. GRAHAM LITTLE showed a patient who, when he came before the Section in May last, had a serious condition of acute nodular leprosy. So serious was the condition that the patient was urged to return to India as speedily as possible. But he came under Dr. Hasson's care, and two months later that gentleman asked Dr. Little if he would like to see him again. He did so, and found, to his astonishment, that the disease had become completely involuted, and no lepra bacilli could be found in the mucosa of the nose or in blisters artificially caused in the anaesthetic areas. Searches for the bacilli since the great clinical improvement of the patient had consistently failed. Dr. Hasson briefly spoke on the case, remarking that he found the use of chaulmoogra oil useless in this disease, and in 1923 commenced giving his patients a special vaccine, which was not autogenous, but a stock vaccine, the patient being blistered in order to carry out the technique. This patient had had fifty-three injections of the vaccine, some into the veins, the remainder under the skin. He hesitated to apply to this case the term "cured," as a relapse might occur up to five years, but certainly all signs of leprosy had now disappeared.

### SURGERY AND THE WORKMEN'S COMPENSATION ACT.

IN the Section of Surgery of the Royal Society of Medicine on October 20th Mr. V. WARREN LOW, the incoming President, delivered his address from the chair, which was followed by a discussion. He took as his subject "Surgery and the Workmen's Compensation Act."

Mr. Warren Low began by tracing the history of workmen's compensation. As far back as 1846 a Select Committee, shocked by the casualties occurring among labourers engaged in railway construction, reported in favour of making the railway companies pay compensation in cases of accident, but it was not until 1880, and then only tentatively, that steps were taken by the Legislature to give effect to that salutary suggestion. In 1880 the Employers' Liability Act was passed. Previously the only remedy for the workman was to bring a common law action

against his employer, in which he had to show that the injury arose through the employer's personal negligence or through his having knowingly employed an incompetent servant. Furthermore, the counter-charge of contributory negligence might, if substantiated, deprive the workman of success in his action. In 1897 the Workmen's Compensation Act introduced into English law the entirely new principle that the workman was entitled to compensation irrespective of any question of negligence, but that statute applied only to certain dangerous trades. In 1900 the Act was extended to agriculture, and in 1906 to all employments with some specified exceptions. The innovation of greatest interest in this last measure was the provision that the county court judge should have a medical referee sitting with him as assessor. In 1919 a departmental committee was appointed, and as a result of its report the Act of 1923 was passed. This was repealed in large measure, and the Act of 1906 was wholly repealed, by the new consolidating Act of 1925.

Owing to the number of cases which had been decided in the courts and to the medical knowledge now available, the legal position of any plaintiff, save in a few exceptional cases, was perfectly clear provided the facts were proved. To the legal mind, untrained in medicine, it must often appear that opposing doctors were expressing quite contradictory views, not to be explained by the ordinary and legitimate differences of professional opinion. The difference, however, was more apparent than real. In this class of cases there was plenty of room for wide differences with regard to the essential points at issue. The duration of incapacity, for instance, was a matter upon which there might be quite different views, and it was often most difficult for the conscientious surgeon to decide after what period the injured workman ought to be forced to resume his normal employment. A number of cases were found in which a few weeks of incapacity created a workshyness and an inertia which was exceedingly difficult to overcome, and the certifying doctor might shrink for months from applying the drastic remedy of refusing a certificate. It would be difficult to assess the loss to industry which ensued from this prolongation of the period of supposed incapacity, and perhaps even more serious was the effect upon the man's morale. With a little more encouragement and persuasion the time of incapacity might be materially diminished.

Of all the pitfalls those which arose in connexion with diseases of the nervous system were possibly the most treacherous. Mr. Warren Low gave details of typical cases in some of which, for example, commencing general paralysis or other syphilitic affection of the central nervous system was accelerated or aggravated by an injury. He had notes of several cases in which a trivial injury was held to give rise to symptoms which were really due to the insidious onset of cerebral tumour. The possibility of a typical neurasthenia or psychasthenia following an injury had to be admitted. In these cases the distinction between a pathological condition and a certain type of malingering was very difficult. Often in cases in which neurasthenia ensued upon a trivial accident it seemed to efface from the individual not only all ambition but even self-respect, and he was content to live a life of semi-invalidism in which he could never quite be said to be malingering, but was certainly making the most of a very slight disability. Some of these people, once they were labelled neurasthenics, were content so to remain as long as the stimulus of want did not force them to make exertions. A large proportion of cases of surgical tuberculosis, particularly in the spine and joints, were associated with injury, and here again often the injury was an afterthought, so deeply rooted in the mind was the idea that disease must be caused by something exterior to the patient, and the thing easiest to recall was some, perhaps, slight injury no more than that which men in certain employments frequently sustained. It was quite impossible to lay down any general rule for dealing with these cases; each case must be considered by itself.

The difficulty was very great also in cases of osteoarthritis. Slight repeated injuries to joints might possibly induce this condition, but the first intimation of anything wrong with a joint often followed an injury. A man might

have been carrying on his customary work for some time without noticing, or others noticing, how stiff and awkward his movements were, but when an accident occurred which laid him up for a short time he often had singular difficulty in getting again into his stride. Mr. Warren Low gave many examples of the difficulties which a cunning or a stupid man might introduce into what should have been a straightforward case. Another very difficult question was the length of time which should elapse before a man who had sustained a fracture, particularly a fracture of the lower limb, might return to work. Many such men were put for years upon light work—mess waiters, lift attendants, and the like—which was of small economic value. Good anatomical results might be secured, and there might be no stiffness of joint when the man left the hospital; nevertheless, he would go limping about, making no attempt to continue the exercises he had been taught. The conditions of industry would seem to require, in addition to the use of ordinary hospitals, some after-care centres where, by constant supervision and encouragement, men who had been discharged from hospital might be induced to overcome their lack of faith in their own restored powers.

Dr. ERNEST SOLLY (Medical Referee, Harrogate) corroborated what the President had said about the difficulty in deciding between the disability definitely due to an accident and that due to other causes. One great deficiency in the Act was that it made no provision for the assistance of the medical assessor or referee by affording him reliable evidence, such as an x-ray photograph. He had twice applied to the Home Office on this matter, and had been told that in one case one guinea and in the other case two guineas could be expended for this purpose; this was not enough for a proper radiological report. The referee was called upon to give an opinion from which there was no appeal, and yet no definite provision was made for him to obtain the evidence by which alone he could make that opinion definite.

Dr. MURRAY LESLIE (Medical Referee, City of London) said that a radiograph was only one of several things which the medical referee ordinarily could not get. He agreed with the President's suggestion as to the need for industrial after-care centres. When the surgeon had done all that he could, when the Pott's fracture or the Colles's fracture had healed, when the punctured wounds had cleared up satisfactorily, and the man was sent out of hospital, he still remained in his own opinion and in the opinion of his friends not able to resume work, and the period of such incapacity might extend from one to five years. The determination of incapacity depended very much on the temperament and environment of the man himself and the character of his friends. A peculiar thing happened to the majority of these men. It was more than mental inertia, and the word that expressed it most clearly was "deterioration." The man's whole mental outlook worsened. This was partly the result of idleness, possibly lounging at the public-house, partly also the result of the commiseration of his friends, which led him to feel himself a victim and a hero, and his injury assumed an undue proportion in his mind. Treatment was required in many of these cases for the man's mind no less than for his limb.

Dr. D. A. COLES (Beckton) hoped that the next Workmen's Compensation Act would be less slipshod in its language. For example—the word "serious" was used—"serious and wilful misconduct of that workman," "serious and permanent disablement"—although neither a lawyer nor anyone else could define the term. He referred also to the unintelligibility of Section 9, in particular the rules for calculating the weekly payment in the case of partial incapacity. One thing to be deplored in all these cases of industrial accident was the usual absence of any careful note of the time and circumstances. Mr. MARYARD SMITH asked whether Mr. Warren Low had come across many cases of acute osteomyelitis. He had had two such cases in young persons following a very trivial injury, in one of them so trivial that no notice of it was given to the foreman at the time. Was it to be held that osteomyelitis was the direct result of an injury? He had also had a case which suggested that progressive muscular atrophy might follow an injury. He thought that

some care might be taken in the choice of referee with respect to the type of case. He had known a nerve specialist sitting as referee in a surgical case.

Dr. R. PROSSER WHITE (Wigan) said that there had been about 500 cases of mule-spinner's cancer in Lancashire, costing the masters about £100,000 in damages. These cases began with a papule, which enlarged, and then developed into a spindle-celled sarcoma. He wished to ask the surgeons at what stage this should be treated by operation. Following operations on the groin there had been some lymphatic stasis and lymphangitis, and the man operated on had never been able to return to his ordinary work. Was there a greater danger in removing glands from the groin than from the axilla?

Mr. MAX PAGE said that in his out-patient department he had been very much struck by the frequency with which epididymitis was attributed to a definite injury. The actual injury had nothing to do with the beginning of the infection, it simply called attention to the painful spot. He also drew attention to the industrial disability following fractures of the os calcis. These patients with impacted fracture were sent out of hospital still complaining of painful heel, and he wondered whether the men ever got back to work at all.

Mr. WARREN LOW, in replying, said that he could not help feeling that the profession had been a little slack in the matter of certification; to give a certificate that the man was not yet fit for work or fit only for light work was so often the path of least resistance. Light work was not economic labour, and there were thousands of men, otherwise able-bodied, employed on these jobs. He had not actually come across cases of osteomyelitis developing after injury; the condition was rare in adult life, though recurrent osteomyelitis was sometimes found in older people when the original organism had been introduced into the system during childhood. In reply to Dr. Prosser White, any extensive dissection of the lymphatics of the groin was very apt to lead to lymphatic blocking. In conclusion he urged that industry should take some steps by means of after-care to speed up the return of men to work. In America the Pennsylvania Railroad and other big industrial undertakings had their own hospitals and medical officers; when the patient reached the stage at which he would ordinarily be discharged from a public hospital he was taken in hand and trained and encouraged to fit himself for resuming his occupation.

### THE PHYSIQUE OF SCHOOLBOYS.

At a meeting of the Manchester Medical Society, on October 6th, Dr. ALFRED A. MUMFORD, medical officer to Manchester Grammar School, delivered his presidential address on the physique, stamina, and efficiency of schoolboys.

Dr. Mumford said that the Manchester Medical Society was founded in 1834 by a number of young medical men, many of whom had had ample experience of the ill effect of the factory system owing to their holding appointments at the numerous local hospitals and dispensaries. They had advocated Government inspection and control, signed petitions in its favour, and had given evidence before various parliamentary committees and commissioners. Sixteen out of the twenty elected as officers to the new society were associated as teachers with one or other of the local schools of medicine. That there was a general desire for the improvement of health in the district was shown by the fact that a board of health had long been established, and a few years later a sanitary association was started for instructing the public in general matters of health. There was good reason for believing that the activating spirit was James Kay Shuttleworth, who had already instigated the formation of the Manchester Statistical Society to inquire into problems concerning the degradation, ignorance, and disease of the town population. Problems similar to those aroused by employment of children in factories were naturally met when the national system of education compelled the attendance of children at school. Though the medical assessment of health had vastly improved during the last ninety years, yet the methods of

measuring physique advised by the medical witnesses during the Factory Commissions, the measuring rod, the scales, the tape and the pulmometer of Thackrah, and the date of eruption of the permanent teeth introduced by Sir E. Saunders, still constituted the basis of judgement of the physique of the schoolboy. In all calculations they must begin with the average boy, and from him measure the degree of accelerated or retarded physique, the effect of instruction in the gymnasium, swimming-bath, games, and classrooms; they had even extended their inquiries to the comparison of school physique with its sequel in the local university. The Manchester Grammar School measurements had been taken under exactly the same conditions from 1881 to the present time. They showed that the average boy was steadily improving in height, weight, and chest girth, though the measurement of vital capacity and of endurance (by Flack's test) was of too recent adoption for determining whether there was any improvement in respiratory power. Comparisons of boys admitted to the Classical Sixth and Science Sixth between 1890 and 1910, and of boys chosen for the gymnasium eights during the same period with the normal boy, showed that, while there was little to distinguish them in height or weight from the average boy, yet in both cases there was a significant difference between them and the normal boy as regards chest girth, which in both cases was superior. In order to find a common basis for comparing mental and physical progress some units of physical measurements must be taken and based on time increments—namely, in the progress made in six or twelve months. Tables of time increments in height, weight, chest girth, vital capacity, and endurance based upon the records at the school had been drawn up, and were used for constant reference. By means of these the relative development in the different categories could be compared. Observations were also made on the specific gravity of boys in the school swimming-bath during the summers of 1923-24. It was found that the largest factor in the variations was due to the degree of inflation and the size of the chest. When the means of the observations with inflated chest at each year of life were taken it was found that they were always below that of water, while the means of the observations with deflated chests were always above that of water. The question of buoyancy as a standard of health was therefore considered. As it was impossible to measure the buoyancy of all the boys in the swimming-bath, an attempt was made to utilize the measurements taken in the gymnasium for finding the relation between weight and volume—namely, the specific gravity.

The formula  $\frac{\text{Weight in grams} \times K}{\text{Height in cm.} \times (\text{chest in cm.})^2}$  was adopted.

A lengthy series of inquiries showed that for the average boy K was in the immediate neighbourhood of 19.5. In the subsequent 2,300 calculations of the series of measurements the K was left out and the formula  $\frac{W}{H \cdot C^2}$  was used as a "crude buoyancy index" of health. If special cases, where the chest girth differed markedly from the mean circumference of the body, as for example, the cases of boys of exceptional shoulder development and the case of boys of very full stomach, were left out, the crude buoyancy index was a very useful method of testing the physical fitness of different boys. The means of the crude buoyancy index of the 2,300 cases at each age were taken as the normal, and it was found that the high-level scholar was of markedly greater buoyancy and the gymnasium champion of still greater buoyancy than the average boy of the school. A further series of measurements of shoulder girth was taken, and this girth was calculated as a percentage of the trunk height in order to obtain an index of shoulder development. Dr. Mumford added that a study of the development of the shoulder in relation to physique was of very great importance, since in Circular 1363 the Board of Education had virtually scrapped the elastic horizontal ladder, the row of rings, the parallel bars and the horizontal bar, which had played so large a part in developing the physique, and courage of English public schoolboys, substituting Swedish apparatus for them. Mathematical analysis of measurements taken at the Manchester Grammar School showed a high correlation between

the development of the shoulder, as secured by English methods, and the high range of breathing; whether Swedish methods would prove as active and beneficial to English public schoolboys remained to be proved. Graphs illustrating the development of champion gymnasts, swimmers, winners in long-distance runs, sprinters, holders of school colours in lacrosse, football, and cricket, and also graphs showing differences in physique between boys of accelerated and boys of retarded scholarship, had been constructed and exhibited. Finally, a group had been taken of 140 students who, during the last ten years, had been educated at the Manchester Grammar School, where they had been submitted to periodic measurements and had subsequently passed on to the Manchester University. The group was divided into two sections: (1) about forty-five in number who had passed through a five years' course at the medical school and had not failed at any examination; and (2) those who had suffered one or more failures. It was found that though the mean height after 16 years of age in the former group had been slightly less than the mean of the latter group, yet when the relative gradings in height, weight, and chest girth were compared, the boys who had passed through the university without any failures had shown an ampler range of breathing or a larger chest girth in relation to their height than the group who had suffered failure.

### SCOTTISH SOCIETY OF ANAESTHETISTS.

#### *Annual Meeting.*

THE Scottish Society of Anaesthetists held its annual meeting in the Faculty Hall of the Royal Faculty of Physicians and Surgeons, St. Vincent Street, Glasgow, on July 6th last. The meeting was attended by the Associated Anaesthetists of the United States and Canada, who were then touring in this country; among those present were Dr. Mary E. Botsford of San Francisco, Dr. Wesley Bourne of Montreal, Dr. J. Wade Elphinstone of Pittsburg, Pa., Dr. R. B. Hammond of White Plains, New York, Dr. F. H. McMechan of Avon Lake, Ohio, and Drs. E. I. McKesson and Lamara Schuey of Toledo, Ohio.

Dr. J. STUART ROSS, who was succeeding Dr. A. Mills as president of the society, gave his presidential address on "The provision of an anaesthetic service." Dr. Ross explained the steps he had taken to ascertain what was being done at the various medical schools to improve the supply of skilled anaesthesia both in hospitals and in private practice. A questionnaire had been drawn up and circulated to leading anaesthetists. Replies had been received from a large number of schools in England and some of the Dominions. From the replies it appeared that lectures to students were universally provided and that attendance was obligatory. The number of attendances varied from three to a dozen. Dr. Ross thought they should always be more than six, and should include instruction in applied physiology. In many schools the subject was illustrated by demonstrations upon anaesthetized animals, whereby the causes of various accidents which might happen in the operating theatre were made more clear to the student mind. In the supervision of students in practical administration emphasis should be laid upon the use of safe methods for minor surgery and for dentistry. Owing to the deficient teaching of the medical student in Scotland the Edinburgh Dental School had educated its pupils to give their own anaesthetics. In over sixty thousand administrations at the Edinburgh Dental Hospital there had not been a fatality. Special instruction in anaesthetics should always be given to residents immediately on or before taking up office. This was evidently generally recognized; but some schools which had resident anaesthetist appointments naturally did not need to give extra teaching to the other house officers. Post-graduate instruction was now available, particularly in London, so that qualified practitioners could take a course under a skilled teacher. Practically all the schools questioned, including those in the dominions, had included in their full staff one or more of their visiting anaesthetists. But this was not the case, Dr. Ross thought, in any Scottish school. In five of the London schools one or more resident anaesthetists were appointed. This had a

marked effect in improving results, and also furnished the best possible training for one who wished to take up the subject as his life work. Only by providing a twenty-four-hour service could the mortality rate in hospitals be kept within reasonable limits. In private the supply of skilled anaesthetists had certainly increased. Dr. McKesson had estimated that the number of persons doing anaesthetic work exclusively had increased within the last few years from four or five hundred to two thousand. As the result of all these efforts, Dr. Ross could not doubt that vast improvement had taken place. If, however, one turned to the statistics of the Registrar-General for England and Wales, and also for Scotland, the impression given was of progress in the wrong direction. In comparing the death rate from or under anaesthetics per hundred thousand population for the three pre-war years with the rate for all the post-war years Dr. Ross had been able to see, it appeared that in England and Wales there had been a rise since the war, but only from 0.8 to 0.9. In Scotland there had been a very substantial post-war rise.

| Year. | England and Wales.                     |  | Scotland.                              |  |

These figures could not be considered satisfactory. But the effect of adopting the measures already indicated had, in one hospital in Scotland, reduced the death rate by half between 1922 and 1924. Dr. Ross commended this point of view to the responsible authorities of the large hospitals.

Dr. E. I. McKesson (Toledo, Ohio) said that not enough time in lectures and clinical practice was given in most colleges for the proper instruction in anaesthesia. Particularly practical work under supervision was important; but, as pointed out, the student also needed to know the sciences underlying the subject and to be acquainted with what had been done by others. Toledo was outside a medical teaching centre, so that Dr. McKesson gave post-graduate instruction only, and the type of student was entirely different from that encountered in medical colleges. His students wanted to learn anaesthesia, having been in the practice of dentistry or medicine long enough to know the value of anaesthesia. They were a hand-picked group with intense interest. Dr. McKesson's plan consisted of practical instruction in the use of nitrous oxide-oxygen, etc., under supervision, and informal lectures and discussions of theory, of blood pressure and other reactions, and of technique for various cases. The supervised practice was by far the more important. The student was kept alert by intentional disorganization of his technique by turning off the gas or oxygen, or by changing the mixture. It was obvious that the most cordial co-operation of the surgeon and anaesthetist was necessary for such instruction in anaesthesia. Dr. McKesson believed that the best time to train anaesthetists was after the student had learned, by experience in practice, that anaesthesia was of great importance and desirable as a specialty. At the same time the routine instruction of medical students was necessary.

Dr. MARY E. BORSFORD (San Francisco) expressed admiration for the valuable work done in the specialty of anaesthesiology by the British. As to the comparative mortality rate referred to by Dr. Ross, she said that statistics were notoriously unreliable; the determination

of the cause of death accruing in the first twenty-four hours post-operatively was often difficult and occasionally impossible. There was also the question of perhaps greater accuracy in reporting fatalities. With the unfortunately lower standards in certain districts in the United States, where technicians were used as anaesthetists, she was confident that the mortality rate would exceed the British if chloroform were used as frequently.

Dr. TORRANCE THOMSON referred to the large number of students that had to be dealt with in a short time, and to the fact that the interests of the patient must always be the first consideration. He deprecated giving theoretical apart from practical instruction, and said it was his custom to deliver six lectures at the beginning of each term to the students with whom he was to work in the operating theatre.

Dr. FAIRLIE felt that Dr. Ross did well to stress the importance of the teaching of anaesthesia. He was interested in the comparative way in which the subject had been approached, and to hear of the methods adopted for instruction in the various medical schools.

Dr. MILLS (Dundee) said that certain advantages were enjoyed in a young and comparatively small school. The anaesthetist was recognized as a member of the staff, and the lecturer in anaesthetics had the status of any other lecturer in the university. The number of students being relatively small, each student secured thorough instruction in the administration of anaesthetics before he sat for his final examination.

Dr. WESLEY BOURNE (McGill University, Montreal) then gave a lantern lecture on the effects of ether impurities.

Before the annual meeting of the society, Dr. H. P. FAIRLIE gave a demonstration at the Glasgow Royal Infirmary of the intratracheal administration of ether and of nasal administration of nitrous oxide and oxygen gases. This was followed by a lantern lecture by Dr. J. ROSS MACKENZIE on carbon dioxide in gas and oxygen anaesthesia. He showed that the partial pressure of nitrous oxide at atmospheric pressure was insufficient to produce anaesthesia for major surgery, without reducing the percentage of oxygen below that in the atmosphere. The assistance to good anaesthesia derived from local and regional analgesia, re-breathing, and carbon dioxide were mentioned. The effects of carbon dioxide deficiency upon the patient were tissue asphyxia, nitrous oxide toxæmia, apnoea, and depression of the vital medullary centres. Re-breathing, when properly regulated, he considered a very important factor in gas and oxygen anaesthesia, since it conserved the patient's body heat, retained the carbon dioxide in the expired air, and at least delayed the onset of signs of surgical shock. Infants and children were difficult to anaesthetize with gas and oxygen because relatively to adults they had a smaller respiratory exchange, a larger vital capacity, and a smaller alveolar area from which gas and oxygen might pass to the blood. A face-piece with an expiratory valve, attached directly to the gas bag, and a small percentage of carbon dioxide greatly facilitated the induction in infants. The advantages of a small percentage of carbon dioxide were, Dr. Mackenzie believed, both operative and post-operative. The operative advantages were that it hastened induction, counteracted the respiratory depression of morphine, maintained the acid-base balance of the blood, promoted ready separation of oxygen from oxyhaemoglobin to the tissues, improved the general condition of the patient, indirectly gave tone to the heart muscle and intrathoracic vessels by stimulation of the respiration, and hastened anaesthetic recovery and convalescence. The post-operative advantages were that it protected the patient against abdominal distension, respiratory complications, thrombosis and embolism, as well as post-operative collapse. Ether was frequently required in gas and oxygen anaesthesia, and, when used, he was of opinion that it should be washed out of the blood and tissues either before or after the patient left the theatre. Auto-de-etherization and de-etherization by inhalation of carbon dioxide were reviewed. The dangers of carbon dioxide administration were urgent, but in his experience could usually be anticipated. They were epileptiform convulsions, asphyxia, rupture of alveoli from excessive intrapulmonary pressure and hypercapnia.

## Rebels.

### SIR JAMES MACKENZIE.

"MACKENZIE was a great doctor, the greatest, I believe, of our generation. He was a great man of science, a great observer, a great thinker, a great controversialist. But over and above all these things he was a great man, a great friend, true in heart, noble in spirit, dauntless in courage." This statement, made in the opening pages of the book, will be endorsed by many who know about Mackenzie and his work and by all who knew him well. It also stamps the author as a hero-worshipper, and such a one may sometimes depict his hero not actually as he was, but as he appeared to the worshipper. For a really interesting biography—and this one will certainly grasp the reader—the author should always be an enthusiast with a gift of picturesque writing.

An attempt has been made to render this book, *The Beloved Physician: Sir James Mackenzie*,<sup>1</sup> suitable for the lay and the medical reader, and not always quite successfully. The technical parts describing Mackenzie's medical work will probably prove beyond the grasp of the ordinary lay mind. The medical reader will probably be irritated by the elementary instruction of the layman in medical matters, but he will be rewarded by a singularly lucid account of the medical problems which confronted Mackenzie, and his method of solving them. As a new generation has grown up which accepts Mackenzie's teaching as authoritative, without knowing how it was evolved, we can strongly recommend this masterly exposition of his life work as extremely valuable to young practitioners.

*The Beloved Physician*, the name which came to be applied to him in Burnley, had in many respects a placid life, but the author deals with it in somewhat dramatic style. All readers of Mackenzie's writings are familiar with the case of the young mother dying in childbed as the result of heart disease. He made it the text of many a sermon, and it showed well the clinical value of one case in directing the physician's attention to special investigation. Here it serves to give an opening to the author's power of description and his tendency to a journalistic style of writing. He makes great play of the "giants" which crossed Mackenzie's path and threatened to wreck his progress. At times they took the form of the editors of medical journals, though the author of this book pays handsome tributes to two of them. At others, they appeared as "Harley Street," and again as all who failed to appreciate the greatness of the man. As a matter of fact, Mackenzie's experience was the same as that of all great medical pioneers—their discoveries are not accepted at first. What the profession has to be thankful for is the fact that Mackenzie was a first-rate fighting man, and poured his views down the throats of the doctors—in season and out of season. Mackenzie was a golfer, and when requiring a niblick in a bunker he used to call for his claymore. At times this was the sort of weapon he used in controversy, and there is little doubt that he thus accelerated the general acceptance of his views by many years.

There runs through the book a curious contradiction in that Mackenzie is at one time pictured as ignored and misunderstood in London, and at another as loaded with all the honours his professional brethren and country could give him. The author even apologizes for the fact "that some passages of the book are inspired by bitterness or unkindness or sarcasm," and explains this by saying they are directed first and most of all against himself because he did not grasp Mackenzie's meaning and aims until late in the day. This method of relieving an author's feelings does no good to the hero's memory, nor does it tend to historical accuracy. It appeared to many that Mackenzie's views were often difficult to grasp, and it may be left an open question whether the fault lay with the exponent or the hearer. There is no doubt that one reason was his actively progressive mind—he was constantly at new ideas based on a substratum of facts not sufficiently understood by his audience. Mackenzie was distinctly an

elusive personality, and the author of his biography might have developed this side of his character rather than indulge in sarcasms levelled at the medical profession.

The personal details about Mackenzie's life are extremely interesting. With the knowledge of what was to follow, it is delightful to read that on going to school at the age of 5 years, "when he returned home again, after the first day's work, he announced that his education was finished. He had had enough of it." Apprenticeship in a chemist's shop followed school life, and it is very terrible to read in these days of his working hours—"twelve hours on each week-day, fifteen hours on Saturday, and four hours on Sunday." On the Saturday nights, when Mackenzie could not get home before midnight, "his mother was accustomed to pull up a blind of the farmhouse, and set a lighted lamp in the window, so that he might see this sign of welcome a mile or so away on his lonely journey. Mackenzie never forgot that lamp." Readers will enjoy all the personal details of the doctor's life in Burnley, at first in residence with the senior partner, and later in his own house at Bank Parade. No event was more important than his marriage, which, judging by the happy result, must have been arranged in heaven. All friends of Mackenzie will also feel indebted to his wife for the family details which she has given in this book and which she alone could give.

Full justice is not, we think, done to the last great adventure, the settling in St. Andrews. The work at the institute there, and the stimulating effect of Mackenzie's presence and guidance, are fully described; he himself, however, was dreaming great dreams and pondering over the future of medicine. Not everyone understood this, and some of his readers were puzzled. While in the past his work had naturally been limited to a great extent to the study of the heart, he now sought to find out the laws which governed the production of symptoms in all forms of chronic disease. He believed that such laws existed and ought to be discovered. The path probably lay through the recognition of the disturbance of physiological laws. To physiological laws and to the description of physiological processes he turned, but found them to be unsatisfactory and in many respects untrue, so far as the current teaching went. And so death came to the old warrior, the old general practitioner, and found him struggling to find out new great general laws which would aid the progress of medicine.

### BONE DISEASES: INFLAMMATORY AND TOXIC.

THE appearance of a new book on the somewhat complicated subject of bone disease is always a matter of interest, and particularly so when the author is a practical surgeon who has also made an intimate study of the subject from the pathological side. The advantages of this combination are well seen in the recently published work of Mr. LAWFORD KNAGGS on *The Inflammatory and Toxic Diseases of Bone*.<sup>2</sup> It is probable that this country is unsurpassed in the wealth of material existing in its museums exemplifying the various diseases of bone, and in illustrating his subject the author has wisely made use of this material, not only from the extensive collection in his own university of Leeds, but also from the abundant material in the Royal College of Surgeons and the London and provincial medical schools. The result is a volume possessing the satisfactory features of being eminently practical, in that the clinical aspect is kept in the foreground, while the pathology of the subject is adequately treated and its practical bearing duly emphasized. The author's plan of accompanying his descriptions of the several diseases by means of clinical histories of actual cases and of referring, as far as possible, to actual specimens accessible to his readers in museums, is excellent; these features, with the addition of good illustrations, form the best possible basis for a satisfactory exposition. The illustrations number, on the average, one to every other page, without undue crowding, and of their quality the beautiful figures of leontiasis ossea

<sup>1</sup> *The Beloved Physician: Sir James Mackenzie*. A Biography by R. Macnair Wilson. London: John Murray. 1926. (Demy 8vo, pp. 2 + 316; 1 portrait. 12s. net.)

<sup>2</sup> *The Inflammatory and Toxic Diseases of Bone*. By R. Lawford Knaggs, M.C. Cantab., F.R.C.S. With numerous photomicrographs by G. H. Rodman, M.D., Hon. F.R.P.S. Bristol: J. Wright and Sons, Ltd.; London: Simpkin, Marshall, Hamilton, Kent and Co., Ltd. 1926. (Med. 8vo, pp. xii + 416; 197 figures. 20s. net.)

may be mentioned as good examples. The author evidently attaches much importance to good illustrations.

In the matter of classification, by including in a single group both inflammatory and toxic diseases, the difficulty of satisfactorily placing certain diseases, such as osteitis fibrosa, has been avoided; practical considerations have led Mr. Knaggs to include the neuropathic arthropathies; he has appropriately placed them between syphilitic disease and osteo-arthritis. An interesting chapter has been appended on osteogenesis imperfecta. The ground covered by the volume includes the non-specific inflammations, with which are grouped Perthes's and Köhler's diseases; the specific inflammations; Charcot's joints; yaws; arthritis deformans; pulmonary osteo-arthritis and allied conditions; rickets; infantile scurvy; osteitis fibrosa; osteomalacia; osteitis deformans and leontiasis ossea.

In an interesting discussion on the relation between osteitis deformans, osteitis fibrosa, and osteomalacia, the author expresses the opinion that the three diseases have a similar and possibly identical origin. The lesion in osteitis fibrosa and osteitis deformans is practically the same; in both there is a marked degree of fibrous marrow, associated with a production and an absorption of osseous tissue. In osteitis deformans ossification outruns absorption, whereas the reverse is the case in osteitis fibrosa. It is suggested that this depends on differences in the vital resistance of the patient to toxic influence. This view is to some extent supported by clinical experience, for osteitis fibrosa is a disease of young people, while osteitis deformans affects middle and advanced life; further, the victims of osteitis deformans usually show marked evidence of arterial disease. The argument, therefore, leads to the inference that a susceptible individual with a sufficient resisting power may stave off osteitis fibrosa in youth, but succumb to osteitis deformans in old age, with its failing vitality. In accordance with this view, osteitis fibrosa and deformans are regarded as different expressions of the same disease. The relation of osteomalacia to the other two diseases is similarly explained; the resistance in this disease, owing to the severe depression of the patient's vitality, is so slight that the fibrosis of the marrow is unaccompanied by bone formation, the sole effect being degeneration and absorption of the osseous tissue. In connection with Charcot's disease the author advances an interesting theory in explanation of the excessive bone formation which occurs in the hypertrophic form. He has observed that the excess is usually found in cases where there has been rapid attrition of the ends of the bones, and he suggests that large numbers of osteoblasts are thereby set free into the joint cavity and give rise to the masses of bone around.

As indicated on the title-page, the book is intended to be a textbook for senior students; to these it will be of great service, but doubtless it will be welcomed by a wider circle. It was undertaken, so the author states, in order to create an interest in the leisure that follows retirement from active surgical duties; we feel sure that he has, in the completed work, furnished interest for many others besides himself.

#### CLINICAL EXAMINATION OF THE NERVOUS SYSTEM.

We recently had the pleasure of reviewing the French edition of Professor MONRAD-KROHN's admirable little book published under the above title. The third English edition<sup>2</sup> is now before us, and the standard of previous editions is more than maintained. The book is the best short account of the clinical examination of the nervous system, brought into line with the results of recent research, with which we have met. Dr. GRAINGER STEWART points out in an introductory note that the book is not a translation from the Norwegian, but has been written in English by Professor Monrad-Krohn, who is a Member of our own College of Physicians. He is to be congratulated on his clear style and diction, and on the remarkable

completeness of the information which he has made available within such a small compass.

The routine of examination recommended is on the generally recognized lines, but the notable feature of the book is the account it includes of clinical methods dependent upon recent knowledge which, though fully accepted, has not yet passed into the currency of the textbooks. Such subjects are the reflexes of spinal automatism, associated movements, examination of cerebellar function, cistern puncture, etc. There are admirable short accounts of all of these, though we may differ from occasional statements, such as that "in extrapyramidal motor lesions of the paralysis agitans type there is a marked diminution or loss of all associated movements." Kinnier Wilson has shown that this is a misinterpretation of the facts.

The book will be found of value by clinical teachers as well as by house-physicians and others working in the wards, while many in general practice will appreciate a brief account of modern methods. There are a number of aptly chosen photographic illustrations and some diagrams in the text.

#### RIDER HAGGARD.

SIR RIDER HAGGARD, who died last year at the age of 69, left behind him an autobiography coming down to 1912. It has been edited by Mr. C. J. LONGMAN, and published with the title *The Days of My Life*.<sup>4</sup> The book, which is in two volumes, is discursive, but its author was a practised writer, and knew well how to keep his reader's interest alive. Haggard was one of a class that grows scarcer, partly because families grow smaller. It consisted of younger sons of squires and lairds reinforced from the parsonage and the manse. Their fathers were able to give them as good an education as the grammar schools and minor public schools could afford, and at an early age many of them sought fortune overseas; some of them failed, some of them became active in public life overseas, some made money and came home, where not a few of them took their share in local and national affairs. For the foreigner's view of the value of this class to the nation and the Empire reference may be made to the opinion Mr. W. H. PAGE expressed in one of his letters written from England during the war.

Haggard got his overseas experience early, and made money at home. He began life at the age of 19 as secretary to Sir Henry Bulwer, who had been appointed Lieutenant-Governor of Natal; he had some varied and exciting experiences, especially when on the staff of Sir T. Shepstone, which served him well when he took to writing romances. After about five years as an official he resigned, married, set up with a friend as a farmer, and purchased a stock of ostriches. Like a good many others on the spot, Haggard was distressed by Mr. Gladstone's bargain with the Boers after Majuba, and, believing that it would lead to a long period of unrest and eventually to a big war, as it did, he sold his farm and returned to England in 1881. He was called to the Bar, but to maintain his family took to writing stories; their growing success, culminating in *She*, induced him to give up the law. All along he had had one foot in the country, for he had gone to live in Norfolk, the county in which he was born, as early as 1882; there he came in time to live the life of a typical country gentleman of the active-minded sort, farming his own land, becoming chairman of the local bench, standing for Parliament and coming within a little of success, and eventually taking a rather prominent part in the investigation of national and imperial problems affecting the land and the workers on it. He emulated Arthur Young by an inquiry into the conditions of life in rural England, and made an arduous journey on the other side of the Atlantic to report on labour colonies.

His interest in public life led him to write (1898) *Dr. Thorne*, a novel of vaccination. It was the story of a young medical man who fell into the toils of the anti-vaccinators. He was invited to stand for Parliament as a

<sup>2</sup> *The Clinical Examination of the Nervous System*. By Professor G. H. MONRAD-KROHN, M.D. Oslo, M.R.C.P. Lond., M.R.C.S. Eng. With a Foreword by T. Grainger Stewart, M.D., F.R.C.P. Third edition. London: H. K. Lewis and Co., Ltd. 1926. (Cr. 8vo, pp. xvi + 201; 82 figures, including 12 plates, 7s. 6d. net.)

<sup>4</sup> *The Days of My Life*. By Sir H. Rider Haggard. Edited by C. J. Longman. In two volumes. London and New York: Longmans, Green and Co., Ltd. 1926. (Med. 8vo, Vol. I, pp. xxv + 394; 9 plates. Vol. II, pp. ix + 226; 7 plates. 28s. net the two volumes.)

Radical and antivaccinator, and after a brief struggle, not exactly between ambition and conscience, but rather between ambition and intellect, he agreed. In our review of the book at the time we said that it "will be eagerly read for the sake of its vivid pictures of life and its powerful study of a complex human character by those who would never trouble their heads about vaccination further than to be revaccinated when an epidemic is threatening." Our expectation that the book would be read has been amply fulfilled, and it is still to be obtained from Messrs. Longman. As, however, Haggard had at that time parliamentary ambitions it called for some courage to write it.

In the peroration to this autobiography he described himself as "a lover of the kindly run of men . . . a lover of the land, and of all creatures that dwell therein, but most of all, perhaps, a lover of his country, which, with heart and soul and strength, he has tried to serve." This is a fair statement of the motives that inspired him throughout his life.

### "BRAIN."

THE current issue of *Brain*,<sup>5</sup> vol. xlix, Part 3, opens with an article by Dr. W. J. Adie, in which he describes twenty cases, including five which he has observed personally, of a syndrome to which it is proposed to apply the term "idiopathic narcolepsy." It is characterized by attacks of two kinds: in the one the attack consists of sudden and irresistible sleep of short duration; in the other, as the result of some sudden emotion, the muscles relax suddenly and the patient sinks to the ground, but without loss of consciousness. In a few cases sleep attacks only occurred. Reasons are given by which the syndrome may clearly be distinguished from epilepsy, hysteria, and other conditions. In only two instances has the condition in typical form been found to follow encephalitis lethargica. In an interesting discussion, Dr. Adie considers the mechanism of sleep, especially Pavlov's work on conditioned reflexes in which he found that inhibition of conditioned reflexes led to a tendency to sleep, and that, in fact, internal inhibition and sleep were probably identical processes. In several of the cases Dr. Adie describes, symptoms and signs were present suggesting pituitary disease, and he believes that idiopathic narcolepsy is a functional disorder of an endocrine-nervous system comprising the pituitary body and adjacent structures in the "tween-brain." This article will well repay study in detail.

Drs. James Charles Fox and Gordon Holmes contribute an important article on "Optic nystagmus and its value in cerebral lesions." This is a type of nystagmus which occurs when an individual gazes out of the window of a fast-moving train, but a similar nystagmus is brought about when a drum with vertical lines upon it is rotated in front of a normal individual. The authors employ a drum upon which are coloured pictures instead of vertical lines. It is found that when the drum is rotated in a clockwise direction, and viewed from above, nystagmus develops in an individual watching the drum; it consists of a quick phase to the right and a slow recession—that is, a nystagmus is produced opposite in direction to the rotation of the drum. Converse conditions hold when the drum is rotated anti-clockwise, and an analogous vertical nystagmus can be obtained when the drum is rotated on a horizontal axis. In an investigation of a large number of cases of cerebral lesion, including 41 cases of cerebral tumour, Drs. Fox and Holmes have found that this optic nystagmus may be abolished in one direction—namely, to the opposite side, in unilateral cerebral lesions. Their observations support the hypothesis that reflex centres for optic nystagmus lie in the occipital lobe and in the second frontal convolution, and that these are connected by a reflex path. Since optic nystagmus is present even if visual acuity is very slight, and however restricted the visual fields, it is clear that it forms a new localizing sign of considerable value.

<sup>5</sup> Published in London by Macmillan and Co., and in New York by the Macmillan Company. Yearly subscription in this country 24s., to be sent to Messrs. Macmillan, St Martin's Street, London, W.C.2. Price per part 6s. net.

### NOTES ON BOOKS.

WE must confess that the title of Mr. T. N. Roy's book, *The Organon Modernised*,<sup>6</sup> led us astray. We expected to find a modern version of Bacon's *Novum Organum*, for we had forgotten that Hahnemann also wrote a monumental organon. Mr. Roy presents this work in an abridged form, and commends it not only to students of homoeopathy, but also to psychoanalysts and students of heredity and biology. In Part II the author advances a new theory "to scientifically explain" the action of homoeopathic medicines. Briefly, his theory is based on the researches of Kucharenko on crystals. According to these, it is the nature of crystallons which explains the need for high dilution and the therapeutic action of inert substances such as gold. Through the theory of crystallons also Mr. Roy is able to explain the action of hormones, to prove the success of homoeopathy in chronic disease, to show the cause of the failure of the allopath, the enantiopath, and the isopath, and to demonstrate the wild-goose chase that is pursued by the vitamin-hunter. Mr. Roy has acquired an immense amount of information; his book is full of delightful sentences, such as "The gland-therapists are just in the chickenhood of homoeopathy"; and he has a remedy for the unfriendliness which he says exists between allopathists and advocates of homoeopathy. The proper sphere, he says, of allopathy is surgery and certain acute cases where homoeopathy is uncertain of success. The proper sphere of homoeopathy is the chronic disease and those acute diseases which do not run too rapid a course. Mr. Roy is, perhaps, a person of profound wisdom: he is D.H.A., M.A.G.A., and also field expert to the Government of Bengal.

The volume by Dr. ARTHUR WEBER, published in Berlin, on electro-cardiography and other graphic methods in circulatory diagnosis,<sup>7</sup> does not contain a comprehensive account of all the methods available. The "other methods" of the title are restricted to those for the photographic registration of the apex beat, arterial and venous pulses, heart sounds and respiration; of the use and interpretation of these, as well as of electro-cardiography, short and simple accounts are given. The book is therefore not so much for the general practitioner as for the medical officer in charge of a hospital heart clinic where a dark room is available. The electrical instruments described are the Edelman modification of Einthoven's galvanometer and the electro-cardiograph of Siemens and Halske. Detailed consideration of experimental and theoretic aspects are omitted, but there are numerous references to the original papers. The illustrations on the whole are only fair, due partly to the fact that they appear to be reproductions of paper strips, and partly because too many curves are recorded on one strip.

The second part of the second volume of the *Annals of the Pickett-Thomson Research Laboratory*<sup>8</sup> contains a series of papers with illustrative plates dealing particularly with the corynebacteria and the etiology of tuberculosis. The volume is intended to assist working bacteriologists by giving detailed information about the puzzling group of "diphtheroids," the nomenclature of which is in great confusion. The numerous plates and the tabulation of the distinctive characteristics of each species are very helpful in this respect, and a full list of references to original papers is included.

### PREPARATIONS AND APPLIANCES.

#### A Gastric Clamp.

MR. DONALD MACLEOD, F.R.C.S. (Leigh, Lancashire), has devised a clamp, which he finds most useful for the operation of gastro-enterostomy and also for pylorotomy, in which there is always danger of retraction of the stomach walls from the blades of the

usual type of clamp. The instrument is an extremely light screw joint flexible clamp; the edges of the blades are raised at intervals to prevent slipping, and, in order to provide additional security in this respect, a small stud is placed on the inner surface of one blade, at its tip, fitting into a small recess on the opposite blade. The clamp has been made for him by Messrs. Archibald Young and Son, surgical instrument makers, Edinburgh.

SATURDAY, OCTOBER 30TH, 1926.

## VOLUNTARY HOSPITALS AND THE BODY POLITIC.

VOLUNTARY hospitals are institutions of such mark that it is inevitable that the attention of publicists and officers of the State should be drawn to them. Indeed, they are clamant of attention, without which they cannot accomplish the work for which they exist. They make a twofold claim: a claim on the individual and a claim on the community of individuals—the State. And the claim is recognized by both. On the reverse side also a twofold claim is made: the individual (whether patient or benefactor) looks to the hospital for certain effects, and the body politic (through its representatives) looks to these hospitals for maximum effects upon the public health.

In the days when the bulk of our hospitals were founded, less than two hundred years ago, the idea of their founders was clearly individual—the cure of the sick man, woman, and child. It was the response made by an individual to an individual, of the well and able to the unwell and unable. There appears to have been little, if any, thought of a community effect. Indeed, at that time the State was callous to the last degree towards the lives of its citizens. Its laws were brutal, its tolerance of evil shocking. "Gin Lane" was justified in the interests of agriculture! The awakened conscience of individuals broke through social neglect, and to-day the appeal of the awakened social conscience is so vehement that it is thought by some to threaten to shoulder out individual effort. But a visit to only one hospital (or even the surgery of one private doctor) will calm such apprehensions. There, it is one to one, doctor to patient, nurse to sufferer—a complete absorption in a single aim. And this is as it must ever be. The attitude is not a limitation of view. It is the continuation of the spirit of pious founders which aimed at an individual recovery truly, but it embraces the larger view of a better public health, for only by health in the individual can there be health in the body politic. Both in religion and in medicine the eighteenth century reformers aimed at individual salvation, but as "he which converteth a sinner . . . shall cover a multitude of sins," and he who cures a sufferer will relieve a host of ailments, so each secured an effect wider than the immediate, and each advanced the public weal.

Nevertheless, there is a change of attitude to-day. The advancement of the idea of public health, and the high position it has attained—and rightly so—in the public mind, has brought to the forefront the problem of co-ordination of effort. The field of endeavour is too precious to allow of waste, of overlapping, or of competition. Although there is in effect now existing a high degree of co-ordination of effort between State hospital and voluntary hospital, as between private practitioners and public health officers, secured by mutual accommodation and good-will, yet there is evidence of a desire for something more than this as between the hospitals—for some formal alliance or scheme of co-operation. This desire was pointed out by a speech made by Mr. Neville Chamberlain, the Minister of Health, at the Coventry and Warwickshire Hospital on October 19th. He said that public health could not be treated in water-tight compartments, and

that in any survey of the general health question the part played by huge public institutions like the voluntary hospitals could not be left out of account. He thought the time had nearly come when the voluntary hospitals might be fitted into some scheme covering a wider field than any that had hitherto been formulated. Then followed the suggestion that a time would come when those responsible for the conduct of voluntary hospitals might be represented on some central health authority upon which would rest the responsibility of the general hospital policy of the area. In return for a certain subordination of their complete and absolute freedom to do what they liked the voluntary hospitals might be willing to receive some further assistance than that they got at present; under a system of that kind a central authority upon which the voluntary hospitals would be represented might lay down in the broadest possible outline the principles upon which questions such as extension should proceed, while leaving to each individual unity the widest possible freedom in the administration and conduct of its work.

Mr. Chamberlain hoped that the idea would not frighten his audience. It will not frighten doctors, at any rate. The British Medical Association has already faced the problem, and published its considered opinion in the *Hospital Policy of the Association*. In 1923 the Representative Body adopted a series of resolutions on the co-ordination of voluntary, Poor Law, and municipal hospitals. It held that there was danger in the overcrowding of voluntary hospitals, and the isolation and understaffing of Poor Law hospitals. It urged the extension of the principle of the Local Voluntary Hospital Committees (set up under action taken on the report of Lord Cave's Committee) so as to make them co-ordinating bodies for all hospitals, to ascertain the hospital accommodation existing and required, both as regards general and special hospitals, centres in rural districts, and convalescent homes. And that "the Committees should not interfere with the domestic autonomy of the several hospitals of whatever type within their areas, but act only in an advisory capacity; each type of hospital should be encouraged to work upon those lines of local initiative which have proved so vital in hospital work." It also conceived the enlargement of the Voluntary Hospitals Commission into a Standing Consultative Hospitals Committee as a "buffer state" between Ministry and local hospital committees. There is in these citations sufficient likeness to the ideas expressed by Mr. Chamberlain to make us hope that when he comes to formulate legislative proposals which must affect the Poor Law hospitals, co-ordination of effort may be secured without injuriously cramping individual effort.

It is satisfactory to find that though certain passages in his speech at Coventry have been taken to mean that the policy of the Ministry of Health is to secure the subordination of hospitals and of the medical profession to the Ministry—or, in other words, to secure what is primarily called a State Medical Service—Mr. Chamberlain has repudiated this interpretation. He has stated, first, that the general practice has been, and will continue to be, to have recourse in the greatest possible extent to the private practitioner "on terms which are the regular subject of discussion with the British Medical Association and with the responsible local authorities"; and, secondly, that his policy in regard to the hospital question is based on the same principle. He is, he says, and always has been, a firm supporter of the voluntary hospital system.

## ETHYL ALCOHOL SUBSTITUTES.

ORGANIC chemistry in the last few years has been developed on new lines; indeed, a new branch of the subject seems to have arisen which has already borne fruit in the syntheses of important organic products from inorganic sources. The new method, which may well revolutionize the manufacture of many important commercial organic compounds essential in the arts, depends on the utilization of high temperatures and pressures not previously available.

If carbon monoxide prepared from water gas is reduced at a high temperature and pressure in the presence of a catalyst, methyl alcohol is produced. Previously this compound was obtained from America, where it is prepared by distilling wood, and the impure product is termed "wood alcohol." Wood alcohol is employed in large amounts in this country; over a million gallons, for example, are used annually in the preparation of varnishes. The Germans are now said to be producing it in large quantities by the method indicated, at a cheaper rate than the Americans can produce it from wood. But this is not the whole story: by altering the physical conditions under which the reaction occurs it has been found possible to produce the higher homologues of methyl alcohol—particularly common ethyl alcohol and iso-propyl alcohol. It seems likely, unless unforeseen difficulties occur in the manufacture, that in the future this method of production will supersede all others. Although ethyl alcohol also can be prepared by this method, neither in France nor in Germany is it being pushed; it may be that the authorities think it more important to their countries to encourage the cultivation of potatoes, from which alcohol is prepared by fermentation. Those who have been following the trend of this branch of chemistry can hardly fail to appreciate that synthesis of carbohydrates for food purposes is already on the horizon.

Ethyl alcohol is by far the most generally useful of the alcohols in pharmacy and medicine. It is an important agent in the extraction of active principles from drugs, and is largely used in the manufacture of perfumes. The excise duty on ethyl alcohol is, however, so high that it is natural that search should be made for substitutes which would serve the purposes of ethyl alcohol, but be cheaper. Several proprietary preparations are in fact now on the market as substitutes for ethyl alcohol. By far the most important constituent of these is iso-propyl alcohol, which can be bought, roughly, at about half the price of ethyl alcohol. This alcohol has been used in lotions and as a vehicle for external medication, for washes, gargles, dentifrices, and particularly in perfumery. An Interdepartmental Committee is now sitting to consider the question of ethyl alcohol substitutes, particularly in reference to its bearing on revenue, trade, and public health, and the uses to which these substitutes may be put.

Pure iso-propyl alcohol is a colourless liquid with an alcoholic odour; it is miscible with water; its boiling-point—82.4° C.—is higher than that of ethyl alcohol—78.5° C. Commercial varieties may contain traces of aldehydes and ketones, which impart a disagreeable taste and smell. Iso-propyl alcohol is absorbed more slowly than ethyl alcohol, and its effects are somewhat different. It will be remembered that ethyl alcohol has a selective action on the more recently developed portion of the central nervous system, the so-called higher centres, and the good-humoured liveliness of the moderate consumer of alcoholic beverages is due to a relatively greater

sedative effect on the controlling centres than on others. This effect is much less pronounced with iso-propyl alcohol; it partakes rather of the nature of a hypnotic than a "stimulant," and gives no satisfaction to the spirit drinker. Even in America, where almost every available substitute for alcohol has been used, it finds no favour. Its toxicity, weight for weight, is certainly greater than that of ethyl alcohol, but probably not twice as great. So far as our information goes, no ill effects can result from the absorption of a few cubic centimetres, such as might occur when it is used as the vehicle in a mouth-wash, douche, or dentifrice.

## THE PANEL CONFERENCE.

THE chief subjects considered by the Annual Conference of Representatives of Local Medical and Panel Committees last week—a full report of which appears in the SUPPLEMENT (p. 189)—were the procedure in connexion with complaints against insurance medical practitioners, and the increase in claims for sickness benefit in its relation to medical certification.

The procedure in connexion with complaints is the administrative matter which is at present most in the minds of insurance practitioners; and, indeed, the Representative Body of the British Medical Association has this year declared it to be of fundamental importance to the whole profession. The report of the Insurance Acts Committee to the Conference contains a letter sent in July last by the Committee to the Minister of Health (see SUPPLEMENT, August 14th, p. 117). This letter placed clearly and strongly before the Minister the points to which it was desired to direct his immediate attention. Whereas up to the time of the receipt of this letter the attitude of the Ministry seems to have been entirely negative and unhelpful, two letters quite recently received from the Ministry indicate a more complete realization of the position and of the need for some drastic modifications of procedure. Both of these letters were placed before the Conference, and one of them was published in the SUPPLEMENT of October 16th (p. 173). The proposals made in these communications relate to (1) the control of those Medical Service Subcommittees which have a tendency to ignore the time limit within which complaints must be lodged; (2) irregularities on the part of approved societies or their agents with regard to medical certificates; (3) an appeal from the decision of the Minister in certain classes of case. On the first two matters the Minister appears to go as far as can reasonably be expected at the moment. He is prepared to "require that the decision in the first place as to whether a complaint should be heard by the subcommittee should be given by him in any case in which the chairman proposes to investigate a complaint not made within six weeks after the event giving rise to it and the practitioner objects to an investigation taking place on the ground that unreasonable delay has occurred in submitting the complaint"; and to consider an amendment of the law which might give him power to impose penalties in cases in which there is irregularity on the part of approved societies or their agents with regard to medical certificates.

It was the third of these points, relating to disciplinary procedure, which led to an important debate at the Conference. For some years past there has been before the Annual Panel Conference a resolution asking for an appeal to the courts from all decisions of the Minister on disciplinary matters. In this wide

form the proposal has never yet been endorsed either by the Insurance Acts Committee or the Conference. There are obviously some very grave objections to it, and the letter of the Committee to the Minister dated July 5th, with the Minister's reply dated October 9th, make it clear that these are recognized on both sides. It is nevertheless true that there is a manifest and strong feeling in the medical profession that there must be some protection against unreasonable action on the part of any Minister beyond that which is at present afforded by a possible appeal to the courts on the ground of irregular procedure, and that it is intolerable that the Minister should determine any issue which is of a purely professional character. The suggestion of the Committee and the Conference is that there should be certain defined classes of case in which an appeal should lie. The suggestion of the Minister is that in the most important class of case indicated he should be guided by an advisory committee composed of "independent practitioners of recognized standing whose impartiality could not be questioned." He states that he would be prepared to accept nominations by the Insurance Acts Committee of a "small panel of practitioners regarded as suitable to act in this capacity, from among whom would be selected those whose advice would be sought in particular cases." The Minister recognizes that the definition of the class of case to be referred to the advisory committee, and various points of detail of procedure, must be the subject of careful consideration with the profession; but assuming that these matters are satisfactorily determined, and assuming, of course, that the Minister would in fact accept the advice given on questions involving medical issues, the proposal seems to afford a hopeful basis on which a satisfactory solution of a difficult matter may be founded. The Conference decided that the Insurance Acts Committee should negotiate with the Ministry with a view to such a solution.

The other main subject before the Conference was brought to its notice in an entirely unofficial, frank, and confidential manner by Sir Walter Kinnear, controller of the Ministry's Insurance Department. Such occasional and informal visits from officers of the Ministry with a view to placing the Conference in full possession of facts necessary for the formation of a sound judgement are very welcome and useful, and Sir Walter Kinnear's was no exception. The seriousness of the position which may arise indirectly from the great increase of claims to sickness benefit during the last few months was fully appreciated by the Conference. The explanation of this increase is probably not so simple as is sometimes assumed, and the question is not without its difficulties; but in this connexion a doubt may certainly arise as to whether some practitioners when giving certificates may not be unduly influenced by the economic circumstances of the patient rather than guided solely by the consideration of capacity for work as required by the Insurance Act; and as to whether the extreme ease with which an insured person may change his doctor may not carry with it some unfortunate disadvantages. The resolution passed by the Conference asks the Insurance Acts Committee to consider what practical steps can be taken to meet the situation, and the representatives pledged themselves "to use their influence locally in endeavouring to secure strict adherence to the principles governing certification for the purposes of the National Health Insurance Acts." If the Insurance Acts Committee can successfully carry out its mandate on these important matters, this year's Conference will prove among the most fruitful of the series.

#### SICK HEADACHES.

THE full report with which this issue opens, of the discussion on migraine at the Annual Meeting this year, is, we venture to say, well worthy of study by general practitioners, especially those who have among their clients any considerable proportion of the professional and business classes. To such a person the recurrence of severe headaches is a serious handicap; to ascertain their cause becomes a matter of first-rate importance. The investigation of migraine is always embarrassed by the difficulty of definition. We must give up hope of being helped by etymology, for the word is a French contraction of hemi-crania, and the pain is not by any means always one-sided. Dr. Edwin Bramwell, in opening the discussion, spoke of the classical attack of migraine as comprising "an aura which is characterized by visual and it may be other phenomena indicative both of local and general disturbance of cerebral function, headache which is typically frontal and predominantly unilateral, nausea and vomiting." But he had at once to qualify this by stating that the headache might occur alone, that, in children particularly, vomiting might be the only symptom, and that the visual disturbances, the paraesthesia, and the palsies, any or all of which may attend the headache and vomiting, may occur without either but in circumstances which point to their migrainous nature. Dr. E. I. Spriggs, who made an interesting practical contribution to the discussion, took as a working definition "a periodic headache usually with some kind of aura, going on to vomiting, beginning in childhood or youth, and often hereditary." As to the etiology of true migraine, it seems to be agreed that there must be a predisposition, usually hereditary, which enables a rather long and diverse list of determining causes to act, but as to the actual mechanism of the attack there is no such unanimity. Dr. Bramwell sees in it a vascular derangement, a localized spasm of the cerebral arteries during which the aura and other prodromal symptoms occur, followed by a relaxation, when the headache due to engorgement of the meningeal vessels is the chief symptom. Dr. Gordon Holmes would not accept this view, and sought an explanation in a local swelling of the brain due to a temporary disturbance of the osmotic relations of its substance to the fluid in which it is bathed; this swelling could be supposed to produce the aural palsies, and by pressing on the meningeal nerves to cause the headache. Dr. Timme of New York took the opportunity of expounding his theory, which is that the symptoms are caused by growth in size of the pituitary body raising the intracranial pressure locally and generally, but he said also that migraine was a term which covered a number of conditions; this brings us to what we conceive to be the value of Dr. Spriggs's statistics. He took one hundred cases in which the major symptom for which the patient had been induced to apply for treatment was headache. Of these in twelve only was the diagnosis of migraine made, whereas in thirty-seven the attacks were considered to be due to some gastric condition, which in twenty-three instances was constipation. Reference was made to cases in which the symptomatic treatment of that condition, leading to regular natural action, cured or greatly diminished the migraine. The upshot of this is that any case in which there is a temptation to make the diagnosis of idiopathic migraine should be very thoroughly overhauled in search of some lesion or disorder, perhaps gastro-intestinal, the cure of which will check or possibly arrest the migraine. This surely is a useful hint.

#### PROGRESS IN ANAESTHESIA.

It is natural that the opening address in a discussion devoted to the future of a specialty should combine a paean for past triumphs with the promise of future victories. So it is with the inspiring paper published in our present

issue (p. 775) with which Dr. Samuel Johnston of Toronto opened the Section of Anaesthetics, over which he presided, at the Nottingham meeting of the British Medical Association. For future advance in anaesthesia Dr. Johnston looks to the efforts of the International Anaesthesia Research Society, a body which demands for its Record the evaluation of surgical and anaesthetic risk before operation, pre-operative therapy, five-minute blood pressure guides during the operative period, and post-operative therapy and care in order to reduce morbidity to a minimum. We are not sure that the British surgeon would accept the ideal of Dr. McMechan of Ohio that the anaesthetist "should dominate the preparation of the patient, the patient himself during induction and maintenance of the anaesthetic, and the after-treatment during the post-operative period." Dr. Johnston desires that every medical practitioner should be qualified to give safely, pleasantly, and efficiently such anaesthesia as may be required in painless childbirth and in minor surgery. Some of the specially trained and experienced anaesthetists would be required for hospital work in smaller towns. After years of practice such anaesthetists might look forward to staff positions of similar importance to those of the anaesthetists who have been elected to the teaching staffs of hospitals in large centres. To provide all these categories teaching in anaesthesia is necessary; and the teaching anaesthetist must be the liaison officer between the research laboratory of the medical school and the surgical department of the hospital. Dr. Johnston speaks with pride of the system of anaesthesia that has been developed in the Toronto General Hospital, where there is now a department consisting of a chief and eight assistants, all of whom are specialists in the art. The chief is a member of the medical advisory board of the hospital. He is also lecturer in anaesthesia in the Faculty of Medicine of the University of Toronto. It is interesting to note that earlier in the month of July Dr. Stuart Ross gave his presidential address on "The provision of an anaesthetic service" (summarized at page 789) to the Scottish Society of Anaesthetists, the report of whose meeting has just reached us. Dr. Ross had taken the trouble to elicit answers from anaesthetists, attached to medical schools in this country and the dominions, to various questions on the teaching and organization of anaesthetics. He appears to have found that, in the larger schools in England matters were fairly satisfactory, but that in Scotland the position was by no means happy, and that there had been a substantial post-war rise in the death rate from or under anaesthetics. Furthermore, the figures produced by Dr. Ross seem to show that the proportion of anaesthetic deaths in Scotland which occur under chloroform or mixtures containing chloroform is extremely high. Dr. Ross thinks that the significance of the figures for chloroform is open to doubt. They are certainly surprising in a country which has always prided itself on the method adopted for the administration of this anaesthetic. The moral of the investigations by Dr. Ross, no less than of the opening address of Dr. Johnston, seems to be that the advance of surgery needs a corresponding advance in methods, teaching, and research in anaesthetics; and that improvement in the status of the anaesthetist will conduce to this advance. So that perhaps we may agree with Dr. Johnston that "it is not too much to hope for the establishment in the near future of a chair of anaesthesia in every university where medicine is taught."

#### NEW HOSPITAL CENTRE FOR BIRMINGHAM.

In order to meet the growing need of Birmingham for hospital accommodation, the Hospital Council in April last invited the governing bodies of the General and Queen's Hospitals to consider a scheme for a new hospital centre, to be erected on a site adjacent to the University at

Edgbaston. The invitation was accepted and a joint committee appointed. The committee recommended that the new centre should be under the joint control of the General and Queen's Hospitals, which should be amalgamated for all purposes; that the unified board of management should have at its disposal a minimum of 1,200 beds; and that the new hospital centre should start with a minimum of 750 beds. The committee points out that the existing hospitals serve not only the population of Birmingham, approximately a million people, they have in addition to meet demands from a radius of more than thirty miles from the city, embracing a population of about three millions. The magnitude of the problem is apparent, and in considering it the committee had in view three main elements: (1) the provision of additional beds; (2) provision for out-patients and casualties; (3) the maintenance of the medical school. With regard to additional beds, the present deficiency is from 600 to 800. It is calculated that the total requirements in five years' time will be not fewer than 2,400. This will mean that 600 extra beds will be required in voluntary hospitals by 1931, the remainder being provided in the hospitals of the guardians of the poor. The departments for out-patients and casualties will have to expand proportionately. The medical school is at present split up, the hospitals being at some distance from the scientific departments. The removal of the medical faculty to the actual site of the hospital centre would bring about the necessary unification. These considerations can be satisfied by the erection of the new hospital centre on the proposed site. The scheme has been given a splendid send-off by the gift to the city of an area of 150 acres of land adjacent to the University by Messrs. Cadbury Bros., Ltd., together with a donation of £5,000 towards the initial expenses of laying out the site. It is stipulated that as much of this land as shall be agreed upon by the City Council and the Hospitals Council in consultation shall be secured for hospital purposes, and shall be leased to the hospital authorities at a nominal rent.

#### MODERN HOSPITAL ABUSE.

A NEW Division of the British Medical Association has been formed at Windsor. This is a matter for congratulation. It was an anomalous situation that there was no Division in the royal borough where is the chief residence of the Patron of our Association. We wish the new Division much success in its work. At the inaugural meeting under the presidency of Dr. F. J. Hathaway, the chairman of the Division, an address was given on the subject of "The modern hospital conception" by Mr. N. Bishop Harman. Incidentally, he dealt with a new form of hospital abuse. Abuse by individuals was, in his experience, diminishing owing to the efficiency of the modern almoner system; he held that in a full development of hospital facilities for all classes there would be no hospital abuse. But there was an increasing volume of abuse arising from the exploitation of the hospitals and their staffs for the treatment of industrial disease and accident. Yet no arrangements were made for meeting the costs to the hospitals, which were heavy, as for remuneration of the medical staffs. The companies gained materially, and their shareholders benefited, by the good treatment given to these patients in hospitals. So also with the numerous road accident cases. In the discussion that followed the paper it appeared that the King Edward VII Hospital, where the meeting was held, was a particularly heavy sufferer from this form of abuse. We have received also reports of a discussion on this same subject at the quarterly meeting of the governors of the Royal Devon and Exeter Hospital. Here the matter was raised by the lay members of the board. The *Hospital Policy of the British Medical Association* contains a paragraph on

the relation of insurance companies to hospitals, but things move so fast that it is hardly definite enough to meet present-day conditions. It reads: "Greatly extended support to voluntary hospitals should be sought from employers and insurance companies, seeing that they benefit largely, both directly and indirectly, by the services of the voluntary hospitals." Mr. Bishop Harman cited a precedent in the practice of the State of New York, where the law lays the onus of payment for the medical treatment of compensation cases upon the employers and the insurance companies. That, he thought, afforded an indication of what might be done in this country.

#### LESSONS FROM TISSUE CULTURES.

THERE would seem to be no better method of studying the biology of cells than that of culture *in vitro*. The cell can be isolated and its inherent powers of growth and differentiation studied under conditions which can be varied at the will of the observer. Further, by the method of tissue culture the mutual relations of cells and the influence of one type of cell on another can be investigated. Since Harrison, some twenty years ago, watched the growth of the isolated spinal axis of the embryo frog in lymph the method has been used by numerous experimenters, in regard to both normal and pathological cells, and the technique has been brought to great perfection, chiefly through the work of Carrel and Burrows. Before, however, it can be usefully applied in pathological research it is necessary that the biology of the normal cell shall be fully worked out, and in this direction considerable progress has already been made. Some very interesting investigations on the normal cell have recently been recorded by Strangeways and Fell. They have shown<sup>1</sup> that if the undifferentiated limb-bud of the embryonic fowl is cultivated *in vitro* it undergoes a considerable amount of progressive development; well marked differentiation of tissues and distinct indications of the formation of limb-segments occur. Recently<sup>2</sup> still more remarkable results have been obtained with cultures of the embryonic eye of the fowl. The embryos were incubated for sixty-four to seventy-two hours; one eye was dissected out (the other being left for purposes of control) and grown in a centrifuge tube containing a mixture of embryo extract and plasma. When first explanted the eyes appear as minute colourless bodies which are difficult to distinguish with the naked eye. After twenty hours' growth the optic cup has enlarged and is seen as a small grey vesicle surrounded by a diffuse growth of mesenchyme. By the second day the explant has about doubled in size and the pigmentation has increased, so that the eye is dark grey in colour. The rate of growth is greatest between the second and fourth days of cultivation; after that it falls off rapidly, the maximum size being reached about the eighth day. Examined histologically the eye, in the earliest explants, consists merely of an optic cup composed of two layers of undifferentiated cells containing little or no pigment, and a simple lens vesicle, the wall of which is of uniform thickness without any local thickening indicative of the future lens. In this simple structure the authors were able to follow the development of pigment, the different zones of the pars optica of the retina (rods and cones, inner and outer nuclear layers, inner and outer plexiform layers, ganglion cells, and nerve-fibre layer), the pars ciliaris retinae, and the fibres of the lens. This remarkable differentiation of the structures of the eye took place in the normal manner, and, in the later stages, at almost the normal rate. The authors draw special attention to the disparity which is observed between the rate of growth and the rate of differentiation. After seventeen

days' growth the retina may exhibit a histological structure almost equivalent to that of the retina of a day-old chick, whilst the greatest length of the explant is only 1 to 2 mm. It therefore appears that inhibition of normal cellular multiplication is not necessarily correlated with inhibition of normal tissue differentiation. Another instance of the value of this form of research is that relating to the effects of irradiation upon mitotic cell division. Strangeways and Oakley observed<sup>3</sup> that when a tissue culture in which cell division is active is subjected to small doses of  $\alpha$  rays, a decrease or complete disappearance of mitosis occurs. A closer examination of this result has led to the following interesting conclusions.<sup>4</sup> The earliest recognizable effect of  $\alpha$ -radiation upon growing cells is the temporary inhibition of the onset of mitotic division in the majority of those fully formed vegetative cells which are about to divide, while cells actually undergoing mitosis are unaffected; but if a cell, immediately prior to the visible prophase, is subjected to a dose of  $\alpha$  rays above a certain strength, it will enter mitosis, but the process of division will be of an abnormal type and may result in complete disruption of the cell. Variation in the quality of the incident beam of  $\alpha$  rays appears to have little or no effect, and no evidence was forthcoming that the rays exercise any stimulating effect on cell division.

#### A SYNTHETIC REMEDY FOR MALARIA.

CHEMISTS have tried for many years to produce synthetically quinine and its allied compounds, and at the eighty-ninth conference of Naturforscher und Ärzte at Düsseldorf in September communications were read on a new synthetic remedy for malaria, "plasmochin." It is an alkaloid with certain genetic relations with quinine. Its action on canaries experimentally infected with bird malaria has been tested in the zoological laboratory by Dr. Roehl of Elberfeld, who devised a quantitative method for the purpose. Professor Sioli of Düsseldorf has used it also for the treatment of general paralytics artificially infected with benign tertian malaria. The effect on the temperature, number of parasites, and general well-being was satisfactory; the upper limit of dose was determined by the appearance of cyanosis. Finally, the drug was tried by Professor Mühlens and others at the Hamburg Tropical Diseases Institute, where 134 patients with malaria contracted in various countries were treated from August, 1925, to the date of his report; they were mostly chronic or relapsed cases previously treated with quinine. The results generally were satisfactory, and the effect of the drug is now being tested in recent cases of malaria by Professor Mühlens in the Balkans, by Dr. Roehl in Spain, and by Professor Memmi and Dr. Schulemann in Italy. Some of these cases were treated with plasmochin and quinine prescribed in combination. In the Balkans and Italy no relapses of tertian malaria have occurred within six weeks of treatment; in Italy recurrence of tropical malaria was occasionally observed, but this, it is noted, may occur after treatment with quinine even when large doses are used. A point is made of the ease with which children, and even babies, accept the treatment; the drug is often administered to them in a suspension. The haemoglobin content of the blood has been observed to increase, and rapid decrease of the enlargement of the spleen during treatment has been observed; this, it is held, tends to show that the blood cells are not injured. Several cases of blackwater fever have been treated without any untoward results; among them were two in which quinine was thought to have produced haemorrhages. The compound of plasmochin and quinine is being used for prophylaxis. Professor Mühlens and his

<sup>1</sup> Proc. Roy. Soc., B, vol. 23, 1925, p. 349.

<sup>2</sup> Ibid., vol. 109, p. 273.

<sup>3</sup> Ibid., vol. 25, 1923, p. 373.

<sup>4</sup> Strangeways and Hopwood: Ibid., vol. 100, 1923, p. 283.

colleagues, holding the view that without crescent carriers the wide spread of tropical malaria is impossible, and that plasmodium alone or in combination with quinine destroys the crescentic sexual forms of the parasite occurring in the severest tropical forms, consider that the new synthetic remedy may prove of value in the cure and prevention of the spread of malaria.

#### THE ART OF TRANSLATION.

IN the *English Review* for October there is an article by Dr. E. W. Adams on translation and the translator. In it Dr. Adams is concerned to defend the translator from the accusation *traduttore traditore*, while pointing out the difficulties with which he is beset. Dr. Adams does not agree with Emerson that all that is best in a book is translatable; but no man can have all languages at his disposal, so that the translator becomes an invaluable middleman whenever it is impossible to deal direct with the original producer. According to Dr. Adams, thought is naked when first conceived within the brain, and as it roams the chambers of the mind it gathers the apparel of language, the relation of which to thought is so intimate that to separate the two is not to strip but to slay. How Dr. Adams arrives at the conception of a naked thought we are not sure, since most people must think in terms of language, unless, like the deaf and dumb, or the artist and musician, they think in terms of vision. However this may be, the garment of language is appropriate to the nationality and mental make-up of the thinker and his reader, so that it would be impossible, says Dr. Adams, to translate the thoughts of Keats or Shelley into the holophrastic language of the people of Tierra del Fuego. These are circumstances in which translation must fail. Again, there is the difficulty of reproducing the rhythm, cadence, or harmony of the language in which the thought was enunciated. Nevertheless, the translator is an expert in his own line, and is comparable to a ferryman, bearing goods of price of which he is the owner as well as the goods of another. He unloads a mixed cargo at his home port. In a translation, says Dr. Adams, "an author cannot speak to you through yourself." You cannot conduct a conversation *à deux*, but must take with you to the interview a third person in whom you are not greatly interested. But it is better to interview an immortal through an interpreter than to have with him no speech at all. And there Dr. Adams leaves it. It seems to us that Dr. Adams has not discriminated between different classes of translator. Perhaps it is impossible to reproduce in a foreign tongue the thought of the poet and of the imaginative writer, though thoughts on canvas, in stone, or in melody can appeal with equal force to many nationalities. Not only are the nuances of language different and difficult to reproduce; the thoughts themselves have different appeals to different races. But these difficulties should not beset the translator of scientific works. In them the ideas can be reproduced provided the translator himself thinks in terms of his own language. The failure to do so makes him a bad translator.

#### LAY AID IN MEDICAL PROPAGANDA.

THE American Association for Medical Progress was constituted in New York City, and local branches are now being formed in various States. We have received the first annual report of the Santa Barbara County Branch. From this it appears that the association was formed for the purpose of disseminating authentic medical knowledge more widely amongst laymen, emphasizing particularly the results gained by medical research and its application to sanitation and other activities for human and animal welfare. An important part of the work of the association is similar to that of our Research Defence Society. Thus

one of its objects is "to resist the efforts of the ignorant or fanatical persons or societies constantly urging legislation dangerous to the health and well-being of the American people." In pursuit of this object the association made inquiry of all the medical colleges and research institutes in the United States as to how far the public was at liberty to visit medical laboratories. As a result a long list has been gathered of laboratories for animal experimentation at which any responsible person is admitted; or officials of humane societies are particularly welcome; or responsible persons are admitted, but those who have seen an operation on the human being are preferred; or accredited officers of humane societies are admitted; or only officials of humane societies who have seen an operation are allowed entrance. In all medical schools and research institutes certain rules are observed. Wandering dogs and cats brought to the laboratory are kept for a time for return to their owners if claimed. The animals are kept in the best sanitary condition. No operations are performed without the sanction of the director of the laboratory. If an operation is likely to cause greater discomfort than that attending anaesthetization, the animal is rendered incapable of perceiving pain. Exceptions to this rule can only be made with the approval of the director. In all cases possible the animal is killed painlessly at the end of the experiment. The American Distemper Committee has attempted to get in touch with the so-called humane societies by pointing out that their aims are similar—namely, the prevention of suffering in animals; but from the report of the American Association for Medical Progress the effort does not seem to have met with success. The association seems to be carrying on a large amount of publicity work, and hopes to protect the public against plausible quackery by constant reiteration of the elements of knowledge in non-technical language. As the branches of the association are controlled by means of a lay advisory board and a medical advisory board, there seems every reason to suppose that this lay effort in the dissemination of medical knowledge will keep within the bounds of what is authentic and legitimate.

#### THE BOARD OF CONTROL.

ON the recommendation of the Minister of Health, the King has been pleased to appoint Dr. Robert Cunyngham Brown, C.B.E., to be a Commissioner of the Board of Control, to fill the vacancy caused by the retirement of Dr. R. W. Branthwaite, C.B. Dr. Cunyngham Brown was originally in the Prison Medical Service; afterwards he became Deputy Commissioner of the Board of Control for Scotland. During the war he served with the Salonika Force, and then became D.C.M.S. Ministry of National Service and Deputy Director-General Medical Services, Ministry of Pensions. He retired some years ago, and we are glad to know that his great abilities are again to be at the service of the country.

#### PROFESSOR SCHMIEGELOW'S JUBILEE.

A LITTLE time ago we announced that the seventieth birthday of Dr. E. Schmiegelow, professor of oto-laryngology in the University of Copenhagen, would be celebrated on October 13th. On that day there was a large attendance to hear his last lecture at the Rigshospital before finishing his active career there both as head of the clinic and as professor. That he is not without honour in his own country was shown by the manifestations of esteem and regard from his townsmen and compatriots, who presented him with a striking portrait of himself painted by the well known Danish artist Henningsen. In addition, the brotherhood of laryngologists in other lands united to present him with a bas-relief portrait in bronze by the Swedish artist Gösta Carrell. This had been subscribed for

by friends and admirers from many countries, under the leadership of Gunnar Holmgren (Stockholm), who, in their name, presented it to the throat clinic of the Rigshospital. Amongst the representatives who supported him were numerous colleagues from Sweden and Norway, and amongst those from other countries were Burger (Amsterdam), Marschik (Vienna), Spiess (Frankfurt), von Eicken, Kuttner, and Flatau (Berlin), and StClair Thomson (London). The jubilee was further celebrated by a meeting of the Danish Oto-Laryngological Society presided over by Dr. Stranberg. The foreign delegates were made most welcome, with much private hospitality, especially from Messrs. Möller, Stranberg, and Schmiegelow.

#### PART-TIME EFFICIENCY.

Dr. L. J. PICTON, part-time medical officer of health for Winsford, Cheshire, produces reports which are both entertaining and instructive. His report for 1925 includes a review of the progress made during the last five years, together with "any further action of importance . . . contemplated by the local authority or considered desirable —by me." The staple industry of Winsford is the manufacture of salt from brine. As the mortality rate from cancer at Winsford is no higher than elsewhere, the theory that salt has anything to do with cancer has, says Dr. Picton, no support. In consequence of the pumping of brine for salt manufacture the neighbourhood is very liable to subsidence. By floating the houses on a raft of concrete not only is the danger from subsidence provided against, but the dampness of houses, which the British Medical Association's Subcommittee on Rheumatic Heart Disease in Children regarded as an important cause of carditis, is prevented. The Winsford birth rate is the second highest in the country, the infantile death rate is low, and the illegitimate deaths were nil. Dr. Picton is very keen on improvement in the health conditions of his district, and at the same time wisely prefers settlement by amicable negotiation to the use of the iron heel of officialdom. Thus we find him anxious that school clinics should be established, and that ante-natal work should be developed; but in both cases he has approached the local practitioners on measures for carrying out his ideals. With the consent of his council he submitted to the Ministry of Health a scheme for paying the practitioners for a report on the ante-natal conditions of expectant mothers. The Ministry declined to give its approval because the Maternity and Child Welfare Act of 1918 refuses to "authorize the establishment by any local authority of a general domiciliary service by medical practitioners." Dr. Picton denies that his scheme makes any such proposals; but as the wording of the section in the Act suggests the influence of British Medical Association policy, he has no doubt considered the advisability of discussing the situation with the Association. Further evidence of Dr. Picton's talent for amicable agreement is shown in the arrangement by which butchers send meat which is condemned by the inspector to the gasworks for destruction, and thus avoid the publicity of seizure. Winsford seems to be a most fortunate area. The housing conditions appear to be quite good, with a house for every four inhabitants and four-fifths of the houses low-rented; the water supply is fair, and is being improved; venereal disease is comparatively negligible (when a V.D. centre existed the patients almost all came by train from other towns); and the hospital question is being settled by means of a small local hospital staffed by the general practitioners. Dr. Picton notes an unusual outbreak of nephritis following symptoms of influenza. As is natural in a disciple of Dr. Vivian Poore, he deplors the absence of earth-closets; and he makes a vigorous attack on patent foods for infants.

#### BEIT MEMORIAL FELLOWSHIP IN TROPICAL MEDICINE.

THE trustees of the Beit Memorial Fellowships for Medical Research have under consideration the appointment of a Fellow to devote his whole time to research in tropical medicine. The appointment will be for five years at a salary of £1,000 per annum. If the research is conducted in the tropics the passage money out and home will be paid, and a grant may be made for necessary laboratory expenses. The deed of trust applying to all Beit Fellowships requires that every Fellow shall be a person of European descent by both parents, but otherwise of any nationality whatsoever who at the date of election shall have taken a degree in any faculty in any university in the British Empire approved by the trustees, or, if a woman, have passed the examination which would have entitled her if male to take any such degree. In exceptional cases the possession of a medical diploma registrable in the United Kingdom may be accepted in lieu of a degree. Applications, on forms to be obtained by letter only addressed to Sir James K. Fowler, M.D., Honorary Secretary, Beit Memorial Fellowships for Medical Research, 35, Clarges Street, London, W.1, must be received on or before February 1st, 1927. Candidates resident abroad should send written applications giving full particulars of their previous career, with references to any published scientific papers or other evidence of capacity for research. They should state the nature of the research they desire to undertake, and how it is proposed to attack the problems presented. No testimonials will be received, and canvassing the trustees or Advisory Board is forbidden. The candidate appointed will commence work at as early a date as possible.

#### CONFERENCE ON MENTAL WELFARE.

THE postponed conference on mental welfare, under the auspices of the Central Association for Mental Welfare, will be held in the Central Hall, Westminster, on Thursday and Friday, December 2nd and 3rd, beginning at 10 a.m. each day. On the first morning there will be a discussion on the proper care of defectives outside institutions, with Sir Leslie Scott, K.C., M.P., in the chair, and in the afternoon the Right Hon. H. P. Macmillan, K.C. (chairman, Royal Commission on Lunacy and Mental Disorders), will preside over a discussion on borderland cases, to be opened by Dr. Edwin Goodall and Dr. Kemlo Watson. On the second morning the training of teachers for special schools will be discussed, with Dr. H. B. Brackenbury in the chair and Lord Eustace Percy (President of the Board of Education) as the opening speaker; in the afternoon the subject of encephalitis lethargica and its after-effects will be introduced by Dr. A. F. Tredgold and Dr. F. C. Shrubbsall, under the chairmanship of Sir Archibald Bodkin (Director of Public Prosecutions). Tickets entitling holders to admission to all sessions, and to advance copies of papers, may be obtained from the offices of the association (24, Buckingham Palace Road, S.W.1) at a cost of 5s.

THE Hunterian Oration before the Royal College of Surgeons of England will be delivered by the President, Sir Berkeley Moynihan, Bt., on Monday, February 14th, 1927. Professor G. Elliot Smith's Thomas Vicary Lecture on "The significance of anatomy" will be delivered at the College on Thursday next, November 4th, at 5 o'clock, and Mr. Ernest W. Hey Groves's Bradshaw Lecture on "Reconstructive surgery of the hip-joint" on Thursday, November 11th. The annual meeting of Fellows and Members will be held on Thursday, November 18th, at 3 o'clock.

## THE BRITISH ORTHOPAEDIC ASSOCIATION.

## NINTH ANNUAL MEETING.

A MEETING of the British Orthopaedic Association was held in London on October 22nd and 23rd. The first morning meeting took place at the house of the Royal Society of Medicine.

After the short business session, Mr. H. A. T. FAIRBANK, the President, gave a presidential address on "Some general affections of the skeleton, including achondroplasia, osteogenesis imperfecta, and osteomalacia." He showed a large number of clinical photographs and radiograms illustrating the various points in the correlation of certain of these obscure bone conditions.

*Discussion on Injuries of the Carpus.*

The subject for discussion at the morning session was injuries of the carpus. Mr. MAX PAGE, who opened, commented on the fact that the knowledge of this complicated subject was of comparatively recent date. He quoted largely from Mouchet, Destot, and Kellogg Speed, and presented a simplified classification based on the findings of the French school. He dealt in some detail with the treatment and prognosis. Mr. S. T. IRWIN gave a careful analysis of the records of the Royal Victoria Hospital, Belfast, during a five-year period. He reported the incidence of each particular fracture, the period of disability, and the functional end-result. Mr. HARRY PLATT suggested a classification, similar to that of Mr. Page, and reported in detail the results of carpal injuries from his fracture clinic at Ancoats Hospital, Manchester, over a period of five years. Mr. THURSTAN HOLLAND, Mr. OLLERENSHAW, Mr. R. C. ELSLIE, and Mr. ST. J. D. BUXTON carried on the discussion. Sir ROBERT JONES gave the results of his great experience, and described the treatment he was accustomed to employ. He said that, with a fractured scaphoid, if the wrist moved freely under anaesthesia, he immobilized for three weeks in dorsiflexion, and the end-result was good. He had found that if the wrist did not move easily under the anaesthetic prognosis was less good. He did not consider that removal of the whole or part of the scaphoid, although sometimes necessary, resulted in a perfect hand.

*Clinical Meeting.*

A clinical meeting on Friday afternoon was held at St. Thomas's Hospital. Two operations were first performed, Mr. Bristow removing a torn cartilage from the knee-joint and Mr. Page performing arthrodesis of the hip. Then followed a clinical demonstration. Mr. BRISTOW showed a group of patients treated in the orthopaedic department of the hospital, illustrating points of interest in the surgery of the joints and bones. The first group illustrated the results obtained from modified arthroplasty of the hip, the reconstruction operation devised by Whitman—namely, excision of the head, remodelling of the neck, and lowering of the trochanter; three patients upon whose hips arthrodesis had been performed were shown for comparison. Four patients illustrated the end-results of the treatment for recurrent dislocation of the shoulder; one cured by a deltoid muscle sling, one by repair of the glenoid ligament after the Clairemont-Erich operation had failed; the other two patients were cured by a bone operation to raise the rim of the glenoid fossa, the glenoid ligament being found torn and so shrivelled as to be incapable of repair. Two patients illustrated reconstruction of the elbow-joint, and one in whom a fractured internal epicondyle had been removed from the interior of the joint. This patient, whose elbow was stiff for some long time, had recovered full movement. Two patients in whom arthrodesis of the ankle-joint had been done for old malunited Pott's fracture were shown walking well and without pain. Other patients illustrated the result of repair of muscle and tendon, bilateral rupture of the ligamentum patellae repaired by a free fasciae graft, and bilateral rupture of the quadriceps by transplantation of tensor fasciae femoris to the patella. Cases were shown of chronic sclerosing osteomyelitis (Garre), fibrocystic disease of the neck of

the femur dealt with by curetting and grafting, haemophilic knee, and adolescent coxa vara treated by open operation. A group of patients with affections of the knee-joint were demonstrated, illustrating the end-results after synovectomy, cheilectomy, and patello-femoral arthroplasty. Mr. PAGE showed two patients in whom he had removed five inches of bone from the femur to shorten the leg, and a patient who was cured of a clicking jaw by the removal of the interarticular cartilage.

The members were entertained to tea in the Shepherd Memorial Hall by the kind invitation of Miss Lloyd Still, the matron of St. Thomas's Hospital, after which a short visit was paid to the orthopaedic wards. Dr. J. B. MENNELL then gave a demonstration in the massage department of the methods he employed in manipulating the joints. He explained the various points of his technique.

*The Association's Dinner.*

In the evening a most successful dinner was held at the Café Royal. Mr. FAIRBANK, the president, was in the chair, and some eighty members and their guests were present. His Majesty KING MANOEL, the most distinguished honorary member of the association, made a graceful speech in response to the toast of his health. Sir ARTHUR STANLEY, treasurer of St. Thomas's Hospital, replied, in a witty speech, to the toast of the guests, which had been proposed by Sir ROBERT JONES. Sir JOHN BLAND-SUTTON proposed the health of the association, and the PRESIDENT replied. Professor MURK JANSEN of Leyden then proposed the health of the President. The guests of the association included Sir Arthur Stanley, Sir George Makins, Sir John Bland-Sutton, Sir James Berry, Sir Cuthbert Wallace, Sir Dawson Williams, Sir Squire Sprigge, and many other distinguished members of the profession.

*Short Communications.*

Saturday morning was devoted to short papers. Mr. E. P. BROCKMAN reported several cases of renal rickets, and showed a series of radiograms. He also showed a tibia from one of the patients and for comparison the tibia from a rachitic patient, and a normal tibia from a child of the same age. He had investigated the microscopic changes about the growth disc, and exhibited a series of coloured drawings illustrating the changes which he had found. The PRESIDENT warmly congratulated Mr. Brockman on his paper. Mr. PERKINS reported the end-results of the operation of excision of the head of the first metatarsal bone in fifty patients, from the orthopaedic department of St. Thomas's. He found that from the patient's point of view the operation gave a good result in 96 per cent. of cases. He called attention to the fact that pain about the fore-foot was not relieved by excision of the head, and that free mobility must be restored to the toes. He suggested that the bad results associated in the mind of some surgeons with this operation were due to coexisting pain about the fore-foot, and that treatment for the two conditions should be simultaneously undertaken. Mr. Perkins's paper was discussed by Professor MURK JANSEN, Messrs. OPENSHAW, MITCHELL of Belfast, ELSLIE, ARMOUR of Liverpool, BRISTOW, TRETHOWAN, ROCYN JONES, and others. Mr. LAMBRINUDI described an operation which he had devised for the cure of paralytic drop-foot, and showed two patients. Mr. BROCKMAN reported a case of femoral aneurysm arising in a boy suffering from Pott's disease of the spine. He exhibited the vessel which had been excised by Sir Cuthbert Wallace, and a microscopic section of the artery wall showing local tuberculous disease. Mr. BRALLSFORD (Birmingham) showed radiograms of the spine from patients illustrating spondylolisthesis—erosion of the bodies caused by aneurysm and the localization of a foreign body. Owing to shortness of time, papers by Mr. Max Page, Professor Murk Jansen, and Mr. Barnett, which were to have been presented, were taken as read.

*Visit to Open-air Hospital.*

On Saturday afternoon some forty members visited St. Nicholas's and St. Martin's Orthopaedic Hospital at Pyrford in Surrey. This open-air hospital of 160 beds, which

belongs to the Waifs and Strays Society, is staffed by the orthopaedic department of St. Thomas's Hospital and Dr. T. M. Hardy of Byfleet, who is the local medical officer. Members were shown round the hospital and visited the open-air wards, after which a clinical demonstration was given. A number of patients was exhibited, including a group of eight cases of pseudo-coxalgia with serial radiograms showing the various changes over a three-year period, and for comparison two patients with flattening of the head of the femur and cavitation of the neck. An informal discussion was kept up during the demonstration.

## A MEDICAL REVIEW OF SOVIET RUSSIA.\*

### IV.—CHANGE IN TYPE AND INCIDENCE OF DISEASE.

BY

W. HORSLEY GANTT, B.Sc., M.D.

(Formerly Chief of the Medical Division of the American Relief Administration, Leningrad Unit.)

#### PART II (continued).

#### GYNAECOLOGY AND OBSTETRICS.

##### *Amenorrhoea.*

AMENORRHOEA has been one of the chief gynaecological conditions arising from the famine. It was present in more than 50 per cent. of women and often persisted in many after a return to normal nutrition. There were no disagreeable symptoms, and many stated that they felt better when they were not menstruating. Chalator and others stated that the amenorrhoea acted as a compensatory factor; that those in whom it was present were in better health and had a higher percentage of haemoglobin than those menstruating; and that it occurred oftener in single than in married women.<sup>1</sup>

##### *Sterility.*

Sterility was not affected as far as could be ascertained. The sexual libido was markedly decreased and impotencia increased as a result of the hunger, lowered metabolism, and distraction of attention. There was a relaxation of the sphincters, particularly of the bladder. Dysmenorrhoea and metrorrhagia were not affected; menorrhagia was decreased.

##### *Abortion.*

The subject of abortion is so important that some detailed statistics will be given to illustrate the effect of the legalizing of abortions. Leaving aside the moral considerations, a seeming benefit is that more people would seek reputable physicians, and that there would be fewer infections. Would this be offset by the increase in undesirable pregnancies?

The former penalty for illegal abortion was exile of the mother and doctor to Siberia. Now the law requires that practically anyone applying can have it done, but that it must be done by a licensed physician in a public hospital. It is now illegal when performed by a midwife. It is done without fee if there is a medical certificate from the family physician showing some physical indication, or if there is a certificate from the *Narkomzdrav* committee (composed of a communal doctor and workmen) saying that there is a social or financial reason. If the patient does not bring one of these certificates a fee may be accepted by the surgeon. In Moscow there are special hospitals for doing abortions, but in Leningrad they may be done in any hospital.

There has been a rapid and continual increase in abortions in all the hospitals of Leningrad in which statistics were kept. The lack of moral and legal restraint does not account entirely for these increased figures because formerly

none of the abortions were registered except those done for medical indications.

TABLE III.—*Abortions: State Clinical and Obstetrical Hospital, Leningrad.*

| Authority.      | Year.             | Abortions. | Ratio of Abortions to Admissions. | Mortality. |
|-----------------|-------------------|------------|-----------------------------------|------------|
| Gugenberger ..  | 1883-93           | 21         | 2.6%                              | 0.0%       |
| Viridarsky ...  | 1883-93           | 150        | 2.6%                              | 0.8%       |
| Chaplin ...     | 1891-97           | 185        | 3.69%                             | 0.0%       |
| Jakovzev ...    | 1901-07           | 1,039      | 11.8%                             | 1.0%       |
| Bublichenko ... | 1907-13           | 3,674      | —                                 | 0.9%       |
| Gepner ...      | 1912-22           | 4,338      | 22.5%                             | —          |
|                 | 1922              | —          | 28.6%                             | —          |
|                 | 1923 (first half) | —          | 42.0%                             | 18.0%      |

In another of the large city hospitals (Erismann) 60 per cent. of all pregnant cases entering the hospital in the first five months of 1923 came to abortion. The *Statburo* gives 6,000 as the official number of abortions done in Leningrad in 1924; in 1925 there were 11,897, in 60 per cent. of which the women were between 20 and 30 years of age. (*Krasnaya Gazeta*, April 9th, 1926.)

In spite of the facilities afforded the public in these hospitals many women continue to go to midwives, I am told, because they fear the publicity of the hospital; in fact, most of the cases that enter the hospitals enter as incomplete abortions. The Gubzdrav figures show that abortions have increased sixfold during the past four or five years.

It is impossible to say what percentage of the cases are unmarried. In the first place, a woman may now register in her maiden name; and in the second place it appears that some are married just before entering the hospital, and, owing to the freedom of the present laws, divorced when they leave. However, during the past three years both marriage and divorce laws have been more stringent. But it is stated that pregnancy in young girls has greatly increased, and that special wards have had to be opened for this group of patients.\*

Dr. A. Genss, head of the department for mother and child welfare for Russia, in his book on abortions in Russia (Moscow, 1926), advances arguments for the legalizing of abortions. The system of permitting abortions in Russia succeeds, he says, better than that of forbidding them prevalent in other countries, and gives a comparison with Germany in 1924.

|                               | Germany.      | Russia.      |
|-------------------------------|---------------|--------------|
| Total number of abortions ... | 600,000       | 150,000      |
| Illnesses from abortion ...   | 78,000        | 3,000        |
| Deaths from abortion ...      | 7,000         | 1,000        |
| Sepsis from abortion ...      | 10 per cent.* | 4 per cent.† |
| Imprisonments (abortions) ... | 5,000         | None         |

\* Berlin. † Leningrad.

He gives as the number of abortions in New York in 1924, 130,000; in Paris, 50,000; in Berlin, 23,000; in Moscow, 8,000. The figures for Moscow in 1925 were 7,900, and for 1922 4,000, showing an increase for 1924, as do also the data for Leningrad. The proportion of illegitimate births in Leningrad for 1910-12 was 16 per cent.; in 1922, 14 per cent.; and in 1925, 17 per cent.

What has been the cause of this increase in immorality? Has it been due to a moral decay following the war and crisis through which Russia has passed, the breaking up of the home, the loosening of the hold of the Church, the utter dissolution through which everything has passed, or to the results of any specific teachings of the present régime?

Although there may have been cases where children have been wrongly instructed, I do not believe that most of the

\* Previous papers on medical and scientific work in Soviet Russia by Dr. W. Horsley Gantt were published in the *BRITISH MEDICAL JOURNAL* in 1924: II, Hospitals and Health Conditions in Soviet Russia, vol. 1, p. 1055; vol. 2, p. 533. The first part of section IV, on "Change in Type and Incidence of Disease," was published on August 14th last, p. 303. Part II of this section was commenced last week (p. 747) and is concluded in this issue.

\* More than 50 per cent. of the cases in one of the largest obstetrical hospitals entered as incomplete abortions in 1923, and 18 per cent. of these were infected; 0.5 per cent. entered with perforations, and in all the obstetrical hospitals of Leningrad 0.45 per cent. of the cases entered with perforations. These perforations occur in those who attempted to abort themselves. According to Professor Stroganoff there were ten times as many infections in the aborted cases as in the normal deliveries.

immorality has been due to this, nor do I believe, as I have been told, that it is a result of teaching youths in the primary and grammar schools the anatomy and physiology of reproduction. It has probably been a result of all the factors mentioned in the preceding paragraph. There have been also many more real indications, such as tuberculosis and malnutrition; nephritis and cardiac diseases have not changed in frequency. A prominent obstetrician attributes it to (1) poverty, tuberculosis, malaria, and anaemia; (2) spread of atheism; (3) absence of shame on account of the legalization. He says that the number of people who attempt abortion without a doctor has not diminished.

There has been a great increase in the number of tubal pregnancies all over Russia in the past few years. This was at first attributed to the increase in abortions and the use of iodine in the uterus. However, as the increase has also been noted in the villages and country where abortions and iodine are not in vogue, this reason has to be discarded. Fewer cases of puerperal fever have occurred since 1918-19.

The percentage of eclampsia in pregnancy has not changed in the past eight years from its normal of 0.2. Its mortality in some of the hospitals has been 14 to 16 per cent. (Marinsky), but in the State Obstetrical Hospital where Professor Stroganoff works it has been kept down to about 1 per cent. Stroganoff's technique consists in keeping the patient in a dark room, and the careful administration of chloral hydrate and morphine at regular intervals. It has been described in the *BRITISH MEDICAL JOURNAL* (July 12th, 1924, p. 53).

#### SURGICAL DISEASES.

The first important surgical conference in Russia after the war took place in Leningrad in September, 1922. Papers were read by the eminent surgeons Wreden, Federov, Grekoff, Spaskokutsky, and others. Some of these have been made use of in the following account.

*Class of Patients.*—The hard conditions of living affected mostly the city dwellers and the intellectual classes, and the great increase in surgical patients came from these groups. The lack of leisure and rest, the disorganization of nutrition, the physical and nervous exhaustion, were expressed surgically by a complete loss of resistance to infection. In these severe circumstances surgical diseases assumed quite a new character. Ordinarily trivial complaints became chronic and serious, and diseases formerly rare appeared suddenly as epidemics. For example, there was an epidemic of purulent infections, of hernias, abdominal ptoses, varicose, peptic ulcers, flat-foot, and necroses. On the other hand, the hospital register showed a decrease of cancer, erysipelas, and acute peritonitis, and a marked decrease of all kinds of appendicitis. The decrease in the first three diseases mentioned was probably only apparent, as during the bad conditions these patients died off too rapidly to reach the hospitals. The opinion is, however, that appendicitis underwent an absolute great decrease. The lack of abundant food may have played a part in this decrease.

*Cachexia.*—Beginning with 1917 there was an unexplainable and rapid emaciation, especially in the educated classes, which suggested a developing cancer or diabetes. Later appeared hunger oedema, which passed into a peculiar state of cachexia with atrophy of the tissues. Premature senility occurred in numbers of the young and the middle-aged, and it was accompanied by an enormous increase of the senile diseases—arterio-sclerosis, angina pectoris, apoplexy, gangrene of the extremities, etc. Grekoff says:

"The course of ordinary surgical diseases became so unusual that a surgeon of the old school, having been out of Russia, would be puzzled and have to learn anew, and to change radically the routine, methods of treatment, indications for operation, and his point of view of surgical pathology."

*Normal Patients.*—In spite of the conditions it was noticed that there was a small contingent of "normal" patients, who were well nourished and endured happily the most complicated operations, and whose wounds healed normally. These were usually peasants from villages which had not been affected by famine.

*Cause and Variety of Infections.*—The enormous increase of surgical infections can be attributed to two main factors: first, the abundance of dirt in the hospitals and the lack of means of cleanliness of the patient and of disinfection (soap, hot water, etc); secondly, the lowered resistance of the patient. In such an environment the most virulent infections resulted from the most trivial circumstances, such as slight scratches, hangnails, burns, stitches, chilblains, corns, lice, and insect bites. Cutaneous infections were also greatly increased (scabies, eczema, skin necroses, ulcers, furuncles, and carbuncles). There was an increased tendency to bedsores owing to the general emaciation. Dr. Grekoff states that he saw more paronychia in 1917-18 than in several decades of his preceding surgical practice. Dry gangrene of the finger-tips was not rare. Purulent tendo-vaginitis took a severe course and had a tendency to become an intramuscular phlegmon, and to be accompanied by extensive necrosis of subcutaneous tissue, skin, tendons, and muscles. These infections were said to be made worse by incisions, as an extensive necrosis spread rapidly from the wound edges to healthy skin areas; sacrifice of the entire limb was usually necessary to prevent death from sepsis.

*Other Rare Infections.*—Various affections of the vascular and lymphatic systems were seen in increasing numbers. The increase in arterio-sclerosis will be described under "Internal Diseases." There were more varicosities (resulting from the continual standing in line for food), thrombophlebitis, lymphangitis, lymphadenitis. The latter appeared almost as an epidemic; sometimes symmetrical glands were affected, and the surgeons became acquainted with glands the location of which was formerly unknown except to anatomists. Other rare infections which became common were: thyroiditis (purulent), idiopathic purulent parotitis, Mikulicz's disease (seven cases at the Obookoff Hospital in three years, against two for several preceding decades), purulent otitis, purulent perichondritis, inguinal buboes. Gangrene was frequent—not only on the tips of the extremities following typhus, but, without apparent cause except undernutrition, on the tip of the nose, the external ears, the laryngeal and costal cartilages, and in the lungs.

*Orthopaedic.*—Grekoff reports three cases in which he observed absorption of bone (caused by famine?). Corns and callous formations were greatly increased, as were also hydromas on the forearms. Pes planus was much more common than formerly. The fact that no great addition of surgical tuberculosis was noted may have been due to the rapid dying off of all tuberculous patients.

*Hernias and Prolapses.*—Hernias, prolapses, and abdominal ptoses were enormously increased, as a result of the hard physical labour, the loss of fat, and the weakening of muscles and aponeuroses. Every variety of hernia occurred in the young which was ordinarily found only in the aged, and the majority of all surgical patients, regardless of the chief ailment, had one or more hernias (Grekoff, Shamoff).<sup>\*</sup> Strangulation of hernias was frequently brought about by the great increase in coprostasis and meteorism, and operations could rarely be performed on account of the condition of the patient. Although the frequency of haemorrhoids was lessened, the number of cases of prolapsed haemorrhoids was relatively increased. Prolapse of the rectum and uterus was common.

#### Digestive Organs.

Maxillary osteomyelitis took a more severe turn than usual, and was not infrequently accompanied by fatal Ludwig's angina. Most of the digestive neuroses were greatly increased, such as spasmodic oesophageal stenosis simulating cancerous stenosis (the cancerous form being rare during these years), pylorospasms, cardialgia.

#### Gastric and Duodenal Ulcers.

Gastric and duodenal ulcers have been among the most striking and persistent of the surgical diseases. They were most prevalent in 1920-22, when a conservative estimate was that they were six times more frequent than before the war. At the present time (1926) they are said to be about twice as common as in the pre-war period (Bush and

<sup>\*</sup> A case with seven hernias was reported from the Obookoff Hospital.

Wreden). The greatest increase came about one or two years after the worst years, suggesting that this time was required for the development of the ulcer to the point of producing critical symptoms; a good many of the patients referred the beginning of their symptoms to 1918-19.

Two main factors have been mentioned to account for the increase: first, the rough, indigestible, and irritating character of the food (as described above); and secondly, the neuropathic experiences through which the population passed. This nervous influence, according to Grekoff and some others, exerted the greatest etiological force. In the first place, the ulcers occurred at about the same time that the neuroses occurred in greatest number; and secondly, ulcers often were noted from those villages where there was no acute famine, and in patients who were better nourished than the average. Patients with ulcer often showed marked neurasthenic symptoms, and gave in their history neurotic traumata, such as destruction of property, loss of kinsmen, etc. (Grekoff). Besides the general nervous influence, it has been suggested that there is a direct nervous or trophic disturbance due to the irritation of the sympathetic nerve in the case of duodenal ulcer, and of the vagus in the case of gastric ulcer. Spaskokutsky and Kraus of Saratov, however, have done experimental work during the last three years showing that mechanical injury produces ulcer (personal communication). Probably both the nervous and mechanical factors played a part.

#### Treatment.

Dietetic treatment was out of the question, and therefore the only relief for these patients was surgical. Gastro-enterostomy performed during this period often resulted in a jejunal ulcer or an enlargement of the original ulcer, and some form of pyloroplasty was found to be most efficacious.

**Experimental Gastro-enterostomy.**—Recently gastro-enterostomy experiments have been performed in Professor Pavlov's laboratory by Fursikov and Brestkin. The miniature stomach of Pavlov was made in three healthy dogs, and the juice found to be normal. Three months later gastro-enterostomy was performed, after which the acidity was markedly higher and remained high for three or four months. Then a second operation was done to break the gastro-enterostomy. In a short while the acidity in all three dogs returned to normal, and the unfavourable symptoms which had been noted when the gastro-enterostomy was present disappeared. (Personal communication of this unpublished work by the courtesy of Dr. Fursikov).\*

**Dilatation and Obstructions.**—The impaired nutrition and lack of neuro-muscular tone increased the frequency of acute dilatation of the stomach, and of intestinal obstructions (chiefly dynamic, though also mechanical). Impaction of faeces due to weak peristalsis was often a cause of obstruction. Ulcerative colitis and perityphlitis occurred. Infiltrations formerly easily dissolved became indolent.

#### Prognosis.

Owing to the reduction of the materials and of the staff, as well as the inability of the patients to endure operation, only the most urgent cases were attempted. If the patient did not die on the table he usually succumbed to post-operative pneumonia, heart failure, or sepsis. Surgical wounds required weeks and months to heal instead of days. It was the rule for them to become oedematous or infected, and the starting point of an extensive necrosis or gangrene, or to come apart on the slightest exertion. The cold of the operating room appeared not to be as dangerous as supposed. Grekoff states that he performed gastro-enterostomies when the temperature of the room was only 6° C., and that he never noticed shock or other complications although the intestines became rapidly cold.

#### Amputations.

The following table from the Obokoff Hospital shows the decrease in the total number of operations, a parallel

\* Dr. J. S. Hensley has suggested to me that inasmuch as these experiments were done on normal dogs they cannot be compared too closely with operations on the patient, who is not normal.

decrease in operations for a comparatively trivial ailment like hernia (although the number of hernias entering the hospital was greatly increased), and the increase in the percentage of amputations which had to be done to save the patient from death from a spreading infection.

TABLE IV.

|   | 1913. | 1918. | 1919. |
|---|-------|-------|-------|
| Total number of operations ... ..                                 | 2,085 | 987   | 491   |
| Percentage of surgical patients operated on for hernia.           | 7.2   | 3.7   | 6.2   |
| Amputations (percentage of total number of operations)            | 2.5   | 5.0   | 12.0  |
| Amputations (percentage of total number of all hospital patients) | 0.5   | 1.3   | 2.0   |

#### Mortality.

The increase in mortality of surgical diseases is shown in the following table.

TABLE V.

|                               | 1913 | 1914. | 1917. | 1918. | 1919. |
|-------------------------------|------|-------|-------|-------|-------|
| Mortality (per cent.) of:     |      |       |       |       |       |
| Surgical patients ... ..      | 3.8  | —     | 7.9   | 11.1  | 13.0  |
| Furunculosis ... ..           | —    | 4.0   | 7.0   | 29.8  | —     |
| Phlegmonous infections ... .. | —    | 4.6   | 6.6   | 21.6  | —     |
| Ulcers ... ..                 | —    | 0.6   | 6.5   | 35.5  | —     |
| Gangrene ... ..               | —    | 17.8  | 32.5  | 23.2  | —     |

\* The figures for surgical patients are those of Professor Maniloff; the others are from Professor Ponomareff. The decrease in the mortality of gangrene for 1918 resulted from the increase in the number of amputations.

Dr. N. S. Zvonitsky of the Narkomzdrav tells me that the deaths from cancer have increased from an average of about 90 per 100,000 population before the war to about 103 in 1919-24 in Leningrad, as compared with an increase in London from 85 in 1890-1910 to 94 in 1910-20; and with an increase in Berlin from 69 in 1881-85 to 153 in 1916-20.

#### Nerve Section for Trophic Ulcers and Cancer.

I obtained from Dr. R. R. Wreden, one of the leading Russian surgeons, the following account of the method of treating ulcer and cancer by the resection of nerves.

**Ulcers.**—Trophic ulcers have been greatly benefited by the cutting of the nerve which supplies the region of the ulcer, according to the method of Dr. Molotkov of Leningrad, the originator of this procedure. The nerve is cut across and the cut ends are immediately sutured. This is supposed to arrest the altered metabolism or inflammation in the nerve which is believed to be causing the ulcer. The pronounced hyperaemia of the region which follows may have something to do with the healing; the temperature is higher by 1½ to 2½° C. One of the cases in which remarkable recovery ensued was an ulcer over the tendo Achillis, 2 cm. in diameter, which had lasted fourteen months, and which had resulted from the entangling of the sural nerve in a callous formation following the fracture of both bones of the lower leg. The ulcer failed to granulate under any form of treatment. After section of the sural nerve the ulcer disappeared in fourteen days, and did not recur. Another was a case of tuberculosis of the bones of the arch of the foot with a painful fistula opening on the sole. The fistula, which had lasted for two years, healed completely in about two weeks after the section of the tibial nerve. Many similar cases have been reported.

**Cancer.**—Molotkov treats cancer also as a trophic ulcer, but the results have not been nearly so successful. Professors Wreden, Grekoff, and Bush have all tried the Molotkov method of nerve section and suturing in many cancers, but they inform me that only two of a large series have shown good results. In the following cases the carcinoma was demonstrated by microscopic section, and a complete disappearance ensued upon the nerve cutting.

One was in a physician who had a carcinoma on the index finger and an ulcer on the fourth finger of the same hand. A year ago Dr. Molotkov had cut the median nerve; fourteen days later the ulcer and the cancer disappeared, and have not returned. In the other successful case—a carcinoma of the upper lip—Dr. Grekoff cut the second branch of the trigeminal nerve close to the exit from the skull. The growth went away during the course of the following month, and has not reappeared; at the time of writing this the patient has been under observation at the Obokoff Hospital for sixteen months.

These two cases have given the method a wide publicity both in Russia and abroad, but the surgeons of Leningrad do not look upon it altogether with favour except for trophic ulcers. Professor Pavlov told me that he considered the method entirely in the experimental stage.

#### ANTHROPOLOGICAL CHANGES.

Anthropologists state that starvation is an important factor in causing degeneration. The prolonged famine and food shortage in Russia caused the following anthropological changes: a decrease in average height, and weight (up to 40 per cent.); a decrease in all dimensions of the head; a change in the facial and cranial indices; a decrease in the circumference of the chest; a decrease in Pignet's vital index. A. A. Ivanovsky, in an examination of 1,139 people, found that the skull is now longer in the anteroposterior diameter than formerly, the arms are longer, the face longer, the nose narrower, and the lips thinner. These are supposed to be a return toward the features of our primitive ancestors. Shefko reports that the number of stillbirths and monsters has increased. In an examination of a hundred skulls he found that the volume is smaller as a result of the famine, and he confirms the other findings of Ivanovsky. M. Spirtov, of the Academy of Science, Leningrad, tells me that the tissues which arise from the mesoderm in the embryo especially have shown faulty development. Ivanovsky claims that these anthropological changes will be present in the offspring as mutations and regressions, but Vishnevsky and Nikolov contend that these alterations are already showing a tendency to disappear.\*

#### CONCLUSIONS.

This review, besides recording the effects of fighting and famine on specific diseases in Russia, shows that the record of war is written as indelibly in health statistics as in battle fatalities in regard to both present and after effects. This has been seen in most of the combatant nations of Europe, but particularly in Poland and Russia, and even in such an ordinarily well ordered country as Germany.

While most of the modifications in disease can be blamed on the war and revolution (typhus, malaria, etc.), there are some which have resulted from governmental policies—such as the disappearance of alcoholism up to 1922, changes in the incidence of abortions, and decrease of infantile mortality and of typhoid fever. The public health department is making commendable and strenuous efforts, as described in another paper, but it may find that fallen houses, grass-grown streets, and musty factories are easier to repair than diseased and crippled bodies. One must remember that the present health is more a legacy of the past (war, revolution, famine, and ignorance) than a result of present policies. If allowance can be made for the backward state of Russia before the revolution, and for the terribly disastrous events of the wars, it will be interesting to see in the future what will be the health of a nation under this new form of government,† and to judge by the morbidity rates whether the living conditions of the masses will have bettered. From the progress already made in public health work it is likely that Russian health conditions will be better in the future.

#### REFERENCE.

\* Chalatov, S. S.: *Textbook of Pathology*, Leningrad, 1925.

\* I am indebted to Dr. M. Spirtov for bringing to my notice some of the above anthropological facts.

† One cannot, of course, take morbidity and mortality rates as an exact criterion of the worth of the abstract principles of the ruling party of a nation because these principles may be strictly followed by only a small percentage of the people.

## England and Wales.

#### HALIFAX INFIRMARY.

SIR BERKELEY MOYNIHAN, President of the Royal College of Surgeons of England, opened on October 20th a new operating theatre block at the Royal Halifax Infirmary. The erection and equipment of this extension has been made possible by a gift of £5,000 from Mr. Samuel Watkinson in memory of his parents and other relatives. The new theatre, with separate rooms for sterilizing, washing, and instruments, has been built as a complete unit independent of the existing theatre, with which, however, it is connected. The entrance lobby has an anaesthetizing room on one side, and on the other a recovery room fitted with a large cupboard for the provision of warm blankets to patients immediately after an operation. The theatre is lofty and well lit on its northern side by a studio window, with double glass to prevent condensation; a dark blind between two windows facilitates special eye and throat work. The walls of the theatre and its subsidiary rooms are covered with large vitrolite sheets, highly glazed, easily washed, and acid-proof. They are devoid of any fittings, such adjuncts as sinks, radiators, and towel rails being placed in the adjoining sink and washing room, following the practice in many new hospitals. Arrangements are made to control the heating and ventilation, air filters being provided for the removal of fog impurities, while the ventilation ensures a complete change of air every twelve to fifteen minutes without draught. The temperature is controlled by thermostats and pneumatic pressure operating steam valves. The sterilizing apparatus has a special ventilating plant to prevent free steam escaping into the general atmosphere, and the large sterilizer is hydraulically operated. The artificial lighting is provided by four ceiling lights and a central adjustable swing lamp, the light of which is controlled by numerous mirrors so as to abolish shadows. It is believed that these arrangements represent the last word in efficiency at the present time. The old theatre was constructed about thirty years ago. Sir Berkeley Moynihan, in his address, referred to the great traditions of the Royal Halifax Infirmary, and sketched the surprisingly swift advance of surgery during the last fifty years. He remarked that the longest journey the surgeon had ever taken was the little inch of space between the skin and the heart, which had occupied over thirty centuries. Cardiac and abdominal surgery was almost inconceivable fifty years ago. The credit for this advance must be attributed in large measure to the brilliant work of Lister, who was the greatest material benefactor the world had ever known. Surgical theatres and schools of medicine corresponded to the temples of ancient days, in which the physical and spiritual welfare were furthered simultaneously. The theatre was no longer a place of suffering, but rather a temple of science, and in it devotion, reverence, and compassion were exercised by men who felt themselves to be high priests in the service of humanity.

#### A YORKSHIRE BENEVOLENT SOCIETY.

The eighteenth annual meeting of the Medical Benevolent Society for the North and East Ridings of Yorkshire and the City of York was held at York on September 25th. The reports of the secretary and the treasurer were adopted. The financial statement showed that there was a satisfactory balance in hand, and the trustees were directed to make a further investment from the funds of the society. The objects of the society are to give assistance to its members or their families where it may be needed owing to illness or other disability or death. It is felt that the work of the society is not sufficiently known amongst the profession, and steps are being taken to bring its claims before all practitioners in its district; it is hoped there will be an increase of the support it receives. The honorary secretary is Dr. Henry J. Mackenzie (254, Bishopthorpe Road, York).

#### LONDON HOSPITAL OLD STUDENTS' DINNER.

The annual dinner of the London Hospital was held at the Trocadero Restaurant on October 21st. Dr. Russell Andrews was in the chair, and 225 old students of the hospital

were present, including Sir Neville Howse, V.C., the new Commissioner for Australia. In proposing the health of the hospital the chairman referred to the loss it had sustained by the death of Queen Alexandra, its president, whose constant and practical devotion to the hospital had been such a source of inspiration to all those engaged in its work. Queen Mary, in graciously accepting the vacant office, had given a further proof of the personal interest of the Royal Family in the hospital. The chairman spoke also with regret of the death of Mr. Mark Hovell, a member of the consulting staff, and for many years surgeon to the aural department. A reference to the long connexion of Lord Knutsford and Mr. E. W. Morris with the hospital, and a tribute to the incalculable value of their services as chairman and house governor, were greeted with loud applause. During the year three generous donors had each given a sum of £10,000 to the hospital for the service of its students—Mr. Alfred Williams for a research scholarship, Viscount Bearsted for a clinical lecture theatre, and Mr. Bernhard Baron for an extension of the pathological institute. In addition an anonymous donor had given the magnificent sum of £50,000 for the establishment of a "Freedom Research Fund." In the next few months a new cardiological department, new maternity wards, and a large hostel for the residents, would add still further to the opportunities which the London Hospital offered to its students. The resignations of Mr. James Sherren, Dr. E. W. Clapham, and Dr. Probyn Williams would fill all "Londoners" with regret, mingled with gratitude for the long years of service they had devoted to the hospital. With an even more personal regret they would hear of the resignation of Miss Brain, who would always live in their affection as Sister Victor. During the year there had been many additions to the visiting staff. Mr. A. C. Perry and Mr. H. W. B. Cairns had been elected assistant surgeons, Dr. Maitland Jones had been appointed director of the new children's department, Mr. William Morris and Mr. Geoffrey Carte had been elected surgeons to the aural, Dr. O'Donovan to the skin, and Mr. Victor Lack to the gynaecological departments. The hospital continued to attract students of a high order by its great reputation as a teaching school and its incomparable clinical material. It was a remarkable testimonial that among its present students were seventeen sons and three nephews of its old graduates. Old students might look forward with confidence to the future of their hospital, just as the hospital itself relied on the affection and patriotism of its children.

#### NEW HOSPITAL FOR WOMEN IN LIVERPOOL.

The foundation stone of the Liverpool and Samaritan Hospital was laid on October 14th by Mrs. E. W. Hope, the lady mayoress. The new building will contain 120 beds, and the cost of erection will be about £120,000, of which £61,000 has already been collected; in it the work now carried on by the Hospital for Women in Shaw Street and the Samaritan Hospital for Women in Upper Parliament Street will be combined and considerable extension will be possible. At the Shaw Street hospital during 1925 there were 1,331 admissions and 1,185 operations, while at the Samaritan Hospital the corresponding figures were 485 and 410. The number of beds at the Shaw Hospital is sixty, and at the Samaritan Hospital twenty, so that in the new building the present severe demand for beds should be decreased to some extent. The hospital will be equipped on the most modern lines and the voluntary tradition of the two institutions during the last forty years will be maintained. Accommodation will be provided for a limited number of paying patients.

#### VITAL STATISTICS FOR 1925.

We referred a fortnight ago (October 16th, p. 709) to Part I of the *Statistical Review of England and Wales for 1925* (Medical). Part II has now been issued and can be obtained (price 5s.) from H.M. Stationery Office or through any bookseller. The salient features are: The estimate of the population of England and Wales at June 30th, 1925, was 38,890,000, as against 38,746,000 in 1924, an increase of 144,000. The births registered in the year 1925 totalled 710,582, representing a rate of 18.3 per 1,000 population, which was 0.5 per 1,000 below the rate

for 1924, and with the exception of the war years 1917-18 was the lowest recorded. Excluding the years 1917-19, the number of births is the lowest number registered in any year since 1861. The proportion of male to 1,000 female births was 1,045. This proportion showed a great increase during the war years and reached a maximum of 1,060 in 1919, since when with one exception it has shown a continuous decline, but is still above the proportions recorded since 1860. The deaths numbered 472,841, and corresponded to a rate of 12.2 per 1,000, the same as for the previous year, but 0.6 more than that for 1923, which was the lowest on record. The marriages registered in England and Wales during the year 1925 numbered 295,689, corresponding to a rate of 15.2 persons married per 1,000 of the population; this is a decrease of 727 over 1924. The greatest number of marriages was again registered in the third quarter of the year, being 90,314, or 30.5 per cent. of the total, whereas the number for the first quarter of the year was 46,263, or 15.3 per cent. This preference for the third quarter has been a feature of the returns since the beginning of the present century; previously the highest rate was recorded in the fourth quarter. The number of decrees nisi made absolute during the year was 2,605 (2,563 dissolution and 42 annulment), as against 2,286 in 1924 and 2,667 in 1923.

## Scotland.

#### ANIMAL BREEDING AT EDINBURGH.

A GIFT of £10,000 by Lord Woolavington towards the endowment of a chair of animal breeding in Edinburgh has just been announced. It follows on an offer by the Rockefeller International Education Board of £30,000 for the extension of the Animal Breeding Research Department, on condition that a similar sum should be obtained in this country. A substantial grant in aid of the scheme is also expected from the Development Commission, and it is anticipated that the Department of Animal Breeding in Edinburgh University will be unique in the British Isles, and will greatly strengthen the school of agriculture as well as the scientific department of the Medical School. It is estimated that a capital sum of between £60,000 and £70,000 will be required. The history of the Edinburgh Animal Breeding Research Station is comparatively short. The suggestion that work on this line might be undertaken made by the Board of Agriculture in 1919 was selected as the centre probably on account of the work which had previously been done in this direction by Professor Cossar Ewart. The activities of the committee appointed to carry out the project were suspended until 1919 on account of the war. Dr. Crow was appointed director in 1920, and in February, 1921, accommodation was provided in an old building in High School Yards, the property of the University, where a small staff of workers was gradually collected.

In the sixth annual report of the Animal Breeding Research Department of the University recently issued, Dr. F. A. E. Crow stated that the transfer of the department to the King's Buildings in December, 1924, had provided room for considerable expansion. Research was being done in regard to the value of certain recognized breeding practices. Much that the breeder had already accomplished would receive the endorsement of science, and much that was at present held to be financially profitable would be ruthlessly condemned on biological grounds. Evidence was being accumulated to show that in certain instances the breeder was seeking to fix characters which were genetically unstable and to perpetuate what was biologically unworthy. The department had been engaged for a considerable period in the study of sheep-breeding problems, particularly in connexion with the fleece of the sheep, which occupied a special place among agricultural products because it was definitely a by-product which was sold directly by the farmer. The practical values characteristic of other animal products were not so well defined in the case of the fleece. Investigation had to be made into the relations that might exist between the nature of the fleece and mutton qualities, the suitability of sheep for

their environment, and special breed characters that might be termed points of valuation. The co-operation of the private breeder was essential, no less than that of the manufacturing expert. Breed characters having been defined, it had become possible to discover the variations that existed and to take advantage of this to lay down standards within a breed. While it was necessary to maintain a certain number of sheep at the department in order to conduct investigations, the great bulk of the work could be done on the flocks of institutions or of private breeders, who were willing to co-operate, without materially disturbing the normal management of the flocks.

Other problems already under investigation are the developmental intersexuality in the fowl, sex link inheritance in fowls, the influence of the ductless glands upon development, the pathology of calves in the Dexter breed of cattle, the factors involved in natural incubation of chicks, and an inquiry into the problem of sterility in cattle. Work is also in progress in regard to pigs, with a view to finding out which of the problems of the pig-breeder are amenable to genetical investigation. An example of the wide scope embraced in the investigations of this department is afforded by the arrangements made with the directors of the Stirling Bacon Factory and with the Prison Commissioners for Scotland in regard to pigs raised at Barlinnie Prison near Glasgow, with a view to investigating the live weight increase in proportion to food consumption, quality and maturity in different strains, and correlating these with the question of fertility. Various other pig-breeding societies are also collaborating with the department in this investigation. Somewhat similar investigations are being made with the help of other associations into problems connected with the breeding of horses, cattle, and goats. In addition to these investigations, a grant of £200 for five years from the Carnegie Trustees has enabled a biochemical laboratory to be equipped, so that many problems which cannot be solved by purely genetical methods may be more thoroughly investigated.

The staff of the department includes Dr. Crew as director, with Mr. A. D. Buchanan Smith, M.A., M.Sc., as assistant and liaison officer between the department and the agricultural community of Scotland. Over twelve research students, from the United Kingdom and from Australia, India, and Japan, have been working in the department. Courses of lectures have been given to students of agriculture in the University, as well as to students of veterinary science and students of the post-graduate medical school. Various public lectures have been given by the director and other members of the research staff, and Dr. Crew has given to the Dundee Branch a British Medical Association lecture on the mechanism of inheritance, which was published in the *BRITISH MEDICAL JOURNAL* of August 14th, p. 285.

#### MOTOR ACCIDENTS AND HOSPITALS.

Various voluntary hospitals have recently been concerned about the number of persons admitted to the wards owing to injuries in motor collisions. The Board of Managers of the Royal Infirmary of Edinburgh on October 4th discussed the question of making claims to meet the cost of treating such cases, and directed a return to be prepared. It was presented to the meeting on October 18th, and showed that during August 42 cases had been treated in the institution; up to September 1st these patients had received a total of 475 days' treatment. This had involved a cost for maintenance during the month of August of £184 1s. 3d., and 18 were then still under treatment. It was suggested that the attention of the insurance companies concerned should be drawn to the matter, and that they should be asked to make grants to hospitals for the treatment of such cases when disposing of their annual surplus. The principle, it was pointed out, had already been recognized by railway companies, and in one instance a substantial grant had been given in recognition of the services rendered by the infirmary following a collision. It was agreed that the matter should be raised again at the beginning of next year, and that a return of the number of cases due to motor accidents should be included in the annual report of the infirmary.

#### MATERNITY BENEFIT IN SCOTLAND.

One of the matters considered at the annual committee, held in Edinburgh on October 13th, of the Convention of Royal Burghs of Scotland, a body which has existed for several centuries, was the disposal of maternity benefit. A letter was read from the town clerk of Kilmarnock regarding the question of maternity benefit mandates in favour of local authorities. Sir Henry Keith, who was in the chair, said that treatment in maternity hospitals was not free, except in cases of necessity; the general practice was to charge for maintenance, and a practice had grown up with some local authorities of suggesting to the woman that she should assign her maternity benefit to the authority, in respect of the charges which otherwise would be made, as a form of security for payment of the expenses incurred. The Board of Health had originally favoured this plan, but recently some of the approved societies had objected to signing the mandate. This matter seemed to be one which could be settled by mutual co-operation and goodwill, and it might be approached either through the Association of Approved Societies or through the Association of Insurance Committees, before seeking new legislation on the matter. It seemed reasonable that since maternity benefit was given for the purpose of enabling the woman to pay for additional nourishment and expense, she should pay for the expenses incurred in the maternity hospital. It was stated by an Edinburgh representative that the matter had been before the Edinburgh Town Council recently, because a large number of the inmates in the maternity hospital of that city paid nothing, although it was believed that many of them were able to pay. The Edinburgh corporation, it was believed, would approve of legislation, and it was finally resolved to approach the Board of Health on the subject.

## Ireland.

#### ROYAL VICTORIA HOSPITAL, BELFAST.

Mr. S. T. IRWIN, F.R.C.S.I., delivered the opening address of the new session in the King Edward Memorial Hall of the Royal Victoria Hospital, Belfast, on the morning of October 19th. Mr. Mitchell, chairman of the visiting staff, presided, and there was a large attendance of the staff and of students. The lecturer pointed out the dependence of voluntary hospitals on the lay press to educate the public, and hastened to acknowledge the value of the help the hospital had always received. He recalled the days in the old Royal Hospital in Frederick Street, where he was one of the four resident pupils in 1903 when it moved to its present quarters. The old hospital was founded in the year of Waterloo and opened in 1817, and had been added to from time to time. Chiefly by the exertions of the late Lord Pirrie, and by his wife, their president, Lady Pirrie, the present hospital was founded and opened free of debt in 1903 by his late Majesty King Edward VII; the originators had the courage of their convictions, and it was planned and built on the latest designs, and had proved a great success; it had 204 beds, and His Grace the Governor would next day (October 20th) open new wards to bring it up to 435 beds. The out-patients were then 22,585; they now numbered 41,024. The visiting staff had increased from 17 to 37; the residents from 4 to 14; and the nursing staff from 60 to 150. There were now a range of laboratories, a biochemistry department, and large x-ray and dental departments. Some of these existed in a very immature and undeveloped condition before; now they were flourishing and in full order, and, indeed, already overworked. Mr. Irwin drew attention to the value of these later and more scientific methods of examination and of treatment in the prevention of the chronic invalidism so prevalent in former years, as well as in the reduction of mortality; this could be well illustrated by the study of the protean ravages of tubercle. The lecturer, on behalf of the staff, welcomed all students, senior and junior, to their hospital studies. The most striking difference from his student days was the large proportion of women, and he paid a graceful compliment to their hard work, steadiness, and conscientiousness, although, as an orthopaedic

surgeon, he could not approve the still popular high heel and narrow toe of the shoe. Dr. Morrow proposed and Mr. Howard Stevenson seconded a vote of thanks to Mr. Irwin, which was passed with acclamation.

The extensions of the Royal Victoria Hospital, Belfast, were formally opened by the Duke of Abercorn, Governor of Northern Ireland, on October 20th. There was a large and representative gathering. Viscountess Pirrie, the president of the hospital, who was in the chair, called upon Professor J. A. Lindsay, M.D., chairman of the board of management, who, after thanking the Governor of Northern Ireland for having kindly consented to inaugurate the extensions, spoke of the pleasure those present felt in seeing in the chair their honoured and beloved president, Viscountess Pirrie, to whom and to the late Lord Pirrie, the hospital owed so much, both at its inception, through its course of the last twenty-three years, and now in the large extensions. Lady Pirrie had been its constant and generous friend, ever mindful of its interests, ever sympathetic, and ever helpful. A pamphlet which had been prepared and was in the hands of those present gave full information on the work of the last three years; every department had shared in the benefits, and additional beds, a new nurses' home, three new operating rooms, and new classrooms had been provided, as well as additional accommodation in the ophthalmic, x-ray, pathological, biochemical, electrotherapeutic, and dental departments; more room for offices, kitchens, laundry, workshops was afforded, and a new gate lodge had been erected. This long list accounted for the heavy expenditure, amounting to £130,000. There was no finality in hospital construction; all recent improvements had been adopted. There was a demand to-day for paying departments in voluntary hospitals, and they were the rule in Canada and the United States. It was hoped that in the near future it would be possible to meet this want. The hospital was specially indebted to the superintendent, Colonel Forrest, who had given much practical assistance and made many valuable and fruitful suggestions. Viscountess Pirrie expressed their great pleasure in welcoming the Governor of Northern Ireland, and regret at the absence of the Duchess; she referred also to the prevision of those responsible for the hospital at its foundation, who made plans to meet the essential developments which experience and success brought; she looked upon the demand for enlargement as proof that the board and medical staff continued to hold in increasing measure the confidence and goodwill of the public; she referred to the munificent legacy of the late Mr. Musgrave, which had rendered it possible to build the new nurses' home. The Governor, in declaring the extensions open, paid a graceful tribute to the late Lord Pirrie and to Lady Pirrie. He stated his great pleasure in seeing such advances in hospital work and construction, and the generosity of the public in enabling the work to be carried on to such a successful issue. Dr. Livingstone, Vice-Chancellor of the Queen's University, proposed a vote of thanks to His Grace, and gave some figures of the medical school, and of the course of instruction in the classrooms and in the hospital. This was seconded by Mr. A. B. Mitchell, F.R.C.S.I., chairman of the medical staff, who said that these improvements enabled the staff to carry out their work with increasing accuracy and efficiency. His Grace responded. After the opening ceremony a tour of inspection was made.

#### APPOINTMENT OF COUNTY MEDICAL OFFICERS OF HEALTH.

The Minister of Local Government and Public Health has addressed a circular letter to all county councils in the Irish Free State, in the course of which he states that the Executive Council has appointed Local Appointments Commissioners in pursuance of the Local Authorities (Officers and Employees) Act, 1926, and that he will not consent to any appointment made contrary to the provisions of this Act. The Minister further states that it now devolves on the county council, in conformity with the terms of Section 6 (1) of that Act, to request the Local Appointments Commissioners to recommend to them a person for appointment as county medical officer of health. Having regard to the urgent necessity for making these

appointments, each county council should at the earliest possible moment take the whole question into consideration as recommended in the circular letter above mentioned, and should fix a suitable salary for the post. An application should at the same time be addressed by it to the Local Appointments Commissioners to recommend a person or persons for appointment as a county medical officer of health.

### A GOOD DIET AND A BAD ONE.

SIR,—It is to be hoped that doctors will take seriously to heart the lesson taught by Colonel McCarrison's paper published in the JOURNAL of October 23rd (p. 730). Of recent years we have heard much of the work done on experimental dietetics—of the calorie value of different foods, of the dangers of vitamin starvation, and the like—until we have almost come to suppose that it is impossible to construct a healthy dietary without calling the laboratory expert to our aid. No doubt experimental findings have been helpful in clarifying ideas concerning the evils attaching to many of our modern highly artificial foods, but surely the best way to arrive at the diet most suitable for man is by studying that of healthy races living under primitive conditions; by healthy races I mean such as are well set-up and conspicuously exempt from such disorders as tonsillitis, adenoids, dental caries, appendicitis, and cancer.

Colonel McCarrison cites instances of such races, and describes their diet. We seem justified in assuming that if, from early years, we all adopted a similar diet the national standard of health and physique would be greatly improved, although, owing to our necessarily more sedentary life, our standard would still fall below that of these remarkable races.

Much as we can learn from studying the diet of comparatively primitive agricultural peoples, I venture to think that we can reach an even deeper level of truth concerning human dietetics by studying the diet of the pre-agriculturalists. It is possible to trace out precisely the changes which have taken place in the diet of the evolving man from the pre-human anthropoid phase to that of late pre-agricultural man. To me it does not seem possible for us to have a firm grasp of the fundamentals of human dietetics until we have learnt the lessons to be learnt from a study of man's diet at the late pre-agricultural phase; for let us not forget that civilized man is innately much the same to-day as when man first began to cultivate the soil, and that, from the standpoint of evolution, this phase was but as yesterday.

What do we find when we examine the diet of pre-agricultural man as he exists to-day? We are told that bread is the staff of life; pre-agricultural man has no cultivated cereals of any kind; and therefore no bread, whole-meal or other. We are often told of the value of sugar as a food: pre-agricultural man has no concentrated sugar save an occasional taste of wild honey. Again, we are told that non-human milk is a necessity for children after the weaning period: pre-agricultural man has never tasted milk other than his mother's, and knows nothing of butter or cheese. Needless to say, he is equally ignorant of tea, coffee, and alcohol. The cardinal truth to grasp is that, on a diet which, to all intents and purposes, contained no one of these items, man evolved from a speechless ape to a being capable of abstract reasoning, and during all that time maintained a standard of physical fitness far beyond that of civilized man of to-day.

A further important particular wherein the food of pre-agricultural man differs from that of modern man is in the comparative paucity in starch, and in the abundance of raw vegetable foods requiring vigorous mastication as compared with the richness of modern dietaries in soft starchy ingredients. Man evolved as a hunter. He subsisted on animal food supplemented by carefully selected raw vegetable foods until the discovery of cookery. With this discovery (with which, by the way, pre-agricultural man has been familiar for thousands of years) he greatly augmented his vegetable food, notably his supplies of starch.

It must not be supposed that I am suggesting we should all return to the diet of pre-agricultural man. I merely wish to insist that we can correct some of our notions concerning human dietetics by studying the dietetic habits of primitive peoples—above all, of the pre-agriculturists, now almost extinct. By a judicious study of the diet of primitive races now living, it is possible to construct agreeable varieties of diet which, if generally adhered to, would raise in a surprising degree the national standard of health and physique and increase to a corresponding extent the fund of human happiness.—I am, etc.,

London, W., Oct. 23rd.

HARRY CAMPBELL.

## MINER'S NYSTAGMUS.

SIR,—I note that in Mr. Percival's letter (October 23rd, p. 758) he states that he certainly agrees with Dr. Ingram-Johnson's theory (October 2nd, p. 615) that the position at work and consequent strain of the external muscles of the eyeball is a very important factor in the causation of miner's nystagmus. At the same time he is "not disposed to accept" my view (October 9th, p. 664) that miner's nystagmus is caused by interference with vestibular function. He omits to state, however, that before coming to this conclusion I too expressed the opinion that this interference was primarily due to the abnormal posture of the body adopted by the miner and to the prolonged or intermittent strain of the muscles of the eyeball.

The important nerve structures which would be affected in such a case would be the vestibular reflex arcs; for example, (1) that constituted by the fibres of the medial longitudinal bundle which pass from the vestibular nucleus to the oculomotor, trochlear, abducent, and accessory nuclei and to the motor cells of the cervical spinal cord. (2) The auxiliary arcs formed by the oculomotor, trochlear, abducent, accessory, and cervical spinal nerves which supply the muscles which move the head and eyes. By means of these arcs combined movements of the head and eyes (for example, nystagmus) are regulated in response to vestibular stimulation. (3) Through the vestibulo-spinal tract a reflex arc is established between the vestibular sense organ and the skeletal musculature, thus bringing the primary motor neurones under the reflex control of the vestibular apparatus. (4) Through its connexions with the vestibular nucleus, the cerebellum is able to influence the descending vestibulo-spinal tracts and the spinal neurones.

These manifold but important connexions have led me to offer what I still think is a sound physiological and anatomical explanation of how the phenomenon is evolved, and it must be admitted that the theory is more than plausible, not only in connexion with the nystagmus itself but also in connexion with the other symptoms. I can think of no other nerve structure, "deep-seated" or otherwise, whose connexions could possibly fill the bill more completely than the nucleus of Deiters.

As the incidence of miner's nystagmus seems to vary in different pits some contributory cause must be looked for. Such a cause may be bad light, or it may be toxic owing to inhalation of foul air in ill ventilated mines, or there may be an hereditary tendency, as an hereditary type of nystagmus is described which is passed from mother to child and which shows no ocular defect. Coal-mining is usually a familial occupation, so statistics of the familial incidence of miner's nystagmus would be of great interest in this connexion.

Mr. Percival's remarks concerning the types of nystagmus met with are of great clinical interest, but no matter what form the nystagmus assumes, it cannot take place without the medium of the vestibular nucleus.—I am, etc.,

Manchester, Oct. 23rd.

RICHARD I. POSTON, M.D.

## SANATORIUM TREATMENT.

SIR,—Dr. Stocks in his reply (October 16th, p. 713) misses the point of my criticism. He assumes that treatment is completed in the sanatorium, and that similar remedies are not employed in "non-sanatorium" cases; also that the duration of treatment in the sanatorium is a measure of the duration of sanatorium régime; none of which statements are correct. If he were trying to test

the value of salicylates in rheumatic cases, would he think it fair to include patients who had only had a few doses, and to exclude others who had had a full course elsewhere?

Sanatorium treatment is not so much a remedy as a manner of life, with precautions and special remedies learnt from clinical experience, and employed as occasion arises. The same treatment is adopted outside the sanatorium by every up-to-date doctor, though under difficulties and with the omission of unattainable remedial measures. There is no clear-cut distinction between Dr. Stocks's groups.

Length of stay, taken alone, is no measure of the completeness of the course: four months may be enough for safety in one case, and utterly insufficient in another; but in every case the ultimate result will depend mainly upon the conditions of life—including such matters as good sense and perseverance of the patient, a careful wife, no long spell of unemployment, as well as many others which are not all included in Dr. Stocks's list. And the effect is cumulative. When all or most of these conditions are favourable tuberculosis officers will attempt home treatment; so that the "home treated" are likely to be a more favourable group than the "hospital and sanatorium treated." Nearly every bad case is sure to be sent for treatment to an institution at some time or other, and so to be included in Dr. Stocks's "sanatorium treated" group. Of over 2,000 sanatorium patients of whom I have notes, not more than 25 per cent. are early favourable cases.

So long as patients admitted to sanatoriums consist predominantly of those who are no longer in the most favourable stage, and treatment there is limited to the average time available for all collectively, so long will sanatorium treatment be regarded as a failure by the "man in the street." A better policy would be to treat early favourable cases for prolonged periods, or to provide sanatorium conditions for them elsewhere while at work; and to treat the less favourable cases elsewhere, in some place where elementary requirements with medical attention can be provided.—I am, etc.,

Farnham, Surrey, Oct. 19th.

F. R. WALTERS.

SIR,—Accustomed as I have been to regard statisticians as men who strive after the attainment of accuracy and truth, I feel a sense of keen disappointment when I find Dr. Percy Stocks (October 16th, p. 713) resorting to a controversial device which I had associated in my mind with ordinary unscientific men. The device is that of representing me as saying what I did not say, and then replying to the misrepresentation.

I did not object "that the presence or absence of tubercle bacilli in the sputum was not made the indispensable criterion for diagnosis." Nor did I "speak of the finding of bacilli as a *sine qua non* in diagnosis." What I said was that in my experience "among patients suffering from pulmonary tuberculosis who have survived for more than six months from the time when they first came under observation, there has been an enormous difference, as regards both survival and recovery of working power, between cases in which tubercle bacilli were found in the sputum and those in which, though sought for, they were not found." Clearly this implies that I acknowledge that there are cases of pulmonary tuberculosis in which tubercle bacilli, though sought for in the sputum, are not found.

My contention still holds good that in any investigation of this kind T.B.+ and T.B.— cases should be kept quite separate, and that data which do not permit of this being done should be avoided. Among the Belfast cases on which Dr. Stocks's investigation was based, the percentage of T.B.+ cases is so small that I cannot help thinking that there was a want of thoroughness in looking for tubercle bacilli; and that, if systematic search had been made, the bacilli would have been found in a considerable, but unknown, percentage of the cases now regarded by him as T.B.—. This is on the assumption, which I have adopted throughout, that all the cases under consideration were actually cases of pulmonary tuberculosis. Take, for instance, the figure given by Dr. Stocks for female patients in the L<sub>1</sub> stage sent to sanatoriums of the Lancashire County Council from 1914 to 1923. Of these, he says, 29 per cent. "had the diagnosis confirmed in this way." And compare.

this with 4.2, the corresponding percentage in the Belfast cases. Again, taking all the county Down cases diagnosed by my assistants and myself as pulmonary tuberculosis from 1913 to 1924, tubercle bacilli were found in the sputum in 62.2 per cent. The percentage varied from year to year; the highest, 77.3 per cent., being the 1917 figure; and the lowest, 53.6 per cent., the 1920 figure. The corresponding figure for the Belfast cases used in Dr. Stocks's investigation was about 10 per cent.

This uncertainty as to the proportion of T.B. + cases in each of the subgroups made by Dr. Stocks from the Belfast data is what prevents me from having any confidence in the conclusions based on these data.—I am, etc.,

Knock, Belfast, Oct. 18th.

JOHN R. GILLESPIE.

## CONTAGIOUS BOVINE ABORTION AND UNDULANT FEVER.

SIR,—Owing to absence from London, my attention has only now been drawn to an article in your issue of August 21st (p. 353). In it I am credited with finding two cases of undulant fever in England in people who had never left the country. This is an error. My work consisted in showing that the milk and blood serum of some London cows contained agglutinins for the *Micrococcus melitensis*.<sup>1</sup> This was one of the first links in the chain of evidence that was gradually built up to show the close relationship between the organisms of bovine abortion and of undulant fever in man.—I am, etc.,

J. C. KENNEDY,  
Colonel, R.A.M.C.

London, S.W.1, Oct. 22nd.

## Medico-Legal.

### A MEDICATED WINE.

In a Divisional Court of the King's Bench Division, on October 19th, the Lord Chief Justice, and Salter and Talbot, JJ., upheld a decision of the Brighton justices, that "Wincarnis with quinine" was intoxicating liquor within the meaning of Section 65 of the Licensing (Consolidation) Act, 1910, and that it was an offence to sell it without a justices' licence.

The question whether "Wincarnis with quinine" was an intoxicating liquor or a patent medicine arose on a case stated by the Brighton justices. The appellant, H. J. Sharp, a chemist and druggist of Edward Street, Brighton, had been convicted on an information preferred by a police superintendent of selling by retail, on January 27th, 1926, certain intoxicating liquor—namely, wine known as "Wincarnis"—he not then being the holder of a justices' licence, and had been fined £1, plus the cost of the analyst's fee.

#### Case Stated by Brighton Justices.

The case stated that the appellant was the holder of an excise licence to sell patent medicines. A police constable a day or two before January 27th entered the appellant's shop and asked for a bottle of "Wincarnis" and was told that it was not stocked, being referred to a wine merchant. On January 27th, however, the appellant sold to this policeman a bottle of "Wincarnis with quinine" for 3s., several bottles being displayed in the shop. The wrapper and bottle each had three labels containing the following words: "made with choice wine," "contains one grain of quinine to the ounce to meet the requirements of the Board of Inland Revenue," "contains 28 per cent. of proof spirit," "strongly recommended by the medical faculty," "dose—one tablespoonful to two tablespoonfuls may be taken three times a day," "bottle not to be shaken as there is occasionally a little sediment from the wine after bottling." On the wrapper was an excise label showing that a medicine stamp duty of 6d. had been paid on the contents. The liquid was found on analysis to contain 27.99 per cent. proof spirit (equivalent to 13.99 per cent. of alcohol) and 1.2 grains of quinine per fluid ounce. The justices found that the liquid in the bottle was an intoxicating liquor; was medicated, and tasted of quinine; that according to the standard of quinine wine in the *British Pharmacopoeia* a mixture containing one grain or more of quinine to the fluid ounce was considered a medicine; that sherry was also contained in the *Pharmacopoeia*; that a good port wine contained 30 per cent. of proof spirit; that the dose of quinine as prescribed by the *Pharmacopoeia* was from one to ten grains; that with a full dose of ten grains half a pint of the liquid would have to be taken.

The appellant's contention was that "Wincarnis with quinine" was not an intoxicating liquor within the meaning of the Licensing Acts, whilst the respondent's contention was that the labels on the wrapper and bottle were prima-facie evidence that the liquid was made with wine, that no evidence was called to rebut it, and that it was intoxicating liquor within the meaning of Section 65 of the Licensing (Consolidation) Act, 1910. The justices found that the liquid sold was wine, and convicted the appellant.

Mr. Roland Oliver, K.C., and Mr. Llewellyn appeared for the appellant; Mr. E. J. Rimmer appeared for the respondent.

<sup>1</sup> *Journal of the R.A.M.C.*, January, 1914.

### The Appellant's Case.

Mr. Oliver said that if the conviction were right it would be necessary for every chemist and druggist who sold that or similar medicated wines to hold some sort of licence to enable them to do so. The Excise authorities had never taken any action on the matter. This prosecution was taken by the police. He agreed that before quinine was added to the liquid it was probably some sort of port, but as it stood it was not the sort of stuff people would want to drink as a beverage. Counsel quoted Section 110 and Section 111 (2) of the Licensing (Consolidation) Act, 1910, and Section 3 of the Spirits Act, 1886, and argued therefrom that if he could show that "Wincarnis with quinine" was not a wine; it could only come under the definition of "spirituous liquor," and would be exempt as "spirits made up in medicine." One must have regard to the two objects of the licensing law: the due preservation of public order, and the safeguarding of the revenue. The passage in *Paterson's Licensing Acts* saying that a wine licence was required for the sale of medicated wines was, in his submission, wholly wrong. He relied on the finding of the justices that it tasted of quinine, and cited *Attorney-General v. Bailey* (17 L.J., Ex. 9).

### The Respondent's Case.

Mr. Rimmer argued that the fact that it was not the practice of the Excise authorities to require chemists to take out an excise licence for selling that preparation was a purely department rule not in any way binding on the prosecution. It was immaterial that quinine wine was mentioned in the *British Pharmacopoeia*, so was sherry, and it could hardly be argued that sherry was not a wine. The admixture of non-alcoholic liquor with a wine did not make it cease to be a wine and become a spirit. If that were so, a person who had a wine licence could sell port but could not sell "Wincarnis with quinine," or could sell claret but not claret cup. The distinction between "wine" and "spirits" contemplated by the Act was that which the man in the street would make. "Spirits" implied distillation and "wine" fermentation without distillation. If before the admixture it was a fermented liquor in the sense of being wine, it remained after the admixture a fermented and not a spirituous liquor.

Counsel was stopped by the court.

### Dismissing Appeal.

The Lord Chief Justice, in his judgement, said the only question was whether the liquid that was being sold was wine. If it was, then its sale by retail without a justices' licence was illegal. It was possible to conceive a problem not medical or chemical, but of a commercial kind—namely, how to command a large sale of inferior port wine at a comparatively high price with the help of a great number of persons who do not commonly sell wine, and especially a great number of purchasers who might hesitate to buy or drink wine if it were offered to them as such. The answer to that problem might conceivably be the putting of a little medicine in wine and selling it in chemists' shops. That might be a matter which deserved the attention of the Legislature. Upon the facts of the case, how could it be said that there was no evidence upon which the justices could hold as they did? It might well be that the commercial problem was how to put enough medicine into wine to make it cease to be wine for the purposes of argument, without putting in so much medicine as to make it unpalatable to men, women, and children, and especially women who on being told they suffered from nervous diseases were not at all disinclined to find a plausible excuse for drinking port at 11 o'clock in the morning. His lordship thought there was abundant material upon which the justices could find as they did.

Salter and Talbot, JJ., concurred.

## The Services.

### NAVAL MEDICAL COMPASSIONATE FUND.

At the quarterly meeting of the directors of the Naval Medical Compassionate Fund, held on October 19th, when Surgeon Vice-Admiral Sir Joseph Chambers, K.C.B., C.M.G., Medical Director-General of the Navy, was in the chair, the sum of £114 was distributed among the several applicants.

### DEATHS IN THE SERVICES.

We much regret to record that among the names of those missing from H.M.S. *Valerian*, which foundered in a hurricane, is that of Surgeon Lieutenant Colin Joiner, R.N. He graduated M.B., Ch.B. Aberd. in 1924, received his commission on September 1st, 1924, and was appointed to the *Valerian* on April 29th, 1926. He was a member of the British Medical Association.

Lieut.-Colonel Sidney Herbert Carter, R.A.M.C. (ret.), died suddenly in a nursing home at Brighton on October 15th. He was born in county Antrim on March 14th, 1848, and was educated at Trinity College, Dublin, where he graduated B.A. and M.D. in 1870. He entered the R.A.M.C. as surgeon on September 30th, 1874, became surgeon lieutenant-colonel after twenty years' service, and brigade surgeon lieutenant-colonel in November, 1897. He retired in January, 1903. While serving in South Africa, as principal medical officer of a division, he was granted the local rank of colonel from April 15th, 1900. He served in the Afghan war of 1878-80, when he was present at the battle of Ahmed Khel, and received the medal with a clasp; in the Egyptian war of 1882, at the battle of Tel-el-Kebir (medal with clasp, and Khedive's bronze star); in the Tirah campaign on the North-West Frontier of India, in 1897-98, on the lines of communication (frontier medal with two clasps); and in South Africa, 1899-1901, when he took part in the defence of Ladysmith, was twice mentioned in dispatches, and gained the Queen's medal with five clasps.

Major Charles Stewart Lowson, Indian Medical Service (ret.), died in London on October 9th. He was born at Lille on February 19th, 1874, the son of James Lowson, and was educated at Glasgow, where he graduated M.B. and C.M. in 1896. After serving as a civil surgeon in the R.A.M.C. from October 17th, 1898, to July, 1899, he entered the I.M.S. as lieutenant on July 27th, 1899, becoming major after twelve years' service, and retiring on July 27th, 1917.

## Universities and Colleges.

### UNIVERSITY OF OXFORD.

At a congregation held on October 21st the following medical degrees were conferred:

B.M.—W. H. Hudson, E. L. Fothergill.

#### Radcliffe Prize.

The next award for the Radcliffe Prize will be made in March, 1927. The prize, of the value of £50, is awarded by the Master and Fellows of University College every second year for research in any branch of medical science comprised under the following heads: human anatomy, physiology, pharmacology, pathology, medicine, surgery, obstetrics, gynaecology, forensic medicine, hygiene. The prize is open to all graduates of the university who have proceeded, or are proceeding, to a medical degree in the university. Candidates must not have exceeded twelve years from the date of passing the last examination for the B.A. degree, and must not, at the date of application, be Fellows on the Foundation of Dr. John Radcliffe. Candidates must send in their memoirs to the Secretary of Faculties, at the University Registry, on or before December 1st, 1926. No memoir for which any university prize has already been awarded is admitted to competition for the Radcliffe Prize; and the prize will not be awarded more than once to the same candidate.

### UNIVERSITY OF CAMBRIDGE.

The following candidates have been approved at the examination indicated:

D.P.H. and Hy.—Both Parts: † L. Dunlop, B. Ethirajulu, \*N. E. Gold-worthy, R. A. N. Henein, F. Hilmy, Martha H. Lawler, W. Omar, H. B. Porteous, T. C. Puri, J. S. Smith, Margaret A. C. Symon, †A. W. al Wakil.

\* Distinguished in Part I.

† Distinguished in Part II.

### UNIVERSITY OF LONDON.

Dr. PERCY STOCKS, medical officer to the Galton Laboratory since 1921 and Lecturer in Vital Statistics and Epidemiology at University of London, was elected University Reader in Medical Statistics, on October 20th a resolution was passed by the Senate's high appreciation of the work accomplished by Sir Cooper Percy during his tenure of the post of Principal Officer, to which he was appointed in 1920.

### UNIVERSITY COLLEGE HOSPITAL.

THREE lectures in the history of medicine, illustrated by lantern slides, will be delivered at University College Hospital Medical School, by Dr. Charles Singer, on Fridays, November 5th, 12th, and 26th, at 4.15 p.m. The first will deal with the history of scarlet fever, the second with the sweating sickness, and in the third Dr. Singer will discuss some points in the history of hygiene. The lectures are open to all medical students of the University of London.

### UNIVERSITY OF EDINBURGH.

A GRADUATION ceremonial was held in the Upper Library Hall on October 23rd, when the following degrees were conferred:

M.B., Ch.B.—A. I. Barron, O. D. Beetham, H. Caplan, C. W. Clayton, B. G. T. Elmes, W. A. Erskine, A. T. Forbes, W. G. Hardie, J. D. Horsburgh, W. D. Jackson, J. M. L. Johnston, J. J. Mason, D. O. Peters, G. Phillips, E. M. Robertson, P. M. Scott, P. Seager, E. M. Smith, H. T. Stirling, C. B. Craig, A. I. Messer, Captain J. B. de W. Murray, O.B.E., L.C.S.D., A. C. Murray, Agnes F. Turner.

### ROYAL COLLEGE OF SURGEONS OF ENGLAND.

#### CALENDAR FOR 1926-27.

The College Calendar for the current year has been issued. It includes, as usual, a report of the proceedings of Council during the past twelve months, together with lists of officers, fellows, members, and diplomates, and the customary historical and official information. In the period under review 63 diplomas of fellowship were issued, including 2 to medical women; 768 diplomas of membership, including 144 to women; and 202 licences in dental surgery, including 9 to women. The following diplomas were granted jointly with the Royal College of Physicians: Public Health, 32; Tropical Medicine and Hygiene, 52; Ophthalmic Medicine and Surgery, 51; Psychological Medicine, 18; Laryngology and Otology, 15. In compliance with a request from the British Dental Association, the Council decided to institute a gown for licentiates in dental surgery.

The subject of the Jacksonian Prize for 1927 is "The Pathology, Diagnosis, and Treatment of Bronchiectasis and Abscess of the Lung." No essays were received in competition for the prize in 1925.

The Supplemental Charter in the form prayed for by the

College was approved by the King in Council on July 26th, 1926. In order to carry out the provisions of the new Charter alterations will be required in certain by-laws, and a committee has been appointed to consider and report to the Council on the proposed changes.

The financial report states that the income of the College, exclusive of income from Trust Funds, amounted to £43,630, or £4,397 less than in the previous year. The decrease is mainly accounted for by a falling off in fees for the Conjoint Diploma and for the L.D.S. The total expenditure amounted to £36,123, or £5,214 less than in the previous year; of this decrease £2,562 was in respect of examination expenses. The balance on the revenue account amounted to £7,507, or £817 more than the sum realized in the previous year. While the net result of the current year is not likely to be so favourable, there is reason to expect a substantial balance to the good.

The Conservator's report records the appointment of Mr. Cecil F. Beadles as pathological curator in succession to the late Professor S. G. Shattock. Much progress was made in the revision of the collections illustrating the injuries and diseases of special systems and organs of the body; also in the re-cataloguing of specimens illustrating special pathology, and in the cataloguing of the Army Medical Collection now almost completed. Mr. Alban Doran completed his task of preparing a descriptive catalogue of the collection of surgical and other instruments, and the labelling and arrangement of specimens has been greatly improved under the guidance of Mr. C. J. S. Thompson. The scheme for extending the odontological collection, under the honorary curatorship of Sir Frank Colyer, is now on the point of completion. During the period under review more than 11,000 students and visitors used the Museum. The number of readers in the library was 6,350, and the Librarian in his report states that the supply of books and periodicals was well kept up during the year, works bearing on surgery and the contents of the Museum being chiefly provided. A useful addition to the Calendar is an inset plan of the floor of the library, indicating the position of periodicals and works of reference.

### ROYAL COLLEGE OF SURGEONS OF EDINBURGH.

At the meeting of the Royal College of Surgeons of Edinburgh, held on October 20th, Dr. Arthur Logan Turner was re-elected President for the ensuing year, Sir David Wallace, C.M.G., D.L., Vice-President, and Mr. Alexander Miles, LL.D., F.R.C.S.E., Secretary and Treasurer.

The following thirty-six successful candidates out of eighty-three entered, having passed the requisite examinations, were admitted Fellows:

A. W. Allum, R. Armstrong, W. E. Barrie-Adhead, K. D. Bhaye, G. S. A. Bishop, A. Callan, R. E. D. Cargill, J. R. Corneish, D. R. Cramb, A. Gillies, K. H. Gillison, Major W. T. Graham, R.A.M.C., R. J. B. Hall, H. A. H. Harris, C. V. Krishnaswami, G. E. Larks, J. G. Lynch, C. S. Macdonald, W. B. McKelvie, Surgeon Commander J. A. Maxwell, R.N., B. Moore, H. W. Nash, R. W. Payne, J. H. Pilkey, J. L. R. Plimmer, W. J. Robertson, P. Roux, J. Scott, T. Sprunt, J. P. Stewart, S. H. Tan, P. A. Treahy, I. A. Tumarkin, J. R. Wells, T. A. Weston, L. M. Zinck.

### CONJOINT BOARD IN SCOTLAND.

The following candidates have been approved at the examination indicated:

FINAL EXAMINATION.—*Medicine*: D. J. McKenna, R. A. Paton, D. Ross, E. P. Kelly, S. P. B. Gunawardana, B. A. Van der Gert, S. A. Gunawardana, E. A. Y. MacKeown, P. J. Bourke, *Surgery*: A. E. Larks, J. G. Buchanan, A. Rouchouk, S. B. Cartheagassam, A. Cowan, *Midwifery*: J. D. Cooper, D. F. Jayamaha, K. Dhar, R. A. Paton, S. Callier, D. Ross, A. B. Gilston, Lucy W. Macdonald, Elizabeth Bell, B. A. Van der Gert, S. A. Gunawardana, A. Rouchouk, H. T. J. Abeyesundere, L. M. de Silva, P. J. Bourke, S. R. Cartheagassam, J. E. Mulholland, K. Palli, A. R. Cowan, H. O. Duncan, D. F. Jayamaha, A. W. Campbell, M. Clifton-Mitchell, W. R. B. MacGibbon, Mary E. J. Magee, L. M. Green.

Of ninety-seven candidates entered the following, having passed the Final Examination, were admitted L.R.C.P.E., L.R.C.S.E., L.R.F.P. and S.G.:

W. G. H. Allen, O. D. Beetham, P. R. C. Peterson, N. M. Eadie, A. G. Farquharson, A. E. F. L. Forbes, W. L. G. Jewitt, S. A. B. Hosang, J. A. Mains, T. A. P. Wynter, D. Zimmerman, J. G. Currie, E. M. R. Swami, G. M. Fox, R. D. Kerr, J. V. O'K. Murphy, B. W. Perera, C. Gurusamy, H. B. Martin, D. B. J. de Silva, H. S. Kent, R. B. Werden, M. B. Stungo, D. S. Ellis, J. Hendry, A. S. Pool, J. J. S. F. e Souza, C. H. A. S. B. Panlickpulle, S. W. Charles, A. W. Scott.

D.P.H.—  
Fior  
M. J  
E. J  
Philomena R. Whitaker, J. Douglas.

### SOCIETY OF APOTHECARIES OF LONDON.

The following candidates have passed in the subjects indicated:

*Surgery*—H. J. Fordham, R. C. Glover, W. Johnson, R. I. Richards, H. Rundstrom.

*Medicine*—A. Heukamp, W. Howard, T. W. Risley, W. D. Williams. *Forensic Medicine*—J. R. S. Bowker, A. Heukamp, W. E. Ivers, S. Jenkins, T. W. Risley, V. K. Samy, W. D. Williams, R. W. Wood.

*Midwifery*—H. M. de Hartog, B. D. Jain, A. W. Marsden, C. E. Nicholas, J. Pattis, D. K. Reynolds, E. H. Waller, W. D. Williams.

The diploma of the Society has been granted to Messrs. R. C. Glover, A. Heukamp, W. Johnson, C. E. Nicholas, J. Pattis, and R. I. Richards.

## Obituary.

W. H. WHITE, M.D.,

Consulting Physician, Royal Hospital for Diseases of the Chest.

DR. WILLIAM HENRY WHITE, whose death occurred suddenly on October 22nd, was born at Wexford in 1849 and educated in Ireland. He graduated at Trinity College, Dublin, ultimately becoming M.R.C.P.Lond. When he came to England he practised at Westbury, Shropshire, but after a few years he found that the work of a very great and growing practice was too much for his health. After a rest he settled at 43, Weymouth Street, and for forty-five years, down to the day of his death, was seeing patients. Dr. White belonged to the old school of practitioners. Very definite in diagnosis and perhaps somewhat dogmatic, he had a great hold on his patients. His appearance was striking, and his personal magnetism as great with the poor as with the rich, largely owing to his cheerfulness and geniality. He was for many years physician to the Royal Hospital for Diseases of the Chest and to the St. Marylebone Dispensary. His treatment of disease was intensely practical; he was quick to discard useless methods. His friends will ever remember him for his charm, kindness, and sympathy. He was a great lover of horses, for many years a familiar figure in the Row, and only a few years back did he at last give up driving his own pair on his rounds. Another favourite pastime was yachting at Falmouth and along the south coast. The death of his wife in January last, just after their golden wedding, was a terrible blow to him, from which he never recovered. He is survived by his two children, a daughter and son, Norman.

We regret to record the death of Dr. ROBERT PARRY, a leading practitioner of Carnarvon, at the age of 71. He was a native of Merionethshire, and received his education at Owens College, Manchester, and Guy's Hospital Medical School. He obtained the diplomas of L.S.A. in 1878, M.R.C.S.Eng. in 1879, and L.R.C.P.Lond. in 1882, and graduated M.B.Lond. in 1882. In 1883 he started practice in Carnarvon, and soon afterwards began to take an active part in the public life of the district. He was for nearly forty years a member of the town council, was mayor from 1897 to 1899, and in 1921 his name was added to the roll of freemen. He had also served as chairman of the County Council and chairman of its Health Committee, and was a member of the Carnarvonshire Insurance Committee and of the Joint Sanitary Committee for the county. He was a justice of the peace for the borough and county of Carnarvon. His professional appointments include those of medical officer to the Carnarvon Union Infirmary, and surgeon to the police and to the local prison. For many years Dr. Parry had been a loyal and zealous member of the British Medical Association, and at the time of his death was a member of the North Wales Branch Council and of its Executive Committee; he was president of the North Wales Branch in 1901. He was highly esteemed by his colleagues, and his guidance in professional difficulties was much appreciated. At the funeral there was a large assembly of mourners, including representatives of all the public bodies on which Dr. Parry had served, and a great many medical men. He is survived by his widow, three sons, and two daughters; two of the sons are members of the medical profession.

Dr. CHARLES CLEMENT LAPAGE, who was for forty-two years in practice at Nantwich, Cheshire, died on October 14th after a short illness. He was a native of Leeds, and was educated at Leeds and Magdalene College, Cambridge. He obtained the diplomas M.R.C.S.Eng. in 1876 and the L.S.A. in the next year; he graduated M.B.Cantab. in 1882, and in the same year proceeded M.D. After holding the appointment of assistant house-surgeon to the Leeds General Infirmary he commenced private practice in Nantwich, and retired in 1919. In addition to his private practice he was consulting phy-

sician to the Brine Baths Hotel, and took an active part in the voluntary medical work of the town. He was medical officer to the Red Cross detachment before the war, and served throughout it as medical officer to the Nantwich V.A.D. Hospital. Dr. Lapage was for many years a member of the British Medical Association, and he was also very active in ambulance work, being well known over the Cheshire district as an examiner and lecturer for the St. John Ambulance Brigade. He took great interest in athletics, and in his university days was prominent in many forms of sport. This interest he retained as far as possible when he went to Nantwich, where he was well known in the hunting field and as a supporter of every form of open-air life. His wife predeceased him in 1919, and he is survived by a daughter and five sons, two of whom are members of the medical profession.

The following well known foreign medical men have recently died: Dr. KAUFFMANN, oto-rhino-laryngologist, at Angers; Professor MAX KOCH, pathologist, at Berlin, aged 53; Dr. MAX HOWALD, professor of medical jurisprudence at Berlin; and Professor E. OPITZ, gynaecologist, at Freiburg.

## Medical Notes in Parliament.

[FROM OUR PARLIAMENTARY CORRESPONDENT.]

PARLIAMENT reassembled on October 25th to approve the continuance of the Emergency Regulations during November. This was done after discussion. The House of Commons sat on October 25th and 26th, but its debates did not result in any new proposals for settlement of the mining dispute, although approaches were made to the Prime Minister behind the Chair. Occasion was taken during the sittings to take the opinion of the House on certain remarks made earlier in the month by Dr. Salter in a speech at a temperance society, in which he imputed inebriety to certain members of the House of Commons. A prolonged debate ensued, during the course of which Dr. Salter repeated his allegations. Veteran members testified to the much improved sobriety of the country and of the House. A motion repudiating Dr. Salter's charges was made, but an amendment was proposed to refer the matter to a Committee of Privileges; the amendment was rejected, and the original motion adopted without a division.

The House of Commons will meet again on November 9th for the ordinary business of the autumn session. The heavy work caused by the coal stoppage and the Imperial Conference has, however, disturbed the Ministerial programme, and Mr. Neville Chamberlain does not now hope to obtain this autumn a preliminary debate in the House of Commons on the bill he is preparing for the reform of the Poor Law and the abolition of boards of guardians. He may, however, issue a draft or summary of it for examination by politicians and public authorities. The hope is that the Government will make this bill a principal item in its legislative programme of next year, but the Cabinet has not decided to do so.

## Outbreaks of Infantile Paralysis in England.

On October 25th, in reply to Mr. Ammon, Sir Kingsley Wood said that an outbreak of infantile paralysis occurred in Broadstairs this month. Fifty-three cases had been notified and there had been two deaths. The outbreak had been mainly restricted to private boarding schools and day schools in Broadstairs; three cases had occurred in convalescent homes. A medical officer of the Ministry of Health visited Broadstairs immediately, and had conferred with the medical officer of health and the local medical practitioners as to the administrative arrangements for dealing with the outbreak. Leaflets of advice had been issued and facilities for hospital isolation and disinfection provided. An outbreak in Leicester began at the end of July and reached its maximum in the week ending September 18th. The last case was notified on October 14th. There were altogether 73 cases, 6 of which were fatal. They occurred sporadically, all over the town. In no instance did more than one case occur in a household, and no one school was specially affected. Each case was personally investigated by the medical officer of health, who arranged for the necessary isolation and for treatment, either at the isolation hospital or the Royal Infirmary.

Mr. Ammon asked whether instructions were issued from the department, so far as Broadstairs was concerned, that all reports were to be suppressed and no information allowed to leak out. Sir Kingsley Wood said all notifications had been published in the official returns week by week; the council of Broadstairs—the proper body to make a statement—issued an official statement to the public generally.

## Medical News.

THE Lloyd Roberts lecture for 1926, at the Manchester Royal Infirmary, will be delivered by Dr. W. E. Gye on Tuesday, November 9th, at 4.15 p.m. The subject will be "An outline of the knowledge gained by the experimental study of cancer."

At a meeting of the Medical Officers of Schools Association, to be held at 11, Chandos Street, Cavendish Square, W.1, on Friday, November 12th, at 5 p.m., Dr. A. I. Simoy will introduce a discussion on suggestions as to the modification of the rules usually observed in the management of infectious diseases in boarding schools. (Ten 4.30 p.m.) All interested in the subject are cordially invited to attend.

A MEETING of the Medical Prayer Union will be held, by kind invitation of Dame Mary Scharlieb, M.D., M.S., at 71, Harley Street, on Friday, November 5th, at 5.30 p.m., when an address will be given by the Rev. Hubert U. Simpson, M.A., on "The doctor and religion." An intimation of intention to be present will be welcomed by the honorary secretary, Dr. Tom Jays, Livingstone College, E.10.

At the Post-Graduate Hostel, Imperial Hotel, Russell Square, W.C.1, on Monday next, November 1st, at 9 p.m., Sir James Dundas-Grant will read a paper on some clinical experiences, and on Friday, at the same hour, Dr. E. I. Spriggs will discuss diverticulosis. All medical practitioners are welcome. Dinner will be served at 8 p.m. (price 5s.) and coffee and biscuits at 10 p.m. (price 6d.).

THE Fellowship of Medicine announces that on November 4th, at 5 p.m., at the house of the Medical Society of London, 11, Chandos Street, W., Mr. C. Max Page will continue the series of lectures on surgical and medical emergencies by speaking on the treatment of fractures. On the same day, at 1 p.m., Mr. M. L. Hepburn will give a demonstration in clinical ophthalmology at the Royal London Ophthalmic Hospital. At the Royal National Orthopaedic Hospital on November 1st Mr. E. Laming Evans will give a special afternoon demonstration, starting at 3 p.m. All the above are free to members of the medical profession. On November 1st a practitioners' course in general medicine and surgery will start at the Hampstead General Hospital, with daily sessions from 4.30 to 6 p.m.; the course will last for two weeks, and a clinical demonstration will be given for the first three-quarters of an hour, followed by a lecture. On the same day a course in venereal diseases will begin at the London Lock Hospital, with clinical work each day from 1 p.m. onwards; four or five lectures will be given weekly during the four weeks of the course. At the Royal Waterloo Hospital for Children and Women a three weeks' course in medicine, surgery, and gynaecology, occupying every afternoon and some mornings, will start on November 15th, and will include lectures and clinical demonstrations on diseases of the nervous system, feeding of infants, congenital heart disease, diseases of the blood, kidneys, thyroid, joints, stomach, and intestines, with gynaecological diagnosis, consideration of the commoner gynaecological affections, ophthalmia neonatorum, and skin diseases, and modern methods of laboratory diagnosis. A course at the St. John's Hospital for Diseases of the Skin, from November 15th to December 11th, will include daily instruction in the out-patient department, and lectures on Tuesdays and Thursdays. The West End Hospital for Nervous Diseases, from November 22nd to December 18th, will hold lecture-demonstrations daily at 5 p.m. At St. Mark's Hospital, from November 22nd to 27th, there will be a course of operations, demonstrations, and lectures, and at the London Temperance Hospital, from November 29th to December 11th, a course in medicine and surgery in the late afternoons. Copies of all syllabuses, the general course programme, and the *Post-Graduate Medical Journal* may be obtained from the Secretary of the Fellowship, 1, Wimpole Street, W.1.

THE People's League of Health has arranged a series of eight lectures on "Diet: What we should eat and why," to be delivered in the lecture room of the Medical Society of London, 11, Chandos Street, Cavendish Square, W.1, commencing on Wednesday, November 3rd, at 6 p.m. The lecturers include Professors Leonard Hill, Winifred Cullis, W. E. Dixon, and Hugh Maclean, and Dr. Harry Campbell. The fee for the series will be 8s. The syllabus may be obtained from Miss Olga Nethersole, 12, Stratford Place, W.1.

A FURTHER extraordinary general meeting of the Medical Sickness, Annuity, and Life Assurance Society will be held at the offices of the company, Lincoln House, 300, High Holborn, W.C., on Monday, November 1st, at 4 p.m., for the confirmation or otherwise of the resolution approving alterations in the articles of association adopted at the meeting on October 11th.

THE Norman Lockyer lecture for 1926 will be given in the Goldsmiths' Hall on Tuesday, November 23rd next, at 4 p.m., by Mr. J. S. Huxley, Professor of Zoology and Animal Biology at King's College. Its subject will be biology and human life. Tickets can be obtained from the Secretary, British Science Guild, 6, John Street, Adelphi, London, W.C.2.

THE London Clinic of Psycho-Analysis has recently been opened for the out-patient treatment of cases found suitable for this form of therapy. Its purpose is to place a method of treatment that is lengthy and therefore usually expensive within the reach of those who cannot afford the usual or indeed any fees, and to provide opportunity for the training, under supervision, of medical students and practitioners who desire to specialize in this branch of work. The staff consists of the following honorary physicians: Drs. Ernest Jones (honorary director), Douglas Bryan, E. M. Cole, M. D. Eder, Edw. Glover, M. B. Herford, W. Inman, Sylvia M. Payne, R. M. Riggall, W. H. B. Stoddart, and John Rickman (honorary secretary). The address of the clinic is 36, Gloucester Place, W.1.

THE British Social Hygiene Council has arranged a course of lectures to teachers and those concerned with education, to be held at the College of Nursing, Henrietta Street, Cavendish Square, W.1, at 5.30 p.m. Mr. D. Ward Cutler will open the course on November 4th with a lecture on the contribution of biology to social hygiene. Dr. Feldman will describe the contribution of physiology to social hygiene on November 11th. Dr. J. A. Hadfield will discuss the contribution of psychology to social hygiene on November 18th. Dr. Mary Buchan Douie will discuss adolescent and social hygiene from the standpoint of the home on November 25th, and on December 2nd Professor Winifred Cullis will lecture on adolescent and social hygiene from the standpoint of the school. Free tickets can be obtained from the London secretary of the Council, Carteret House, Carteret Street, S.W.1.

A NATIONAL conference on milk in relation to public health will be held in the King George's Hall, Caroline Street, Great Russell Street, W.C.1, on Tuesday, November 16th. At the morning session reports will be received from public authorities on the present conditions of the milk supply, Dr. Harriette Chick will read a paper on milk in relation to public health, and Dr. W. G. Savage will open the discussion. The afternoon session will open with remarks by the Minister of Health, and consideration will be given to suggestions received by the conference committee as to steps to be taken by the public, public authorities, and the Government for the improvement of the milk supply. A general discussion will be opened by Professor H. R. Kenwood.

A QUARTERLY meeting of the Royal Medico-Psychological Association will be held on November 16th at the Horton Mental Hospital, Epsom, when it will be proposed to form a special committee on research and clinical psychiatry as a preliminary to the appointment, at the next annual meeting, of a standing research and clinical committee to consider the most profitable lines on which the matter can be pursued. It will be proposed also to ask each division to appoint a clinical committee to organize regular meetings devoted solely to the clinical aspects of psychological medicine on such lines as will encourage the attendance primarily of assistant medical officers. In the afternoon a paper and clinic on chronic epidemic encephalitis will be given by Dr. P. K. McCowan and Dr. J. S. Harris, at West Park Mental Hospital, Epsom, and a visit will be paid to the Manor Institution for Mental Defectives. On the previous day (Monday, November 15th), at 4 p.m., an address will be given at the British Medical Association House, Tavistock Square, W.C., by Dr. Alfred Adler, of Vienna, on the cause and prevention of neurosis.

At the annual dinner of the Chelsea Clinical Society on October 26th, the president, Dr. Ernest Charles Young, took the chair, and a record attendance of members was present. The toast of "The Visitors" was proposed by Mr. Ivor Back, who coupled with the toast the names of Lord Carson, the Dean of St. Paul's, and Sir Arthur Conan Doyle. Lord Carson, in replying, spoke of his appreciation of the personal help he had received from doctors during his life, and admitted that he thought they appeared to greater advantage in the consulting room and at the bedside than in courts of law. The Dean of St. Paul's confessed to a strong sympathy with doctors, of whose services, however, he was glad that he had not had to take advantage very often. He contributed two humorous anecdotes to the gaiety of the evening. Sir Arthur Conan Doyle remarked that, although he felt somewhat of a traitor to the medical profession, having deserted it after comparatively short service, yet his professional life, though not very long, had certainly been broad, and perhaps deep. He thought he was the only representative present of the old unqualified assistant,

on whose character and activities he touched lightly and tactfully. His medical work had also been conducted in ships, while he had once occupied a consulting room and a waiting room in Wimpole Street, both of which, however, he had found to come under the latter title. The remaining boasts were the Chelsea Clinical Society; the Allied Societies, with special reference to the Hunterian Society, the dinner meetings of which had been copied by the Chelsea Clinical Society; and the health of the president, who said that the society aimed at being of particular value to general practitioners. A gratifying feature was the excellent attendance at its meetings during the past year, while the membership had also reached its highest point so far. The prospects for the future were very good.

At the third Pan-Pacific Scientific Congress, to be held at Tokyo from October 30th to November 11th, the following subjects will be discussed in the medical section: (1) the prevalence, prophylaxis, and treatment of diseases on the Pacific Coasts; (2) the prevalence, symptomatology, prevention, and treatment of dysentery, ankylostomiasis, and Japanese schisto-omiasis; (3) the climate, feeding, clothing, and power of resistance of the inhabitants of different parts of the South Sea Coast.

DR. HAMEL, President of the German Health Department, has been elected member of the Commission for Combating Tuberculosis appointed by the Committee of Hygiene of the League of Nations.

THE late Mrs. Margaret H. Hamilton-Fallowes, who died in August last leaving estate amounting to nearly £2,000,000, has bequeathed £1,500 to the Boscombe and West Hants Hospital to endow a bed in her memory, and £1,000 each to the Royal Waterloo Hospital for Children and Women, the Royal Surrey County Hospital, Guildford, and the Royal Ophthalmic Hospital.

## Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to **THE EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.**

**ORIGINAL ARTICLES** and **LETTERS** forwarded for publication are understood to be offered to the **BRITISH MEDICAL JOURNAL** alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring **REPRINTS** of their articles published in the **BRITISH MEDICAL JOURNAL** must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs.

All communications with reference to **ADVERTISEMENTS**, as well as orders for copies of the **JOURNAL**, should be addressed to the Financial Secretary and Business Manager.

The **TELEPHONE NUMBERS** of the British Medical Association and the **BRITISH MEDICAL JOURNAL** are **MUSEUM 9861, 9862, 9863, and 9864** (internal exchange, four lines).

The **TELEGRAPHIC ADDRESSES** are:

**EDITOR OF THE BRITISH MEDICAL JOURNAL, Aitiology Westcent, London.**

**FINANCIAL SECRETARY AND BUSINESS MANAGER** (Advertisements, etc.), *Articulate Westcent, London.*

**MEDICAL SECRETARY, Mediscera Westcent, London.**

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Bacillus, Dublin*; telephone: 4737 Dublin), and of the Scottish Office, 6, Drumsheugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone: 4351 Central).

## QUERIES AND ANSWERS.

### RECURRENT MONSTERS.

"**P.L.V.I.S.**" asks for suggestions for the treatment of the following case: A woman, married three years, now aged 29, has twice become pregnant. The pregnancies terminated at seven and six and a half months respectively with hydramnios, anencephaly, spina bifida. Her husband is about 40. There is no suspicion of venereal trouble on either side. This woman suffered from spinal scoliosis as a girl. There is still some deformity and apparent tilting of the pelvis.

### RECURRENT BOILS.

DR. D. MCASKIE (Southsea) writes: "I 'W. L.-C.' (Torquay) (*JOURNAL*, October 16th, p. 717) will, as soon as he sees a boil appearing, apply 83 plaster-mull, the boils will be at once aborted.

**SERGEON-LIEUTENANT L. P. SPERO, R.N.**, states that he has found the following line of treatment of recurrent boils very satisfactory: (1) The urine is often strongly acid; if so, it should be rendered alkaline with potassium citrate and sodium bicarbonate (large doses are necessary sometimes), and then endeavour to maintain the urine neutral, or, at all events, to diminish the

acidity as much as possible. (I am presuming the question of diet has been tackled.) (2) Take a piece of lint larger than the boil and cut a very small hole in the centre. Smear ung. hydrarg. ammon. (3) on the lint and apply to the boil and surrounding area, so that the aperture is over the centre or that part which is most likely to "point"; now soak a piece of gauze in 1 in 20 carbolic, squeeze out and place over the aperture, covering all with a thick pad of wool and bandage. This simple dressing is most effective and should be done once or twice a day. It is said, I believe, that hot fomentations tend to reinfect. I have had far better results since giving them up entirely.

### WARTS AND EGGS.

DR. C. LUTHER BATTESON (Watford) writes: In answer to Dr. Leonard Williams's inquiry in the *JOURNAL* of October 23rd (p. 763), it used to be a common superstition in my young days in the East End of London that drinking water in which eggs had been boiled would cause warts. I have known people make tea or cocoa with the water in which eggs had just been boiled, but have no evidence that warts were ever caused thereby.

### INCOME TAX.

#### Assessment.

"J. W. G." refers to the reply to "A. G." in our issue of October 2nd, 1926, and asks for a fuller explanation of the distinction referred to therein.

"\*." The case of *Tennant v. Smith* (*Appeal Cases*, 1892, p. 150) decided that if the holder of an office receives a salary and, in addition, an advantage—such as free residence—of which he is obliged to avail himself, and which he cannot transfer to others for profit to himself, then he is assessable in respect of his salary only. In the later case, *Cordy v. Gordon* (41 *Times Law Reports*, p. 401), Rowlatt, J., drew a distinction between the above facts and the case where a person is paid a salary and out of that salary has to pay a counter amount to secure himself some necessities which his employers think he ought to have in a certain form; in such a case the gross salary, and not the excess over the counter-charges, is held to be assessable.

## LETTERS, NOTES, ETC.

### POTASSIUM CHLORATE IN CONGENITAL GOITRE.

DR. R. VERNON BAILEY (Manchester) writes with reference to Dr. R. K. White's article on potassium chlorate and congenital goitre (*JOURNAL*, August 14th, p. 332) to point out that Professor W. E. Fothergill of Manchester published the description of a similar case in the *BRITISH MEDICAL JOURNAL*, 1903, i, p. 847, and also in the *Journal of Obstetrics and Gynaecology* in January, 1904, under the title of "Maternal eclampsia: hypertrophy of foetal thyroid."

### TREATMENT OF NEOPLASMS.

MR. G. S. THOMPSON, F.R.C.S. (Sydney, N.S.W.) writes: In view of the recent articles and work on the treatment of malignant growths and the claims to priority therein, I wish to call attention to the special (prize) article written by me in 1909 from Kimberley, South Africa, and published in the *Hospital* (London) on June 4th, 1910 (pp. 283-84), in which I elaborated my theory and practice of the treatment of neoplasms by inoculation of growth substances to produce active and passive cure, either by inoculating the patient with growth substance (active immunization) or immunized serum (passive immunity), etc.

### ST. KILDA.

DR. ROBERT GORDON MACDONALD (Dunedin, New Zealand), who tells us that it is now some fifty years since he joined the British Medical Association, sends the following note on the article on St. Kilda, published on July 10th:

I visited St. Kilda many years ago when on a visit to the Old Country, and was much interested in the place and its people. The "shore cough" you refer to was, and probably still is, quite common throughout the more remote Highlands, both on the islands and mainland. The people spoke of it as "Cnatana na gall," or Saxon's cold. On settling in Dunedin over forty years ago I thought I would never again hear of "Cnatana na gall," but it is quite common here. When shepherds from far inland sheep stations visit town in winter, which is their off season, they invariably develop "Cnatana na gall" on the second or third day of their visit. The Saxon shepherds call it "flu," while the Highland shepherds still call it "Cnatana na gall." All these people live in a germ-free atmosphere at home, but when they meet strangers or visit towns they invariably develop feverish symptoms with cough. Though St. Kilda and Dunedin are about the extreme ends of the British Empire, they are one in "Cnatana na gall."

### VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 37, 38, 39, 42, and 43 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 40 and 41.

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 203.

## Thomas Vicary Lecture

ON

## THE SIGNIFICANCE OF ANATOMY.

DELIVERED BEFORE THE ROYAL COLLEGE OF SURGEONS  
OF ENGLAND

BY

G. ELLIOT SMITH, M.D., D.Sc., F.R.S.,

PROFESSOR OF ANATOMY, UNIVERSITY COLLEGE, UNIVERSITY OF LONDON.

MR. PRESIDENT AND FELLOWS.—In the first place I must express to you, Sir, my appreciation of the unexpected distinction of being invited by your predecessor, Sir John Bland-Sutton, to deliver this address.

It may seem strange that in this museum where the Hunterian Collection is housed I should discuss such a subject as the significance of anatomy, the scientific and practical value of which as the essential foundation of surgery John Hunter has surely established once and for all. But no one who is familiar with the attitude towards morphology which is widespread at the present time can doubt that there is need for an appreciation of the part the study of anatomy has played in the history not only of biology and medicine but also of civilization as a whole, and the even greater services it still remains for the morphologist to achieve.

At the present time it is not only the physiologists and clinicians who fail to realize the importance of morphology, but also some anatomists and even more biologists bow the knee to the strange fashion of depreciation. In some famous medical schools it is considered almost an offence on the part of an anatomist or biologist to devote himself to the essential business of his subject, and work at real anatomy. The interest and importance of experimental embryology and the fascination of this method of interrogating the processes of nature everyone will readily admit. But even the fullest recognition of the value of such work and of the brilliance of its pioneers does not lend any sort of justification for the strange assumption that anatomists who devote their attention to other no less important parts of their subject are wasting their time in obsolete diversions. The situation has been so accurately diagnosed by Professor H. S. Jennings of the Johns Hopkins University that I make no apology for quoting him. Referring (*Science*, July 30th, 1926, p. 98) to anatomy as "the physics of organism," he said:

"It requires separate consideration, both because of its extreme importance for zoological experiment, and because it was minimized, nay, despised and rejected of the physiological impulse in zoology. This is the role of physical arrangements of material in organisms; gross physical arrangements as well as minutest ones; what is variously called organization or structure. Structure had become the object of one of those epidemic phobias that beset scientific men as they do other men. In the days before experimentation zoologists had given a romantic and mystical turn to the phenomena of structure in organisms; they built upon it a great edifice which was called morphology. They discovered in organic structure plans, styles, comparable to the diverse styles of architecture—to Gothic, Romanesque, Classical, and the rest. But the physiologists said: This may be pretty, but is it Science? It is not. Out with it. We shall have nothing to do with morphology; it is fantastical. And throwing away the baby with the bath water, they largely rejected also the role of structural arrangements, even in experimentation. This it was that led to most of the adventures or misadventures of the sort I have recounted, in the progress of experimental zoology. It is important that this phobia should no longer dominate our work. Consider for a few moments the role of arrangements or organization in experimental work, and the consequences of its neglect.

"Structural arrangement, organization, is of course physics; we find it playing a very great role in physics as that science advances. The properties of atoms depend upon the arrangement of electrons; of molecules on the arrangement of atoms; of crystals on the arrangement of molecules. In organisms there is a great extension of this. They are bodies in which the arrangements have become complex and differentiated, and have passed into the grosser, the visible features as well as in the finer details. They are bodies in which there is an almost infinite variety of these arrangements, as we pass from species to species. They are systems of structures. In consequence, their properties and the way they respond to experiments, depend largely on these systems."

This so admirably explains the real significance of morphology as the foundation of all science, physical as well as biological, that it is hardly necessary for me to add to it. It also emphasizes the fact that when dissociated from morphology so many lines of experimental research soon become exhausted.

The disparagement of anatomy extends also to morbid anatomy, and at the present time in many schools, with a few conspicuous exceptions, medicine and surgery are suffering from the neglect of adequate morphological inquiry into the reasons for diagnostic and therapeutic failures.

The eponymous label attached to this lectureship is not without significance. Thomas Vicary was the Court surgeon of Tudor kings and queens, and he left behind him an obsolete treatise on scholastic anatomy, based upon the writings of Lanfranchi and Mondeville in the fourteenth century, which completely ignored the revolution that had been effected in the whole outlook and discipline of anatomy by Vesalius twenty years before Vicary's death. Like Thomas Vicary, the anatomist at the present day has retained in his teaching an undue amount of mediaeval method and material that has no justification either on the ground of its practical or scientific value. In paying respect to these antiquated conventions—what earlier bookmen wrote rather than what the body itself reveals—he has neglected the great opportunity of bringing the subject of anatomy into closer correlation with the needs of the times. The possibilities for great achievements in anatomy were never so great as they are to-day; and the need for men who will devote their whole time and energies to the exploitation of these rich veins of ore was never so urgent as it is now in England. It was a great step forward when, a generation ago, men were appointed to devote their whole time to research and teaching in anatomy. The problems to be solved are so complex, and the technique of inquiry so exacting, that those who work at the subject must be wholly absorbed in it.

It will help us to realize what anatomy has done for mankind and civilization if we glance at certain aspects of its history. So far as the development of a systematic study of the human body is concerned, the Ptolemaic school at Alexandria, founded by the disciples of Aristotle three centuries before Christ, represents the beginning of the story. In the museum, which was the essential achievement of that school, the discipline of true science was developed and organized. This Egyptian town gave the world its greatest heritage—namely, the scientific method. This decisive advance in the history of civilization extended to all sciences. It was the triumph of the inductive method based upon observation and the formulation of laws to give expression to the observed facts as generalizations. Experimentation was the complement of the inductive method, but not the real foundation of it, for without morphology experimentation would be quite inconclusive and frivolous.

In studying the development of the scientific school at Alexandria it is important to remember that the anatomical researches of Herophilus and Erasistratus played a very important part, not simply in establishing the importance of observation in anatomy itself, but in the demonstration of method for all the sciences. As Galen, a student of the Alexandrian school, pointed out five centuries later, the study of the phenomena of life is based upon the solid foundation of anatomical observation, experiment, and clinical observation. Until the anatomists had begun their work the profession of medicine lacked any real discipline and professional standard. Galen attributed to an ignorance of anatomy on the part of medical men the lack of success in the treatment they often administered.

The special force of these observations is revealed more clearly if we push back the inquiry to the dawn of civilization, more than thirty centuries before Aristotle. Then it becomes clear that the study of mankind (and in particular the phenomena of life and death) was indeed the sole aim of all science and art.

The farther back we go in the history of civilization the more definitely and exclusively anthropocentric all inquiries into natural phenomena become. There is no innate curiosity in mankind to study the forces of nature; but such things as seemed directly to affect his own welfare appealed to man's interests. Man did not at first study physics, astronomy, zoology, and botany simply for the intellectual joy of discovery, but so as directly to benefit himself other than by a reputation for wisdom. In particular attention was paid to the problems of life and death, the solution of which might enable man to safeguard his own existence and avert the risks of death.

For example, celestial phenomena at first interested man solely because the moon seemed to control the physiological periodicity of women and the life-giving functions. The sky, therefore, was believed to regulate and measure the duration of life, and was studied for the purpose of controlling human destiny—a sort of life insurance of the individual who made the inquiries. It can be shown that in a similar way all man's early nature studies were self-centred, and in the last resort were related to the expressions of life in his own body—the heart, liver, kidneys, the breath, the blood, the moisture, and the odour of life—the safeguarding of which was the underlying motive of all early speculation and belief. Several millennia before man systematically studied anatomy he was building up the fabric of civilization under the influence of doctrines based upon his ideas of the functions of his heart and blood, his breath and moisture, the placenta and the "life-substance." It would, in fact, not be an exaggeration to claim that civilization was evolved out of man's endeavours to understand the constitution of his own body and to preserve the life that animated it.

All learning was at first focused on the preservation of life. As the Greeks expressed it many centuries later, the healer was a naturalist (physician, from *physis*=nature)—one who studies the forces of nature to safeguard life. Throughout the ages the essential doctrines of philosophy centred around the anatomical facts of the anatomy of the brain and heart, as the means of interpreting thought and behaviour.

But having thus referred to the fundamental significance of anatomical studies in the history of civilization, it will now be more illuminating to cite certain illustrations that have some direct bearing on medicine.

#### WILLIAM HARVEY AS AN ANATOMIST.

In his Harveian Oration a fortnight ago the President of the Royal College of Physicians (Sir John Rose Bradford) gave an eloquent exposition of the significance of the experimental method and of the debt of medicine to Harvey for having introduced it. Thanks largely to the work of Harvey, to quote Sir John's conclusion, we may claim that medicine has a scientific status as a branch of natural knowledge.

In this connexion, however, we should not overlook the fact that Harvey himself called his magnum opus *An anatomical dissertation on the movement of the heart and blood in animals*, and that he was an anatomist, a pupil of Fabricius of Aquapendente, under whom he worked for five years at Padua, when he was demonstrating the existence of valves in the veins. Harvey used his master's picture of these valves to illustrate his own book; and it is clear from his writings that this anatomical fact formed the solid ground upon which was based the great achievement that at the beginning of the seventeenth century transformed the whole scientific outlook on the human body. On the other hand, Sir Charles Sherrington has summed up the experimental investigations of a generation on reflex action in terms of structure.

The state of anatomy in England at the time when Harvey introduced into it the new life of the scientific method is revealed in the fact that Vicary's mediaeval nonsense was still in circulation as a textbook of anatomy at the time when Harvey brought back from Padua the methods of comparative anatomy Fabricius was inculcating. Harvey was none the less an anatomist because he resorted to experiment to test the meaning of the arrangements revealed in the dissection of the body, as every anatomist should in order to interpret anatomical facts. The experimental degenerations in the nervous system, for example, are devices for discovering facts of structure.

#### WILLIAM SHARPEY.

Another British anatomist, who like Harvey was a student of the Paduan school, invented the modern methods of practical physiology at University College. William Sharpey's disciples, Sir Michael Foster, Sir J. Burdon-Sanderson, Dr. W. H. Gaskell, and Sir Edward Sharpey-Schafer, carried their master's methods and his inspiration into other British universities. But, unfortunately for anatomy, these anatomically trained physiologists insisted on retaining microscopic anatomy as part

of their subject, to the grave injury of anatomy in this country. It is worthy of note that until the time of Sharpey there was in England no separation between anatomy and physiology; and it is a consideration of fundamental importance to recognize that each of them should be free to employ any technical methods that promote its particular aims. For anatomy is not simply descriptive: it aims at understanding and interpreting the meaning of structure, and experiment is one of the necessary procedures for elucidating structure. In the school where Sharpey accomplished his great pioneer work efforts are being made to retrieve the disaster he unwittingly inflicted upon his subject. By bringing the two departments into close contact as a single unit, and by integrating the two subjects into one discipline, it is hoped to break down the artificial barriers between the investigators of structure and function.

#### JOHN HUNTER.

If Harvey laid the foundation of a real science of medicine, John Hunter can with equal truth be said to have accomplished a like service for surgery. His principles were established on the basis of a wide comparative study of anatomy and the phenomena of growth. By investigating the means adopted by Nature for dealing with the infinite variety of problems that arise in the animal economy, to use a favourite word of his, Hunter discovered methods to imitate in surgical procedure. He raised surgery from the empiricism of the barbers to become a craft inspired by the methods of true science and a technical skill controlled by reason and understanding.

The late Mr. Stephen Paget refers to the work of William and John Hunter on the lymphatic system as a new truth of vast importance, second only to Harvey's discovery of the circulation of the blood; and in estimating its significance he uses the words so many writers have applied to Harvey's achievement: "it changed the whole character of medical science and practice." That the lacteals, which carry food products into the blood, were absorbent vessels men knew already, but they had not realized that the whole body, every organ and tissue of it, is penetrated and drained by a special system of vessels to bring the fluids in the tissues back into the blood stream. It is not necessary for me to say anything to impress upon this audience the importance of the lymphatic system in surgery and the value of the pioneer work of the Hunter brothers. A vast amount of detailed work on the lymphatic vessels and glands has been accomplished in recent years, and valuable light has been shed, especially by our American colleagues, upon their developmental history. But the satisfactory solution of the controversies that have arisen as to the interpretation of the meaning of these observations will not be attained until we return to comparative methods and study the phylogeny rather than the mere ontogeny of the system.

The brilliant research on the lymphatic system of *Lophius* that has recently been accomplished in this museum by the physiological curator, Mr. Richard H. Burne, is an encouraging sign that this great work is being carried on in its appropriate setting.

#### CHARLES DARWIN.

If Harvey introduced a new era in medicine and Hunter in surgery, Charles Darwin gave the whole world of learning a new outlook.

The recognition of the reality of evolution effected a revolution, not simply in biology, but in every field of intellectual work. Although Darwin's work was inspired primarily by what we now call nature studies, it is clear that the foundation of the argument, without which he would not have been able to convert people to accept his views, was represented by the facts of comparative anatomy and embryology. He himself says in the *Origin of Species* that morphology is the soul of natural history.

Darwin's achievement gave a new orientation and a new meaning to morphology. What is not generally recognized by physiologists at the present time is the vast scope of evolution and the significance of processes that took many millions of years to effect. They do not seem to appreciate that only an altogether insignificant fraction of the great natural processes is susceptible of experimental

inquiry. When they ask what use can be assigned, say, to the morphology of the lizard's chondrocranium, they thereby show a failure to appreciate that the great story of evolution is based upon the linking-up of the facts of morphology and palaeontology. No full understanding of the behaviour of man or any experimental animal can ever be attained without a knowledge of his or its origin and evolution.

#### THE CELL THEORY.

What Professor E. B. Wilson calls a milestone of modern scientific progress—the cell theory enunciated by Scheiden and Schwann in 1838-39—stands forth as one of the greatest achievements in biology, which marked the beginning of a new era in knowledge and its application in practice. Goodsir, Virchow, and their successors used this conception for the analysis of the structure of organisms, and in doing so opened far-reaching vistas of progress in every department of biology and medicine. In more recent times the evidence afforded by the behaviour of chromosomes afforded anatomical corroboration of the results of experimental breeding, and compelled even the geneticists to admit that morphology had its uses.

#### THE PRESENT POSITION OF ANATOMY.

Even if anatomy had achieved nothing more than make vital and essential contributions to the great revolutions in thought effected by William Harvey, John Hunter, William Sharpey, Rudolf Virchow, and Charles Darwin, its place in the forefront of progress would be established. But its claims are much wider than that. Its influence was in fact universally felt in the advance of civilization. It is not, however, the place of anatomy in history with which I am chiefly concerned to-day. It is rather its present position and future development that I want to discuss.

In your museum the word "physiology" is, significantly enough, used to connote comparative anatomy. This uncommon usage expresses an important truth. For no method more clearly reveals the functions of structures than the correlation of their varying size and structure in animals of differing capabilities.

In his comparative study of the heart, and in particular of the bulbus cordis, the present conservator of the museum has shown, perhaps more clearly than in any other of his numerous works, that the spirit of John Hunter is still alive here. For the use of comparative anatomy, in conjunction with the study of the functional meaning of the varying arrangements, to illuminate the normal morphology and pathological states of the heart would have delighted the founder of the museum. Sir Arthur Keith's greatest service to science, however, has been his persistence in keeping constantly before the anatomist the urgent need for the study of function as an essential part of the interpretation of structure. From its foundation the principle has been emphasized in your museum. The use of the term "physiological series" for the collection of comparative anatomical preparations is a happy illustration of the real spirit of Hunter's work.

Take, for example, the case of the cerebellum, which I discussed in the Arris and Gale Lectures in this room six years ago. Some physiologists (for example, Professor Magnus in his Croonian Lecture to the Royal Society this year) are now proclaiming that their experiments do not reveal any functions for the cerebellum; but anyone who walks through the gallery of this museum, where the wonderful collection of vertebrate brains is exhibited, can see for himself that Nature's great experiments in modes of posture and locomotion have left their impress so clearly in the cerebellum that he who runs may read. So also in the morphology of the brain as a whole, the varying sizes and histological structure of its parts express the habits and capabilities of animals and reveal the broad lines of their functions.

In his great treatise *The Integrative Action of the Nervous System*, which opened a new era in the interpretation of the brain's meaning, Sir Charles Sherrington calls the cerebrum "the ganglion of the distance-receptors," by which are initiated and guided long series of reactions of the animal as a whole. Unfortunately he did not avail himself of the facts of comparative anatomy to elucidate and reap the full harvest of his illuminating idea. Here again it requires no difficult technical procedure or abstruse

knowledge to discover facts of fundamental importance, which have escaped those who neglect to give due consideration to comparative anatomy. It is only necessary to look at a comparative collection of brains such as this museum contains to see at a glance that the most primitive type of cerebrum is not equally the ganglion of all the distance-receptors, but predominantly of the one concerned with smell. The part of the brain that eventually became the organ of mind is primarily a receptive centre for olfactory impressions, and the instrument whereby such experience can influence behaviour. The whole arrangement of the brain is dominated by this fact, which is fully borne out by experiments on the dog-fish such as those of Professor Parker of Harvard University.

Considerations of structure cannot be ignored with impunity by those who aim at understanding function. After all, the aim of experiment is to interpret the working of an instrument, and the mode of construction of that instrument cannot be neglected. It is not, however, morphology alone that is essential, but also considerations of phylogeny, the relative place in nature and affinities of the experimental animal, the appreciation of which is based upon morphology. In all investigations considerations of evolution are matters of fundamental importance, and are especially significant in the case of the nervous system, which undergoes profound changes in the course of its history. In such researches as those now being carried on by Professor Magnus and his collaborators the differences of behaviour in various grades of animals are being forced upon their attention. But the full fruits of much patient work are being lost by many physiologists from their neglect of the phylogenetic factor.

How fruitful researches can become when due importance is given to the facts of evolution is revealed in the splendid experimental and clinical researches of Professor Brouwer of Amsterdam. By arranging the experimental animals in an orderly series he has been able to demonstrate the progressive changes that occur in the lateral geniculate bodies, the oculomotor nuclei, and the cerebral cortex in a series of vertebrates, and has shed a brilliant light upon a series of problems of fundamental importance to the morphologist and clinician. In particular, his work illuminates the process of evolution of the brain that ultimately brought about the emergence of man's high intelligence. Dr. Brouwer's researches have given the lead in this country to Dr. H. H. Woollard and Mr. W. E. LeGros Clark to work the rich vein of ore opened up by his genius.

#### THE NEW OUTLOOK IN ANATOMY.

As knowledge advances in physiology, pharmacology, biochemistry, and clinical medicine and surgery a host of new problems arise, for the solution of which anatomy provides in many cases the field of research, and in all cases the coping-stone of objective demonstration, and becomes the last court of appeal for its validity—the translation of elusive modes of reaction into the concrete terms of structure.

Experimental physiology aims at explaining the behaviour of living organisms and tissues, and if it is successful its results must be expressed in terms of the constitution of the organism and its parts. Morphology is not only the foundation of experimental research—the territory in which the work is done and the study of the physical properties of the material investigated—but it also affords the ultimate test of the significance and validity of the results attained. Hence both kinds of investigation are essential and complementary the one to the other. The morphologist and the physiologist should work in close co-operation the one with the other, and the clinician has opportunities for applying their results and making fresh observations suggesting new problems for the morphologist to investigate. How fruitful this co-operation of workers in the three fields can be is shown by recent research in neurology, by such bridge-builders as the Dutch investigators Magnus and Brouwer, who in different domains of neurology have revealed the importance of the combination of morphological, experimental, and clinical methods in dealing with complex problems.

The results of a great deal of experimental and clinical work are being interpreted to-day in defiance of the clear

Facts of structure. The recognition of the significance of morphology is of vital importance as a preventive of such errors. It can also be shown that a lack of anatomical knowledge at certain epochs in the history of civilization was responsible for hampering progress. In 1674 Malebranche (*Recherche de la verité*) expressed his belief<sup>2</sup> in the existence of vasomotor nerves ("Nerfs qui environnent les artères pour fermer, par leur contraction, le passage au sang qui montre vers le cerveau, et l'ouvrir par leur relâchement à celui qui se répond dans toutes les autres parties du corps"), but he lived two centuries before men had sufficient knowledge of bodily structure to appreciate all that was involved in this precocious intuition of genius.

Because anatomy had not prepared the way, for instance, the understanding of the injuries that produce aphasia had to wait for three centuries. In the year 1558 Nicholas Massa published an account of a case of traumatic aphasia, which disappeared after operation. The patient received a blow from a halberd that perforated the base of the skull and penetrated the meninges and brain, into which a fragment of bone was driven. He makes the comment, which in the mouth of a surgeon has a very modern and familiar ring about it, that the physicians had not noticed the depressed bone. Massa assumed that the loss of voice might be due to the pressure on the brain of the piece of bone he had detected. Hence, in the presence of the physicians and other onlookers, he proceeded to remove it. To their intense astonishment the patient at once recovered his speech.\*

It was not until the beginning of the nineteenth century that, as the result of anatomical observations, Dr. Joseph Gall was able finally to demolish the old theory of animal spirits, which had prevented a proper understanding of the nature of the problem. Then the way was prepared for the admission of the reality of cerebral localization. In a work published in 1818 Gall recorded a case of traumatic aphasia such as Massa had seen in 1558—an officer who received a sword thrust just above the left eye and lost "the memory for words." But it took more than another half-century before physiologists and clinicians were willing to admit the reality of localization, and then only when the genius of Hughlings Jackson and Broca and the experiments of Fritsch and Hitzig, Ferrier, and others had given the observations an anatomical setting by assigning to definite areas of the cortex the control of certain movements. The history of these fifty years is told in full by Dr. Henry Head in his great treatise on *Aphasia and Other Disorders of Speech* (1926).

With reference to the question of cerebral localization, it will be common knowledge that the histological investigations of Dr. Bevan Lewis from 1869 onwards established the fact of anatomical localization. Yet Lewis's important work was brushed aside because the precise results obtained by him seemed to come into conflict with those obtained by experimental investigations.

The difference in structure between the pre- and post-central convolutions of the brain was completely overridden by the fact that Sir David Ferrier and others obtained responses to electrical stimulation from both convolutions. It is important to remember that when Sir Charles Sherrington in 1900, using a more exact method of investigation, was able to prove that the post-central convolution was not excitable, the method of histological localization was restored to favour, and the work which Dr. Bevan Lewis had begun more than thirty years previously was taken up with renewed vigour, and yielded some of the most significant additions to our knowledge of cerebral structure, the full extent of which has been impressed upon us recently by the great treatise by Professors Economo and Koskinas.

#### THE SYMPATHETIC NERVOUS SYSTEM.

The new chapter in the history of medicine created by the work of Gaskell, Langley, and Anderson on the sympathetic system was based essentially on anatomical investigations. At the present time the question of the practical and clinical applications of this knowledge is the subject

of lively controversy. There are grave differences of opinion in respect of almost every aspect of these problems. But in the long run the issue will be settled by the facts of anatomy. When we know more of the structure of the nerves passing to muscles and their connexions in the central nervous system the decisive evidence for the solution of these difficult problems will have been attained. In respect of this matter the morphological outlook comes into direct conflict with the attitude taken up by many of those who rely solely on experimental evidence. It is generally admitted that muscles have two more or less distinct functions to perform—contraction and maintenance of posture. The brilliant investigations of Sir Charles Sherrington have demonstrated beyond question that posture is automatically regulated by means of proprioceptive reflex arcs. It is also admitted that in invertebrates there are separate and distinct muscles for performing these two functions, even though the movements of the animal are slow and clumsy.

To the morphologist, in whose outlook ideas of evolution loom more largely than they do to the mere experimentalist, it seems in the highest degree improbable that vertebrate animals, in which muscular activity attains a much higher degree of rapidity, skill, and complexity than it does in most invertebrates, should reveal no corresponding differentiation of muscles and nerves for carrying out these two functions. For fifty years it has been known that there is a duality of innervation. We know that there are differences in muscular fibres—the thick and the fine—the relative proportions of which are responsible for the obtrusive differences in colour between red and white muscles. It seems, therefore, if one applies the morphological argument, in the highest degree probable that the greater efficiency of the vertebrate muscle may be due to the fact that the two kinds of muscle fibre, instead of being separate as they are in invertebrates, are intimately blended to form composite muscles.

We know that in the case of the viscera there are two functionally distinct groups of nerve fibres, and it seems again highly improbable that the voluntary muscles, which have automatic functions to perform like those of the involuntary muscles and in addition the highly complex reactions associated with willed movements, should be less well equipped for these more complicated functions than the simpler muscles. It remains for anatomical studies to provide the explanation of the conflicting evidence derived from experiments and surgical operations.

#### SOME PRACTICAL APPLICATIONS.

In spite of the widespread neglect of morbid anatomy, the development of cytology and the recognition of its fundamental importance in the investigation of cancer is bringing an increasing number of pathologists back to morphological studies. An interesting application of such knowledge is now being made in clinical surgery, in which observations in the cytology of cancer (such as were made years ago by Sir G. Lenthal Cheate) are being used by Dr. McCarty in the Mayo Clinic to determine the prognosis in cases of carcinoma.

Some observations that my colleague Dr. H. H. Woollard has been making on the neuro-muscular lesions of so-called beri-beri induced experimentally by depriving rats of certain vitamins suggest that in the last resort the evidence afforded by the structural changes in muscles and nerves cannot be neglected in any estimate of the effects of food deficiency. This impression is even more emphatically confirmed by the observations on bone growth by another of my colleagues, Dr. H. A. Harris. He has been able to demonstrate by anatomical studies that after any diminution of the growth processes of the body (such as normally occur during the week after birth and in certain phases of puberty, as well as in grave illness, or even deprivation of a diabetic patient of his dose of insulin) an opaque line makes its appearance in x-ray photographs of bones. This has been mistaken for and used as a diagnostic sign of healed rickets, and many observers' work has been vitiated by erroneous interpretations of the effects of vitamins, etc., on bone growth. Such results indicate that morphology provides criteria, by which the influence of the various

\* This case of Marcus Goss is reported in Nic. Massæ, *Epistol. medicinal.*, II, 50-51 (Venetia, 1558); and a similar case in Fr. Aræus, *De rectoria eundem ruiturum ratione*, 62-27 (Antwerp, 1574). My attention was called to these surprising records by the reference to them in Jules Soury, *Système nerveux central*, 1899, T. I.

vitamins on growth and metabolism will in the future be tested, as for some years in California Professor Herbert M. Evans has been testing their potency.

The knowledge of the arrangements of the tracts in the spinal cord that has been acquired within recent years seemed at first to have little more than an academic interest, or at most a use in diagnosing lesions beyond the scope of treatment. But in 1911 Dr. Spiller suggested that the knowledge could be put to the humanitarian purpose of relieving the terrible sufferings of patients with inoperable cancer. In the *Archives of Surgery* three months ago Dr. M. M. Peet has described the truly wonderful results obtained by cutting that part of the antero-lateral column of the spinal cord which conveys impulses provocative of pain. Thus the unfortunate victims of incurable disease can get relief from their suffering without resort to drugs. Such a technical procedure has the advantage over section of posterior nerve roots because it does not deprive the parts of all sensation, and the patient is unaware of any abnormal feeling.

During the last ten years thorough investigation of the effects of nerve injuries in soldiers and the correlation of evidence so obtained with the facts of anatomy has enabled Professor Stopford to extend and clarify our knowledge of the arrangement of the sensory nerves and has given the surgeon new and exact methods for the diagnosis and prognosis of nerve lesions.

Only four years ago the pancreas used to be cited as an example of an organ which when diseased could give rise to such profound changes in the whole organism as we know in diabetes without revealing any structural indications of disease. But we now know that this is no longer the case. The morphological changes in the islands are clear enough once one knows where to look for morbid changes.

The anatomical localization of the lesions of encephalitis lethargica and morphological studies to determine the sites of injuries to the mid-brain and hypothalamus that in experiments and clinical cases give rise to definite reactions of body and mind will eventually give us a new insight into the physical factors concerned with personality, and also the neural processes concerned with the manifestations of the common symptoms, such as raising of the body temperature, nausea, etc., in grave constitutional diseases with which every medical practitioner is daily concerned.

These instances chosen at random are enough to indicate that in the near future anatomy promises to become the stepping-stone to a new revelation of knowledge, which will illuminate the whole field of human endeavour.

In this address I have endeavoured to suggest the vastness of the opportunities that now present themselves in anatomy, and how vitally they affect the progress of surgery, not merely the mere craft of operating, but also the wider problems of diagnosis, prognosis, prevention, and treatment. This College has the power actively to promote progress on these lines, which I hope you will permit one who is beyond the pale of your membership to mention. By means of the primary examination for its Fellowship it can insist that the rising generation of British surgeons is inspired with the true spirit of understanding of the human body and is alert and open-eyed to appreciate the great vision that is about to be revealed. Instead of helping the persistence of the medieval conceptions of anatomy, it can encourage the development of an anatomy that deals with really vital problems. The College has in its great museum the most valuable instrument for promoting the study of anatomy on right lines. The growth of the collection started by John Hunter is one of the great scientific achievements of the last century; under the direction of Sir Arthur Keith the opportunities for the comparative study of anatomy have been brought to a higher pitch of efficiency than ever. The College has it in its power to induce the candidates for its Fellowship to avail themselves of this wonderful instrument that is now too much neglected, and in doing so it will enhance the importance of the College itself and raise the standard of the science and practice of surgery.

## SURGICAL TREATMENT.

THE subject of this discussion is so vast that no individual speaker can attempt to deal with more than a small section, and even then anything in the nature of detail is not to be thought of.

In the time at my disposal I propose to consider briefly some of the general principles involved in the surgical treatment of malignant disease of the mouth, fauces, and the oral and laryngeal portions of the pharynx. These will be considered under four heads: (1) selection of cases; (2) preparation for operation; (3) the operation; (4) after-treatment.

## Selection of Cases.

As regards suitability for operation, cases fall naturally into three groups—favourable cases, doubtful cases, and hopeless cases.

The group of really early, favourable cases is a small one—10 per cent. of the total or less—and includes those in which the primary growth only involves a limited area, no enlarged lymphatic glands are palpable, and the general conditions are good. In the majority of such cases operation results in apparent cure, but even here it is easy to be too optimistic—for instance, the smallest epithelioma of the tongue I ever saw led to the death of the patient from secondary deposits within three months.

Doubtful cases constitute the majority—I should say about 50 per cent. of the total. Here it is usually a question of giving the patient a chance, and provided that the growth can be completely removed without too great interference with function, there is a chance of cure, a probability of a considerable respite, and almost a certainty of alleviation, even though the primary growth is extensive and the glands on one side of the neck are definitely invaded. The actual site of the growth is largely immaterial, for if a suitable method of approach is adopted the growth can usually be so completely exposed to view that its removal is comparatively simple. About four in every ten cases I see are obviously hopeless, either on account of the extent of the primary growth, or of the glandular involvement, or both. Even here, however, a purely palliative operation may be indicated—for instance, the removal of a tongue that has been largely converted into a fetid, bleeding ulcer, and is associated with extensive glandular disease, or the destruction of a widespread ulcerating growth by diathermy, will quite often give the patient several comparatively comfortable years.

Perhaps the most difficult decision which has to be made relates to the group of doubtful cases which more nearly approach the hopeless class. I can only suggest that every factor which has a possible bearing on the question must be taken into consideration and carefully weighed in the light of experience. While desiring, on the one hand, to avoid subjecting the patient to a trying ordeal which is foredoomed to failure, yet, on the other hand, it is necessary to be careful not to let slip the chance of a brilliant success.

*Preparation for Operation.*

The principal dangers and complications of these operations are the result of infection of the operation wound or of the lungs. These complications are more prone to occur, and are more serious when they do occur, if the mouth is septic owing to the presence of teeth.

The teeth must therefore claim first attention. Should the patient be already edentulous there can be no doubt that the dangers of the operation and the risk of complications are greatly lessened unless there be some other cause of infection present. If, however, the patient is not already edentulous, should he be always made so? In spite of the strong opinions that have been expressed, I do not think that this question should be considered closed, and I hope that there will be further discussion in regard to it. The removal of a number of teeth from an old patient whose health is already affected by the presence of a malignant growth is admittedly a serious matter. Moreover, the time taken for recovery from the extractions, and for getting the gums soundly healed, will probably be three or four weeks. In the circumstances this loss of time, while rendering the operation safer, may also destroy the chance of cure. Is it justifiable in every case? It is my practice to be guided by circumstances. If the patient has a good set of sound clean teeth I do not advise extraction; if he has a number of obviously septic teeth I usually have them removed. If, however, the teeth are in fairly good condition I trust to careful scaling and cleaning up, with perhaps a few extractions, especially if the patient is old and in poor health.

Oral sepsis may also be maintained by infected tonsils. The danger from these is lessened by painting with 1 in 500 chinolol in glycerin for a few days. During the period before operation the mouth and the primary growth should also be rendered as clean as possible by frequent use of mildly antiseptic mouth-washes and sprays; the general condition is improved by means of rest, fresh air, abundant food of suitable character, and careful regulation of the bowels.

*The Operation.*

The anaesthetic I have used for many years in all major operations upon the nose, mouth, and throat is either administered by intratracheal insufflation. Of the many advantages of this method two call for special mention. The first is that the perils of chloroform, both during and after the operation, are avoided. The second is the elimination of all risk of pulmonary infection from inspiration, at all stages of the operation. This is of particular importance during the removal of the glands, if this is undertaken prior to the removal of the primary growth, and while the preliminary operation for the exposure of the growth is being performed. During these procedures the patient is lying for a considerable time under deep anaesthesia with a foul ulcer somewhere in the neighbourhood of the upper opening of the larynx. This must involve a serious risk of sowing the seeds of an inspiration pneumonia before the main operation is even begun. This risk can only be eliminated either by preliminary laryngotomy or tracheotomy and plugging the pharynx or trachea, or by intratracheal insufflation of ether: the latter is obviously far simpler and safer. There is one objection to the method and that a small one: haemorrhage is rather more free than when chloroform is given through a laryngotomy or tracheotomy tube, and consequently the operation takes rather longer.

With few exceptions the operation upon the primary growth consists of three distinct procedures—namely, the operation of approach by which the growth is exposed to view, the removal of the growth with a sufficient margin of healthy tissue, and the repair of the wound.

In a small group of cases, where the growth is quite small and superficial and can be comfortably reached through the mouth, either with or without division of the cheek, all that is needed is the removal of the growth, with three-quarters of an inch of healthy tissue round it, either by the knife or by diathermy. In the former case the wound must be closed by a number of mattress sutures of catgut bringing broad surfaces into apposition. In all other cases

an operation of approach, carefully planned according to the site of the growth, will be needed.

Without going into the details of these operations some of their main features may be reviewed. It is usually convenient first to clear the corresponding side of the neck of lymphatic glands and vessels. The first incision follows the anterior border of the sterno-mastoid for its whole length; a second passes from the chin to join the first at a right angle. The two skin flaps are then dissected forwards. The deep fascia is divided in front of the sterno-mastoid, as recommended by Mr. Trotter, so that the flap thus formed may later be sutured to the prevertebral fascia in front of the main vessels, which are thus completely shut off from the main wound. The advantages of this step are obvious. All glands are now removed, together with the internal jugular vein if necessary, and the external carotid is tied close to its origin.

The further steps are necessarily dependent upon the site of the growth. If this is oropharyngeal, involving tonsil, fauces, pharynx, or base of the tongue, the mandible must be sawn through in front of the masseter, and the mucous membrane of the mouth and the pharyngeal wall then divided to a sufficient extent and the wound widely retracted, the incisions being so planned as to serve, at any rate in part, for the removal of the growth. If, on the other hand, the growth involves the laryngeal portion of the pharynx the pharyngeal wall will be divided lower down, usually after removal of the great cornu of the hyoid bone and of the greater part of the ala of the thyroid cartilage.

Before opening the pharynx it must be isolated so far as possible from the surrounding tissues by gauze packs in order to minimize the risk of infection of the wound by pharyngeal contents, and after the growth is exposed it also should be further packed off. The next step—removal of the growth—may be effected either by excision or by diathermy. In my opinion the principal advantage of diathermy is that the peripheral coagulation seals off the surrounding tissues. In consequence of this the most serious danger involved in these operations—that of spreading infection—is practically eliminated. The chief disadvantage, on the other hand, appears to me to be the increased danger of pulmonary sepsis resulting from the prolonged local suppuration associated with healing and cicatrization.

So far as I am concerned the question of using excision or diathermy is at the present moment *sub judice*, but, as regards actual practice, if the base of attachment of the growth is small, so that after removal the wound can be securely closed, I prefer excision; if, however, the growth is large and irregular I am inclined to favour diathermy.

At the end of a long operation, and especially if the anaesthetist is not very well pleased with the patient's condition, the last stage of the operation—the closure of the wound—may tend to be rather hurried. It must be remembered, however, that the upshot of the whole operation is dependent in great measure upon the successful closure of the opening into the pharynx, for the infection which results from leakage is always serious and may be fatal. Security against leakage from the pharynx can only be obtained by inserting numerous mattress sutures bringing broad submucous surfaces together, further sutures approximating the muscles and occluding all spaces. Of the superficial wound the part over the sutured pharynx is left widely open and lightly packed, thus making provision for possible leakage. The rest of the wound is sutured, a drain being left in the lower angle.

The removal of the more extensive growths may result in a defect which cannot be completely closed at the time, but will require a plastic operation later. In these cases the mucous membrane should be sutured to the skin edges. This will help to prevent spreading infection and subsequent cicatrization, and will, moreover, greatly simplify subsequent plastic measures.

The removal of a hypopharyngeal growth, either alone or combined with total laryngectomy, will also result in a defect which cannot be closed by direct suture of the pharyngeal wall, but must either be made good by a skin flap, which will need to be provided for by the original

incisions, or, failing this, a cicatricial stricture may be allowed to form. This will require to be kept dilated by a Gluck's tube.

#### *After-Treatment.*

I will consider only one point under this head—that of feeding. This is usually provided for by means of a tube passing either through the mouth or the nose. In either case the tube sets up a varying degree of discomfort and irritation which results in excessive secretion of saliva and perhaps coughing, both of which would be better avoided. This can be done by passing a soft rubber catheter through the wound in the neck into the pharynx in an oblique direction so that the opening in the skin is not opposite to that in the pharynx. Both pharyngeal wall and skin are fixed tightly round the catheter so that it does not tend to slip out and no leakage takes place. Abundant fluid food can be given in this way for as long as is thought desirable without causing the patient any inconvenience, and when the catheter is finally withdrawn, owing to the valvular track, there is no leakage and the opening closes at once. I have adopted this plan for a number of years and have found it a very great advantage.

#### TREATMENT BY X RAYS.

The treatment by x rays of disease occurring in these regions has, up to the present, not been very satisfactory—as is also the case with other methods. The site of the lesion makes it very difficult to evolve a satisfactory technique, while the small area involved, and the number of structures in this small area, give rise to difficulty in accurately restricting the beam of rays to the structures under treatment. For cosmetic purposes it is essential that the skin and subjacent tissues should not be damaged, but the chief difficulty is one of dosage; in such a limited available depth of tissue it is not easy to administer anything like a satisfactory dose without running the risk of damage.

Recently, however, in the case of both radium and x rays, advances of technique have brought the possibility of administering a satisfactory dose perceptibly nearer. With both agents this advance has been made possible by increasing the power of the apparatus. In the case of radium Regaud has shown that large quantities used in a special way, and heavily filtered, will produce results in malignant disease of these regions which show a great improvement on those formerly obtained. Similarly with x rays, higher voltages enable us to apply a greater intensity at the depth, while working at a greater tube distance. Filters on the skin of 2 to 10 cm. of wax aid in the giving of a strong dose in the depth with no risk of skin damage.

Working with x rays on somewhat similar lines as Regaud is doing with radium, we have been able to obtain response of a favourable kind in diseases which up to this time baffled us. On the assumption that an erythema dose or more on the skin is the accurate measure of the dose necessary to induce biological response of a favourable kind, and also assuming that to a similar type of growth situated more deeply in the body a dose of like nature will induce the same change, we were led to experiment with radiations of medium wave-length. We increased the anticathode skin distance to 20 inches, or 50 cm., using a filter of 0.1 mm. of lead with a voltage of 135 kilovolts, 4 amperes, primary current, 4 milliamps. in the secondary; on the skin wax to the depth of 2 to 6 cm. was used according to the type of growth and its depth from the surface. A pastille placed at the half-distance under these conditions required a time exposure of 330 minutes, or 5½ hours.

As a result of these experiments we found that a pastille dose can be given with safety, so far as the skin is concerned, in one sitting, but as a rule only fractions of the dose have been given at short intervals. Various voltages

can be used under the same conditions, and a dose worked out for each. The shorter or more penetrating ray will take a relatively shorter time for the production of the same effect in the deeper structures. Technique of the same order has been extensively used in enlarged cervical glands secondary to malignant disease of the upper air and alimentary tracts, with beneficial results; the glands have slowly diminished in size, while the primary growth has in a number of cases shown improvement.

#### *Accuracy of Diagnosis.*

In the treatment of diseases in these regions an accurate diagnosis is essential. Malignant disease of the upper air passages and alimentary tract is frequently accompanied by secondarily affected glands, and it is often the latter which first call attention to the disease and give rise to distressing symptoms. The distinction has therefore to be made as to whether the glands are primarily affected or are secondary. A careful search for a primary lesion will almost invariably settle the point.

A greater difficulty is to determine the nature of the disease. The chief conditions likely to confuse the diagnosis from malignancy are tuberculosis of the glands, syphilis, and actinomycosis. The differential diagnosis is not always easy. In doubtful cases, when a primary lesion cannot be found, a few x-ray treatments may indicate the nature of the disease. The response generally met with in glandular enlargements is striking—the glands diminish most rapidly in simple inflammatory conditions; in lymphadenoma and lymphosarcoma the response is often nearly as rapid; in tuberculosis the reaction is more difficult to obtain, and a much longer time period must elapse before any diminution in size follows, and in carcinomatous glands the response is very slow indeed—not infrequently there is a total failure to respond.

There is no doubt at all that in comparatively recent times the improvements noticed in cases of the type described as carcinomatous have been more marked and of more frequent occurrence; this has been due to the improvements in the technique of radium and x rays.

The conservative use of x rays in combination with surgical measures is to be commended, and it is urged that in all forms of treatment the earlier the case is treated the more favourable will be the response. In cases where surgical removal is possible, and which are complicated by widespread glandular involvement, pre-operative treatment is advocated; in such cases this will be limited to the glandular enlargements, the primary growth receiving only a fractional dose. In cases where the enlargement of a group of glands is likely to prolong the duration or extend the region of the operation, x rays may be employed to bring the condition within the range of a moderate operation. This has been done in a number of cases. After operation, treatment by x rays should be continued for a period of time commensurate with the gravity of the condition; the x-ray treatment should, however, never be pushed to the extent of depressing the reparative power of the patient; on the contrary, it should be directed to maintaining the natural power of resistance at a high level, or, as often happens, of increasing it when it is below par. By judicious dosage the patient may be tuned up to a considerable degree; this can be proved when repeated blood tests are taken as a check on the treatment.

In inoperable cases, where surgery and other measures are not advisable, x rays may be and are extensively employed, often with no hope of curing the patient, but to alleviate symptoms. In this field x rays have achieved a certain measure of success. The cases quoted serve to indicate the degree of response sometimes met with, and to show that even in the most desperate cases x rays, if used in moderate as distinct from destructive or lethal doses, can give relief, and occasionally much more than relief. Such cases are encouraging also in that they show that there is a definite ground for hope that future advances in technique may yet yield more brilliant results.

The outstanding feature in the improvement of technique has been the recognition of the fact that it is not advisable, and certainly not necessary, to adopt the lethal dose as the unit of effective dosage, but rather to take it as a unit of measurement of a total dose, which can be

spread over several days, weeks, or months, according to the urgency of the symptoms. This has been proved both with x rays and with radium.

### Cases to Illustrate the Differential Diagnosis and Effect of Treatment.

#### CASE I.

A patient was sent for treatment of an enlarged tonsil with greatly enlarged glands in the cervical region posterior to the angle of the lower jaw. When seen in the first instance the skin over the glands was involved, and the condition was diagnosed as epithelioma of that region. The tonsil on the left side was enlarged and reddened. The patient had previously been treated with a mercurial and iodide mixture with no material improvement. Energetic x-ray treatment to the glands resulted in a considerable degree of ulceration and breaking down of the glandular mass. Haemorrhage supervened and the patient was admitted to hospital in a serious condition.

The ulceration had extended down to the bone in the cervical region, and in spite of treatment by various forms of radiation continued to spread. The haemorrhage ceased, and accidentally it was found that he had had a mercurial mixture for a few days while in the ward, after which slight improvement was noticed. A Wassermann reaction gave a strongly positive effect. Thereafter he was put on a thorough antiseptic treatment, and mild radiations applied, chiefly ultra-violet rays supplemented with occasional small doses of x rays. The condition completely healed and for a considerable time the patient remained well. When seen last, about a year ago, he was perfectly well.

#### CASE II.—Actinomycosis.

The following notes of a case of this class are interesting.

A man, aged about 50, was sent for treatment with a history of an operation to the lower jaw and subsequent development of a glandular mass in the submaxillary triangle. A piece of the growth removed was reported as being inflammatory in character.

When seen at the Cancer Hospital in June, 1925, there was a glandular mass behind and below the angle of the lower jaw, the surface was irregular, and in places presented a pustular appearance, though no pus could be found exuding from these spots. The patient was told to foment the mass and to present himself when pus was found to exude. The report (pathological) pointed to a diagnosis of actinomycosis. Two doses of x rays led to a rapid improvement in the appearance of, and a diminution in, the size of the tumour. The lower jaw when x-rayed showed the appearance suggestive of actinomycosis of the bone; the glandular mass was secondary to this lesion. The patient was put upon potassium iodide, etc. The glandular mass is slowly subsiding under combined treatment.

#### CASE III.—Sarcoma of the Right Tonsil.

This case of sarcoma of the right tonsil with secondary glands in the cervical region and mediastinum was treated on similar lines to the technique described, and gave a satisfactory response for a time. In addition to x rays, radium was applied to the enlarged tonsil on two occasions. The glandular condition cleared up and the tonsillar enlargement practically disappeared. (Figs. 3 and 4.) The patient developed mental symptoms, and while being treated for this condition the radiation treatment had to be suspended. He died some time later, presumably from an exacerbation of the original condition.

#### CASE IV.

A man, aged 48, attended the hospital for the treatment of a malignant condition of the nasopharynx, and secondarily enlarged glands at the angle of the lower jaw on the right side. Previously to coming to hospital he had attended at Charing Cross Hospital, and was operated upon there for disease of the antrum. Mr. Davis, who performed the operation, stated that he found a growth in the nasopharynx, but it could not be removed. No section of the growth was made.

The patient was treated with x rays in the following way: To the glandular enlargement doses were given at frequent intervals. The beam of rays was directed in each instance towards the nasopharynx, in the hope that the growth there would get a percentage of the dose. The voltage was 135,000. A filter of 0.1 mm. of lead was used, and 2 cm. of wax placed on the skin. Sixty minutes' exposure to this radiation was given; the total pastille dose for these conditions would be 5½ hours. The first dose was given on March 11th, 1926. On the following dates, March 17th, 24th, 31st, and April 7th, doses of thirty minutes each were given.

The nasopharynx was blocked with polypi, of which Sir James Dundas-Grant removed portions. The glands diminished in size after three exposures. The type of radiation was now changed. On April 14th he was given one-third of an hour's exposure to radiations of 160 kilovolts filtered through 1½ mm. of copper, 2 mm. of aluminium, and 1 mm. of celluloid, with 4 cm. of wax, directed through the same area as before. This dose was repeated on several occasions.

The patient was sent to Mr. Davis, who reported that the trouble in the nasopharynx was practically gone, and commented on the fact that the rays had done a great deal for the patient. Sir James Dundas-Grant also reported on the condition about the same time as follows: "Less polypoid excrescences in right nostril anteriorly; by posterior rhinoscopy there is nothing beyond a little thickening round the right Eustachian tube, serous exudation from the right tympanum; hearing improved by inflation."

The treatment was continued, and on May 28th the following note was made: "Enlarged glands much smaller, can hardly be

felt now." A blood count taken at this time showed practically no change from one taken at the commencement of the treatment. A Wassermann reaction gave a negative result.

At the present date, June 24th, the glandular condition has disappeared, the patient is in good health, and, so far as can be seen, the nasopharyngeal mass has gone.

This case illustrates what can be achieved with x rays alone in disease of the nasopharynx.

#### CASE V.—New Growth of the Larynx.

In this case (a patient sent for treatment by Sir St. Clair Thomson) the diagnosis was open to suspicion, though to a number of specialists who saw the case there was clinically no doubt, and a section removed from the larynx by Sir James Dundas-Grant was shown to be undoubtedly epithelioma. The history and records of treatment are given elsewhere, but for our purpose it will suffice to indicate the general method employed. Voltage about 120,000, filter 8 mm. aluminium and wax on the skin. Weekly doses were given to either side of the larynx and glandular area in the neck. These were continued for a period of several months. The patient made a complete recovery, and remained free from the disease until his death about two and a half years after the commencement of treatment.

An interesting point is that, in spite of the prolonged treatment, no reaction of the skin over the parts irradiated occurred. The enlarged glands in the neck completely disappeared. The progress of the local condition in the larynx from the commencement of the clinical observations to the period of complete healing is shown on the drawings kindly lent to me by Sir St. Clair Thomson. (Figs. 1 and 2.)

### III.—SIR WILLIAM MILLIGAN, M.D.,

Consulting Aurist and Laryngologist to the Royal Infirmary, Manchester; Surgeon Laryngologist to the Manchester Radium Institution.

#### TREATMENT BY RADIUM.

In discussing the treatment of malignant disease of the upper air and food passages by means of radium I labour under the disadvantage of having to confine my remarks almost exclusively to the treatment of surgically inoperable growths—a by no means insignificant proportion, however, of the cases which to-day are brought under our notice.

So far as the treatment of malignant disease in general is concerned—and our own specialty is no exception to the rule—few surgeons have had the courage to employ radium where the growth to be removed appeared to be removable by ordinary surgical procedures, a course of action which at the moment is in consonance with recognized surgical opinion. I venture, however, to say that I look forward to the time when, with improved technique and a more accurate knowledge of dosage and duration of exposure, radium will be used in the type of case which to-day the surgeon claims as his very own. For this reason my remarks must in the main be confined to that vast and distressing array of inoperable cases—vast because I think that no one who has carefully studied the subject will deny that cancer is on the increase, and distressing because, were the public educated as to the danger signals of early malignant disease, much suffering would be avoided and many lives saved.

Since the isolation of radium salts in a pure condition in 1903, and its isolation as a metal by Madame Curie in 1911, its employment as a therapeutic agent has been persistently advocated, more especially in the treatment of malignant growths, its beta and gamma radiations having the property of destroying the malignant, while sparing the healthy, cell. In addition, much clinical work has been done, and various changes in the method of its application, and the amount and duration of dose have been effected as the outcome of increasing experience. In the treatment of inoperable carcinomata two schools of thought dominate the situation: (1) those who believe in large doses and short exposures; (2) those who believe in small doses and long exposures.

Having carefully noted in a numerous and varied series of cancer cases the relative merits of both methods, I am myself in favour, in the majority at any rate, of treatment by small doses and long exposures—exposures running at times to ten, fourteen, or even twenty-one days. For such long exposures it is obvious that the element, and not the emanation, must be used, and this has the disadvantage of locking up large quantities of radium for somewhat prolonged periods, so that its employment is only possible when a moderately large supply of the metal is available. The advantage of accurately burying tubes, needles, or seeds, screened or unscreened, in the tissues is so obvious

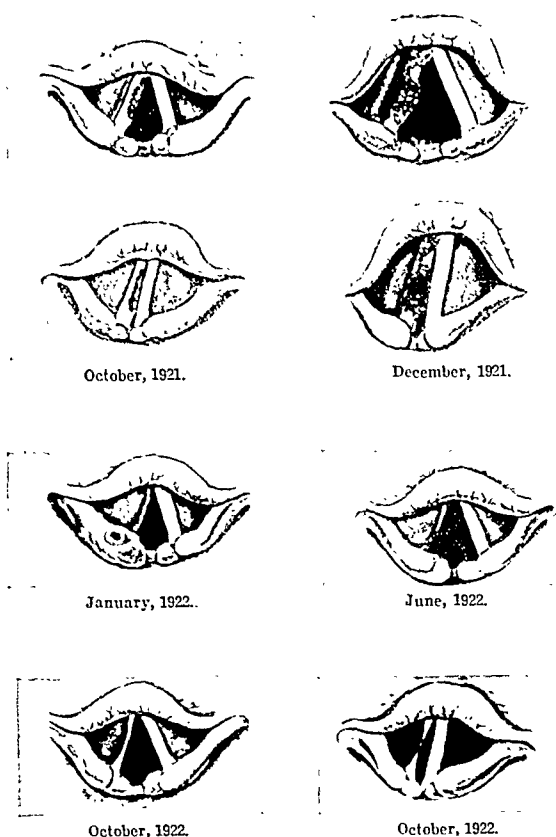

FIG. 1.—New growth of larynx, showing progress and effect of treatment. (Photographed from coloured drawings kindly lent by Sir StClair Thomson.)

H. WARREN CROWE: OSTEO-ARTHRITIS OF THE HIP-JOINT TREATED BY VACCINES.

FIG. 1.—Skiagram of left hip-joint of Case 1 before treatment.

FIG. 2.—Case 1 two years later, after treatment.

FIG. 3.—Right hip-joint of Case 2 before treatment.

FIG. 4.—Case 2 twelve months later, after treatment.

as to require no emphasis, and points to the advisability, whenever possible, of exposing the growth, more especially its base, and under the guidance of the eye inserting tubes, needles, or seeds in an exact and well-thought-out series.

Sarcomata, more especially the rapidly growing variety, are, however, extremely susceptible to small doses of radium applied even for so short a time as twenty-four hours. Their disappearance is at times almost miraculous, but, unfortunately, owing to the seeds of metastasis having already been sown, recurrence at a distance from the primary growth is by no means unknown. In endotheliomata short exposures of from twenty-four to forty-eight hours are often quite sufficient.

In certain situations, such as the nasopharynx or the oesophagus, considerable technical difficulties, due to inaccessibility, confront the operator. In the former an approach to the growth may be made by the lateral nasal route and tubes inserted alone or in combination with other surgical procedures. Another path of approach is by way of the nasal passages with the aid of a special introducer; while yet a third is the introduction of tubes under the guidance of posterior rhinoscopy.

As a means of dealing with malignant growths in the nasopharynx radium offers many advantages. In the first place, from the point of view of prophylaxis it is useful for its devascularizing effects previous to surgical intervention; in the second place, the uncertainty of effecting complete removal by surgical measures, combined with the risk of serious hæmorrhage and the possible occurrence of severe septic otitis media, renders its employment, apart from occasional perforation of the palate or necrosis of the bony walls of the posterior choanae, practically free from risk. The more fibrous the growth, the larger the dose required and the longer the time taken for its disappearance. Growths such as sarcomata, more especially the round-cell variety, conforming as they do to embryonic tissue, are readily dispersed, even with short exposures, by suitable doses of either element or emanation. I have, however, been disappointed at times by the subsequent appearance of serious blood changes after its employment. These blood changes are probably of metabolic origin and not the direct result of radio-activity on the hæmatopoietic organs or cellular elements of the blood.

In that type of sarcoma, round-celled or lympho-sarcomatous, probably arising from glands, and characterized clinically by the appearance of smooth globular swellings in the neck, a fatal issue may result as the outcome of a toxæmia produced by the rapid absorption of the autolytic products of the tumour. In such cases a very gradual absorption of the growth should be aimed at. In the treatment of peritubal malignant growths—growths which as a rule rapidly infiltrate the lateral wall of the nasopharynx—the insertion of radium appears to me to be the most reasonable and hopeful line of treatment to adopt. When the growth is pedunculated, which it rarely is, except in the histologically non-malignant, although clinically malignant, fibromata, surgical removal is indicated; when, on the other hand, it is sessile and infiltrating, surgical intervention is hopeless, while radium has at least a sporting chance.

Whether enlarged glands are present or not, the lymphatic network leading to the first line of defence should be thoroughly saturated with its gamma radiations. If present, and if operable, it is a moot point whether glands should or should not be removed prior to the operation upon the primary growth. After all, they are Nature's first line of defence, and even when infected serve a useful purpose for a time. The immediate effect of the introduction of radium into any growth is to cause considerable reaction in the tissues, increased vascularity and a general oedema, with the probability that malignant cells may commence wandering from their original habitat, to be locked up, however, for a time at least, in the nearest glandular barrier. For this reason I am not now disposed to remove glands in the first instance, as was formerly my practice, but to wait until the period of the first reaction has ended and then to operate. Whenever possible the surgical extirpation of glands should be undertaken. The burial of screened tubes in their substance is scientifically unsound, although it may possibly succeed at

times. The general practice has been to bury tubes in the obviously enlarged nodes, but, as is well known, many small glands exist in the connective and fatty tissues of the involved area, and also at times in adjacent muscular bundles—glands which contain microscopic deposits of cancer cells and which remain entirely uninfluenced. Following the surgical removal of the infected lymph nodes, radium tubes may with great advantage be buried in the lymphatic field for periods varying with the histological structure of the primary growth. External irradiation is also of value, but has to be governed by the tolerance of the skin. It may be effected by placing a collar or frame, to which are attached the necessary number of radium tubes, over the affected area. In addition, the main artery leading to the growth should be tied in order to devascularize the tumour.

Malignant growths in the nose are not very common. Primary carcinoma is somewhat rare, although it so happens that I have myself seen a somewhat exceptional number of these cases. Sarcoma, especially the round-cell variety, is much more common. The varying virulence of nasal sarcomata is known to, and appreciated by, all rhinologists, although I am unaware of any satisfactory explanation of the reason why. The higher up the origin of the growth is in the nasal passages, the worse the prognosis. Although small, favourably situated, and early malignant growths may be treated by one or other form of intranasal operation, access from without—as, for instance, by a lateral rhinotomy—is as a rule preferable, and affords a much better opportunity of radical destruction.

In the treatment of malignant growths of the maxillary antrum and ethmoidal labyrinth—growths usually of the columnar-cell variety—exposure of the tumour should be obtained in the former by a window resection through the canine fossa to facilitate approach and to lessen the risks of extensive necrosis, in the latter by the performance of a lateral rhinotomy. The lines of treatment are the same for growths in either situation and consist in: (1) ligation of the external carotid artery; (2) removal of infected glands; (3) opening of the maxillary sinus or ethmoidal labyrinth; (4) curetting of growth; (5) application of radium; (6) surface radiation. The fact that necrosis may result should not diminish the surgeon's zeal even in the event of deformity resulting—deformity which it is possible to rectify by one or other form of plastic operation, the aim and object of treatment being to get rid of the disease. Sequestra may take months and even years to exfoliate.

Glandular involvement following malignant disease of the accessory sinuses is a late phenomenon. When it occurs the nodes involved are the submastoid and the carotid, and treatment should follow on the lines already laid down.

Malignant disease of the palate is fairly frequently met with. From the surgical point of view it is more often than not inoperable, but lends itself admirably to treatment by diathermy, so much so that I venture to think treatment by radium is rarely called for. In the diagnosis, however, of suspected malignant disease, more especially of the soft palate, I venture to emphasize the necessity of excluding chronic tuberculosis and tertiary syphilis, diseases which at times simulate epithelioma. In this situation glandular involvement is also a late phenomenon.

Primary malignant disease of the tonsil is, in my experience, uncommon, but malignant disease attacking the tonsil as the result of extension from the tongue, the palate, or the faucial pillars, is far from rare and presents one of the most difficult therapeutic problems the surgeon has to deal with. Ordinary surgical intervention is admittedly seldom successful, and is, moreover, very mutilating. The growth is almost invariably a squamous-cell epithelioma highly radio-resistant and particularly difficult to destroy.

In what might be termed favourable cases—that is, where the growth is limited in size and not fixed—the introduction of tubes or seeds may be effected per os, after the extraction of all septic teeth. At least six tubes should be introduced—three from behind forwards and three from before backwards—in parallel series and 1 centimetre apart,

the silk thread from one introduced from behind forwards—being tied to the silk thread of the nearest parallel one introduced from before backwards, so that when tied the tubes are kept, not only in position, but also in parallel planes. The manipulation is, however, unquestionably difficult and requires considerable practice. A more successful plan is the burying of a large number of seeds—ten to twenty or even more—in the substance of the growth. These seeds, usually from 3 to 6 mm. in length and from 1 to 2 mm. in thickness, and containing a dose of from 0.5 to 1 m.c. of emanation ( $=0.5$  to 1 mg. of radium element), are implanted in parallel series 1 cm. apart through the substance of the growth, and either become encapsuled or slough out, the idea aimed at being to effect a wide fibrosis without inducing necrosis or sepsis. One millicurie of radon or emanation emits 132 hours of radioactivity before becoming quite inert.

When the growth is large, infiltrating, and adherent to surrounding structures, it should be exposed from without by means of a subperiosteal resection of the angle of the jaw, a piece of bone at least one inch square being removed. The necessary number of tubes or needles should then be inserted, while later on the whole affected area should be irradiated from the surface by the application of a specially constructed mask carrying radium tubes. Preliminary to resecting the angle of the jaw a ligature should be applied to the external carotid artery, infected glands being dealt with at the time or subsequently at the discretion of the surgeon.

In dealing with malignant growths of the larynx the ordinary classification of intrinsic and extrinsic growths should be borne in mind.

Extrinsic growths—such as growths in the sinus pyramidalis, the arytenoid region, and the epiglottis—may be successfully approached *per vias naturales* with the aid of Haslinger's directoscope. In cases, however, where the growth has extended laterally, it may be advisable, in order to effect an exact introduction of tubes or seeds, to expose the wall of the deep laryngo-pharynx from the outside.

In intrinsic carcinoma where from one or other reason surgical removal is contraindicated, an approach may be secured either through the directoscope or by a window resection of the wing of the thyroid cartilage, or by a laryngo-fissure, the site and extent of the growth determining the exact method of procedure, the thyroid artery having previously been ligatured. My experience is that the implantation of a generous number of seeds into the growth is likely to produce the best results. A number of inoperable cases treated in this way have been free from symptoms for periods of from one to two years.

The performance of a preliminary tracheotomy may or may not be necessary. Speaking generally, it is a convenience and a safeguard, as considerable reaction may follow the insertion of unsecured tubes. As a rule I have found it advisable to perform a tracheotomy when the growth extends below the level of the vocal cords; if above that level it may be dispensed with. A low tracheotomy is advisable and a vulcanite cannula should be inserted. If a tracheotomy is to be performed it should be postponed, if possible, until all manipulations connected with the insertion of radium seeds have been completed. Later on external radiation should be employed with a casted radium applicator round the neck.

The frequency of carcinoma of the hypopharynx, especially in females, is well known and appreciated by laryngologists. Therapeutically it proves a most intractable disease. I have never yet seen a single case in which the insertion of radium tubes or needles has had more than a merely temporary effect.

Malignant disease of the oesophagus presents one of the saddest, the most difficult, and the most disheartening problems the surgeon radiologist has to deal with, and largely because the cases are seen too late. The fetish of what are called nervous symptoms, and the fetish of the bougie, that dangerous and altogether inconclusive instrument, still hold the imagination of large numbers of the profession. By the time obstruction to the passage of the bougie is diagnosed the disease is far advanced. As a matter of actual fact, many cases of malignant disease of

the oesophagus never suffer from obstructive symptoms at any stage of the disease. Squamous-celled epithelioma, the type most usually found in the upper two-thirds of the oesophagus, and adenocarcinoma in its lower third, frequently remain for long local and slowly growing pathological entities, unaccompanied by pain but by the presence of vague symptoms referable to the physiological mechanism of deglutition and by a gradual loss of weight. It is just these vague nervous symptoms which may be the signals of impending disaster and which call for the one and only means of accurate diagnosis—namely, a Roentgen-ray or endoscopic examination. Until the profession grasps this elementary fact there is little prospect of the mortality rate falling below 100 per cent.

The relative inaccessibility of oesophageal carcinoma, whether at the carinal, the hiatal, or the cardiac end of the tube, the absence of a serous coat, and the consequent want of mural rigidity, make effective treatment very difficult. To my mind, any and every form of treatment is enormously helped by the performance of a gastrostomy. To wait until the patient is actually suffering from water hunger and then to perform a gastrostomy is the height of folly. Whatever treatment is adopted—radium, diathermy, or deep x-ray therapy—it will be much helped by the provision of physiological rest to the affected part. As the growth is frequently annular and has infiltrated the sub-mucous tissues, a screened tube attached to a flexible copper wire may be passed down through the stricture and retained in position for the requisite number of millicurie hours. In long strictures "tandem tubes" or hour-glass tubes may be introduced. The accurate introduction of these tubes—and they are of very little value unless accurately introduced—is much facilitated by first of all giving a light bismuth meal and then working with the aid of the fluorescent screen; or an endless thread to which several radium tubes are attached may be swallowed, more especially if the limits of the growth have been ascertained by the method of coulée reversée—in other words, allowing the swallowed bismuth meal to run backwards while the patient is in a reclining position.

In several cases I have introduced radium seeds through a long introducer, but the method is not free from danger, as it is impossible to gauge the thickness of the oesophageal wall, and perforation is not unknown. The therapeutic value of intramural radiation, however, greatly exceeds any extramural method.

Exposure of the cervical oesophagus is quite a practicable procedure if necessary, but exposure of the thoracic oesophagus by a thoracotomy in order to attempt the removal of a growth or to introduce tubes into its substance is a most formidable surgical undertaking, as many here present realized when they had the privilege of watching Mr. Steward at work at Guy's Hospital.

The type of case at present in which radium treatment is generally employed is as a rule so serious and so desperate that results are in consequence far from brilliant. The patient, emaciated, cachectic, and toxic, rejected by the surgeon, but not by the radiologist, grasps at his one and only remaining chance—a chance which too often, unfortunately, is purely transient.

When the profession recognizes the fact that an exact, and not an inferential, diagnosis of oesophageal lesions is imperative if any progress in treatment is to be made—and that such a diagnosis can be made, and can only be made accurately, as the result of an endoscopic examination of the lumen of the tube—then and then only will cases be discovered sufficiently early to admit of the possibility of cure. Endo-oesophageal malignancy starts as a purely local process, is insidious in its onset, and slow in its progress, but it is capable of being accurately diagnosed, both clinically and histologically, by means of modern endoscopic technique.

It is my profound conviction that in the near future the treatment of malignant disease by radio-active substances will take a more and more important position in therapeutics, and that the time will come when radium will be employed in early and operable malignant disease in place of many of the more or less mutilating and unsatisfactory operations performed to-day.

In the successful treatment of malignant disease time

is the great factor. In its early stages the disease is purely local, and, if treated at once, curable. So far I have only had the courage to treat two early and quite operable malignant cases with radium and with radium alone, and in both with excellent results. The assertion that many of the failures with radium in our own particular department of work are due to faulty technique, inadequate exposure of the growth, and inadequate experience, is merely a truism. The haphazard introduction of tubes is not only useless, but is actually provocative of harm.

The radiologist—by which term I mean the radium expert—works to-day under great disadvantages. To his care are relegated as a rule the inoperable and surgically hopeless cases of malignant disease. His chances of brilliant results are few and far between, but that he does get successes and encouragement in his work, even in the desperate cases he deals with, becomes obvious on reading the reports of either the London or the Manchester Radium Institute. In passing I would just mention that a considerable number of the cases he is asked to treat are not even suitable for radium treatment, the extent of the growth and the condition of the patient being such that his experienced and critical judgement negative intervention of any sort.

The conclusions, so far as the treatment of malignant disease of the upper air and food passages by means of radium is concerned, which I venture to place before you for discussion are:

1. That in the present state of our knowledge surgical removal of a malignant growth should be undertaken if a practical proposition.
2. That the lymphatic nodes into which the lymph stream from the growth drains should be removed by dissection or by block dissection.
3. That the lymphatic vessels between the growth and the infected nodes should be irradiated either from within or by external irradiation, and preferably by the former method.
4. That the growth to be irradiated should, wherever possible, be exposed so as to admit of its being handled.
5. That the introduction into the growth of a large number of seeds containing small doses of emanation to be retained *in situ* gives even better results than the implantation of screened tubes.
6. That the implantation of the seeds should follow a definite mathematical plan.
7. That as the periphery of the growth is reached the emanation dose may be reduced.
8. That the main artery to the growth should invariably be ligatured.

Lecturer in Diseases of Throat and Nose, Glasgow University;  
Surgeon, Glasgow Ear, Nose, and Throat Hospital.

#### TREATMENT BY DIATHERMY.

For more than seven years I have used diathermy in the treatment of malignant disease of the mouth and throat—at first timidly and only as a palliative measure in inoperable cases; later, and gradually, operable cases in all stages have been dealt with.

I need not enter into the physics of the method or describe the apparatus in detail, but only deal with the terminals, of which there are two—one consists of a flat leaden plate; the other, like *hors d'oeuvres*, is "various." The former is the static terminal in that it remains where it is placed; the other is dynamic in that it is the terminal with which the operation is conducted. For this latter terminal there are different points—knife, needle, and round and flat buttons of various shapes and sizes. The heat generated at the point of this terminal varies in inverse proportion to its size as compared with the other flat terminal. The leaden plate is wrapped in several layers of lint wrung out of warm saline solution, and is applied to the skin of the patient in the region of the buttock, the patient lying on it; or, better still, I think, one surface of it is smeared with soap and wound round the arm, being kept firmly applied by a bandage. The aim of surgical diathermy is coagulation by heat and not cauterization. When properly used coagulation is obtained

for a radius of a quarter of an inch or more from the acting terminal. Too strong a voltage will result in cauterization, too weak will consume much time in raising the tissues to a sufficient degree of heat.

There are two methods of dealing with the growth. The aim may be to remove it, or it may be to coagulate it, in part or in whole, and allow the coagulated portion to slough away. In all cases in which it has seemed to me that the growth might be removed I have done so, and in this way. With the current off, the diathermy knife is plunged into the tissues beyond the growth, and the current is turned on. At first it takes a little time for the tissues to become heated to a point where coagulation occurs; this is seen by blanching of the tissues around the point and by boiling of the serum or secretion. The current is then switched off and the knife introduced at a little distance from the first place. If the point is withdrawn and introduced with the current flowing cauterization of the surface is apt to occur. This cannot always be avoided, but as far as possible it should be prevented. In this way the whole growth is encircled, and deeply, without regard to structures. Hard bone like the lower jaw will not be destroyed at once, but the part exposed to the heat will come away later as a sequestrum. After coagulation has been produced all round the growth it may be left to slough away, but my practice has been to use the diathermy knife as a knife, and remove it. Where for any reason—and chiefly because it seemed to me that the growth could not be removed—I have adopted the other method, I have dealt with the tumour by means of a blunt point which is applied to the growth in various places, in part or whole extent, according to circumstances.

Though the coagulation will seal up small blood vessels, it cannot be expected to do so with those of large size, and where these are likely to be encountered I always tie the main artery to the part—for instance, the lingual or the external carotid, as a rule the latter. Sometimes it is necessary to tie both linguals or both external carotids. This, too, is a safeguard against secondary hæmorrhage. Sometimes a preliminary tracheotomy is performed. As far as possible the mouth should be put into a healthy condition and diseased teeth should be removed. In short, we must not neglect ordinary surgical principles because we are making diathermy the handmaid of surgery. Chloroform is the anæsthetic; obviously ether is contraindicated.

The treatment of affected glands requires consideration; some surgeons remove these first and then attack the primary growth either at the same time or subsequently, according to the extent of the disease and the length of time required. After removal of glands the diathermy button may be used over the cavity left to seal up the lymph channels as far as possible, though obviously, in the presence of the large blood vessels, this can be only partially accomplished. In the presence of small masses of glandular invasion my practice is to remove the glands at the time I ligature the artery, if I do so. Where the glandular involvement is greater, or where it appears doubtful whether the glands can be removed, I deal with the primary disease first. As a general rule this leads to reduction in the size of the glands, no doubt owing to the removal of sepsis, and their subsequent extirpation is facilitated. In two cases a process of repair seemed to have taken place in the glands, which aroused interest in the pathologists I have, however, in one or two instances found the glandular disease extend rapidly after the treatment of the growth in the mouth. Every case must, in my opinion, be considered on its own merits. Where no obvious glands are present I do not open into the neck, unless to ligature the carotid, when naturally a further search is made. When the mass in the neck is obviously inoperable, and it is decided either to remove the primary growth or to treat it in a palliative manner by the button, puncture of the glandular mass in different places with the diathermy knife or needle may be performed, and I have seen this mass regress decidedly as a result. Naturally the greatest care must be observed as it is impossible to tell in these cases where the large vessels are.

In dealing with malignant disease of the lower pharynx I have in several instances exposed the tumour by the more

usual surgical method, and then treated it by diathermy; in other cases I have made use of the suspension apparatus. Of the two methods I am convinced that the latter is the better where it can be employed. It is almost impossible to close the pharynx again after an extensive use of diathermy, and for the smaller growths the suspension apparatus affords a good exposure. The two methods may be combined. The growth may be treated on the surface by diathermy with the aid of the suspension apparatus so as to mitigate as far as possible the sepsis, and later it may be removed by ordinary surgical methods through an incision in the neck. Here again, however, every case must stand on its merits.

How much should one attempt at one operation? Diathermy, it is conceded, is followed by little or no shock, much less, indeed, than follows operative procedures of equal severity by ordinary surgical methods. Indeed, it is surprising how brisk and well these patients are some hours afterwards or the next day. I am convinced, however, that there is more seeming than reality in this feeling and appearance of well-being. The stimulation has been made at the expense of something, probably the heart muscle. These patients with such advanced sepsis as obtains in serious malignant disease of the mouth and throat are not good subjects, either for prolonged anaesthesia or for protracted operative procedures. Though they appear very well the day after the operation, in three or four days they are, most of them, very much the reverse, and death occurs sometimes suddenly from heart failure. No doubt great care is required in the nursing. Discrimination, however, must be observed in regard to the extent of operative procedure carried out at one time. If the palliative treatment of an inoperable growth is undertaken it is easy to coagulate it in stages, but where it has been decided that there is a chance that a growth may be entirely removed, there is the temptation to complete the operation at once. In some cases, of course, the call is for non-interference: the disease is too widespread and advanced, and the inevitable end too near. In view of the benefit obtained even in advanced and inoperable cases there are very few patients to whom some measure of relief will not be given. The diagnosis of malignant disease of the mouth and throat is another story, much of it tragedy, but in Glasgow, to which patients come from remote districts in the West of Scotland, Highlands, and Islands, some terrible cases of this disease are seen. In other parts of the country, less isolated, I should expect the patients to present themselves or to be sent earlier and at a time when there is no hesitation in advising the use of surgical diathermy with one or other aim.

Extent of the disease is not the only point we have to consider; its position will also determine the prospect of treatment by diathermy. Broadly speaking, this method decreases in suitability as the site of the disease descends from the alveolus to the oesophagus. The cases most suitable are those in which the growth is confined to the mouth, including the tongue, upper jaw, palate, fauces, and floor of mouth. For these I claim that removal by surgical diathermy, or, for inoperable cases, treatment by surgical diathermy, is the method *par excellence*. For operable cases of the lower pharynx, for post-cricoid car-

TABLE I.—Particulars of 122 Cases of Malignant Disease of the Mouth and Throat operated on by Surgical Diathermy, (1922-25).  
(Males 105. Females 16. Ages 34 to 74.)

| Position of Growth.                               | Males. | Females. |
|---|--------|----------|
| Tongue ... ..                                     | 13     | 1        |
| Tongue and floor of mouth .. ..                   | 30     | 1        |
| Fauces, soft palate, tonsil, and (in some) tongue | 25     | 2        |
| Pharynx .. ..                                     | 16     | 5        |
| Upper jaw .. ..                                   | 20     | 6        |
| Oesophagus .. ..                                  | 2      | 1        |
| Total .. ..                                       | 105    | 16       |

Of these cases 33 are alive, 69 are known to have died, and 14 are untraced. The disease was localized in 33, extensive in 60, and otherwise in 29.

TABLE II.—Showing Period of Survival of the 69 Patients who Died after Operation.

| Position of Growth.                      | Under 1 Month. | 1 to 6 Mos. | 6 to 12 Mos. | 1 to 2 Years. | Over 2 Years. |

\* One of these, a male, died of diabetes in March, 1925, three and a half years after operation for epithelioma of the fauces with glandular involvement. There was no recurrence of the malignant disease.

cinoma, and for malignant disease of the larynx, diathermy is altogether unsuitable. In these regions it is only of value as a palliative measure in inoperable cases, in which a great measure of relief has been afforded in a number of instances. In malignant disease of the oesophagus it is possible that with increased experience temporary relief may be given by this method in conjunction with others.

The accompanying tables show the results of treatment in 122 cases which have been operated on during the four years 1922-25.

#### GENERAL DISCUSSION.

Mr. W. G. HOWARTH (London) considered that diathermy was the method of election in dealing with malignant disease in the pharynx and the pyriform fossa, even though it did not appear ideal from the surgical standpoint. He did not think that diathermy removal implied slow healing or increased infection. He was impressed by Mr. Steward's method of feeding through a pharyngeal tube introduced through the wound. If surgical removal was contemplated and the patient had carious teeth, he would allow three or four weeks to elapse after their extraction before operating; if the teeth were sound then operation need not be delayed.

Mr. MUSGRAVE WOODMAN (Birmingham), referring to the use of diathermy, said he had had sixty patients with oesophageal disease under his care during the last three years, and had operated 105 times. He had not cured a single case, and he was not even sure that he had been able to prolong life to any appreciable extent. In nearly all instances he had been able to keep the patient eating ordinary food *per vias naturales* until death ensued from extension of the disease. The results were superior to those of gastrostomy, and throughout the disease that patient was able to swallow freely by the ordinary route. The operation was well borne, produced very little shock, and the patient left the hospital two or three days afterwards, eating and swallowing well, and in good condition. The present value of diathermy in the oesophagus was limited by the anatomy of its situation. In the absence of a peritoneal coat and of any fibrous tissue in its wall, it was extremely difficult to produce artificially an irritant fibrosis around the oesophagus sufficiently dense to prevent leakage during the time the growth was being destroyed. In experimental work on monkeys he had injected warm paraffin wax and suspensions of silica in glycerin, and had transfixed the oesophageal wall with electrolytic needles. In every case at the *post-mortem* examination of the animal no trace of the injected material was found and no resulting fibrosis was produced.

Dr. WILLIAM HILL (London) gave a lantern demonstration of his special radiumtherapeutic apparatus and technique, and showed the radiographic appearances in selected cases of malignant strictures before and after radium applications. If, for example, an annular stricture was about an inch long, a silver cylinder 1 mm. thick, as used at the Radium Institute, could be employed enclosing a capillary tube 3 cm. long containing either a pure radium salt or else radon, with an emanation equivalent of radioactivity equal to that of 50 mg. of radium bromide—

approximately 25 mg. of radium element to each centimetre in length. This apparatus so charged could safely be retained in the stricture for fifteen hours, more or less, according to the thickness of the growth. The silver style kept the radon cylinder down in the right place on the stricture, and the special collar in Dr. Hill's apparatus prevented it being pressed down beyond the thick hardened upper collar-like end of the stricture. The question of dosage was discussed as regards the weight dose per centimetre length, the screen dose, the time dose, and the repetition dose. Dr. Hill had made over 400 applications of radium salts or of radon in cancerous stricture in the throat and gullet, and had found that about a third of approximately one hundred patients so treated had exhibited very remarkable temporary improvement, one-third substantial improvement, and yet another third were either not obviously benefited or else were rather worse, either from the incidental manipulative interference or from a massive toxic effect very exceptionally induced by radium. Dr. Hill also showed twenty-four slides relating to twelve selected cases, radiographically demonstrating the difference in the size of the lumen of the strictured gullet before and after radium or radon applications. The lives of a certain number of patients had been prolonged with comfort for periods varying from one and a half to three years. In one exceptional case (the radiograms of which were also shown on the screen) the patient had ten applications with Dr. Finzi's radium in the course of two years, and lived normally a further five years (seven in all) with apparent temporary local cure of the primary gullet lesion up to the time of death, which was due to sudden activity in long quiescent small secondary deposits in the liver and abdominal glands. Palliative success depended on exact knowledge and experience of the technique of radium therapy in cancer of the gullet as in parallel measures elsewhere. Loose work by inexperienced persons had brought discredit on this form of therapy in the past and would do so in the future.

Professor VON NEUMANN (Vienna) stated that he injected intravenously 30 c.cm. of a 30 per cent. solution of dextrose before operating.

Sir JAMES DUNDAS-GRANT (London) said that the necessity for exact diagnosis emphasized by Dr. Knox was illustrated by the case of cure of intrinsic epithelioma. It was originally diagnosed as tuberculosis, and the speaker's removal of a portion for microscopical examination indicated the nature of the disease only just in time to save the patient's life. He strongly recommended the early adoption of this method of diagnosis. He stated that simple polypi frequently occurred in the course of malignant disease of the ethmoidal cells, and that the report as to their simplicity should not mislead the examiner. In diathermy the bipolar method was useful. More delicate non-conducting retractors were to be desired. It had to be remembered that ligation of the external carotid artery was occasionally followed by cerebral embolism. In comparing laryngo-fissure with laryngectomy, the speaker called attention to the danger if the patient fell subsequently into water. Laryngo-fissure should always be given the preference, as was usual with British operators.

Mr. E. B. WAGGETT (London) believed that when the jugular vein had to be ligatured it should be resected; in a very promising case in which he had failed to do this the patient died with pulmonary embolism. Post-operative feeding of such cases by a tube inserted through the pharyngeal wound might result in parotitis. It was desirable to give the patient chewing gum to obviate stagnation of secretion in the salivary ducts. Extensive dentistry upon septic sockets might be followed by Vincent's ulceration of the tonsil. It was therefore advisable not to fix a date for the major operation until some days had passed after the dentistry.

Mr. ANDREW WYLLIE (London) had found that patients suffering from malignant disease of the throat or oesophagus were usually of a placid nature, and he did not use a general anaesthetic in diathermy. A dose of morphine was given before the operation; both electrodes

were put into the growth, and the patients could sit up immediately after leaving the theatre. He considered that by this method there was less danger of unfortunate sequelae, such as secondary haemorrhage, and had never known of evil after-effects. Very few patients suffering from malignant disease in this situation had sound teeth. He advised every tooth to be extracted two weeks before operation.

Mr. C. A. S. RIDOUT (Portsmouth) emphasized the importance of treatment of oral sepsis before operation for malignant growths of the mouth and pharynx. He thought diathermy was the operation of election for malignant growths of the tongue, fauces, and palate, and emphasis was laid on the value of, and lack of risk in, previously tying the external carotid artery. His experience of treating certain growths of the hypopharynx by diathermy, especially in the neighbourhood of the pyriform fossa, by endoscopic methods was not unsatisfactory. Early gastrostomy was useful in cases of malignant ulceration of the oesophagus, and the consequent improvement in the condition of the ulcer was an aid to further treatment.

Mr. HERBERT TILLEY (London) said that his experience in malignant disease of the nose and its accessory cavities had led him to believe that it was better practice to remove the primary disease as far as possible by surgical measures and then to employ radium or x rays afterwards. If radiotherapy was instituted in the first instance, there was the danger that the patient's system might be flooded by the toxins of broken-down growth and inflammatory products. This was by no means improbable in a large closed cavity like the maxillary antrum. Diathermy was an invaluable agent in malignant disease of the readily accessible regions of the mouth and throat, and he had been struck by absence of inflammatory reaction in the normal tissues immediately surrounding the large sloughs on those areas which had previously been occupied by a new growth. Coincident with this was the almost complete absence of shock or other systemic reaction.

Mr. NORMAN PATTERSON (London) considered that a preliminary gastrostomy was a great advantage in that the general condition of the patient was improved thereby and that post-operative feeding was more comfortable and effective.

Dr. W. JOHNSON HORNE (London) thought that the importance of accuracy in diagnosis before the commencement of treatment could not be overstated. Of all diseases malignant disease was the one that was diagnosed more often than it existed. He mentioned the frequency of erroneous diagnosis of a chronic inflammatory or granulomatous condition in the nose or a tonsil as sarcoma. The result was an increase in the number of cases of malignant disease of the upper air and food passages, and a corresponding increase in the number reported as being cured of cancer. Going back to before the days of x rays, radium, and diathermy, there might be some present who remembered the prominence given in the press to the "violet leaves cure of cancer." The patient, a lady, had been troubled with a throat affection; finally a diagnosis was made of inoperable malignant disease of the tonsil. The patient had resigned herself to her fate when a sympathetic friend suggested treatment with violet leaves, which, in view of the verdict that had been passed, could do no harm. Violet leaves in form of poultices, or compresses, or gargle, or tea, were used, and recovery followed—*post hoc* and not *propter hoc*. This "cure" was taken up by the press. The pathological sections were examined microscopically, and a chronic inflammatory or granulomatous condition was then diagnosed. In the present day of treatment by diathermy an erroneous diagnosis would probably escape notice.

Mr. L. COLLEDGE (London) said that if septic teeth were present with an obviously foul mouth, and the patient declined to have them extracted, it was better to refuse to operate as the patient would die. If the patient had sound teeth the conditions were better, but primary healing was unlikely. The case was more favourable if the patient

was edentulous, but the most favourable condition was when the mouth had been cleared of septic teeth about three weeks previously. The immunity of the patient seemed then to be highest, and primary union without leakage or sloughing might be obtained.

Mr. F. J. STEWARD, in reply, said that his experience did not coincide with Mr. Colledge's on the dental question. He would have all septic teeth removed before operation, but he had not found that the presence of sound teeth had militated against primary union. In regard to diathermy, he would stress the importance of an adequate exposure of the growth before applying the electrodes, and of the preliminary removal of glands, if surgically possible. He had not found that diathermy was unsatisfactory in malignant disease of the deep pharynx or in extrinsic laryngeal growths; rather the reverse. His rule was to remove small growths surgically and large ones by diathermy.

Dr. KNOX, in reply to the question raised regarding the term "lethal dose," said it was necessary to realize what was meant by the lethal dose in reference to malignant disease. The generally accepted explanation was that given by Seitz and Wintz of Erlangen, who, in their valuable work, laid down the rule that if the erythema dose was taken as 100 per cent., the lethal dose for cancer worked out at from 90 to 110 per cent. of the erythema dose. This had been found to be more or less inaccurate; the lethal dose for cancer might vary in wide degrees from that estimate, and in practice it had been found that if the lethal dose was given, the response was not invariably a favourable one. The method of estimating the dose at the depth was, however, based on the work of Seitz and Wintz, and it might be used as the standard of measurement of the depth dose.

Sir WILLIAM MILLIGAN rather doubted the benefit to be gained from preliminary gastrotomy. He would always remove a removable growth surgically and use radium subsequently to prevent recurrence. He only allowed patients in the sitting-up posture when they were quite out of the anaesthetic.

Dr. W. S. SYME said that in discountenancing the use of diathermy in malignant disease of the pharynx he was thinking rather of the larger growths, and the virtual impossibility of closing the pharynx. He was not inclined to remove a large growth by diathermy without an anaesthetic.

## SECTION OF ORTHOPAEDICS.

E. MEHRHEAD LITTLE, F.R.C.S., President.

### DISCUSSION ON

### NON-TUBERCULOUS COXITIS IN THE YOUNG.

#### OPENING PAPER

BY

H. A. T. FAIRBANK, D.S.O., M.S., F.R.C.S.,

Senior Orthopaedic Surgeon, King's College Hospital, London.

LAST year a discussion took place in the Orthopaedic Section of the Royal Society of Medicine on the differential diagnosis of non-tuberculous coxitis in children and adolescents. In the admirable paper with which he opened that discussion, Mr. Alan Todd raised points of great interest and importance: upon these points those who heard his paper or read it afterwards have now had ample time to ponder. At the request of the President of this Section I shall endeavour to cover the same ground as was covered in the discussion at the Royal Society of Medicine last year, confining my remarks to the affections of the hip-joint met with in children and adolescents.

Now, I take it that, speaking generally, coxitis arises either from trauma or from infection. By trauma I mean the repeated minor injuries incidental to anatomical abnormalities, whatever the cause of these may be, which involve a want of fit between the head of the femur and the acetabulum, as well as violence applied directly or in-

directly to the joint from without. There are affections of the hip-joint, I admit, the exact nature of which is still in doubt, and in which the part played by infection has yet to be decided. For instance, what is the cause of pseudo-coxalgia, or of arthritis deformans juvenilis? We could spend a whole morning discussing either of these; I must content myself with brief references to them later. The subject of this discussion is so vast that it is only possible to touch on many of the interesting problems that present themselves. It will be my endeavour to clear the air, if I can, on some of the points raised in the previous discussion, and to invite the opinion of others upon some of the many debatable questions that are met with in the consideration of the various affections included in the title of this paper. As a basis of discussion I have drawn up the following classification of the common affections which may, I think, be legitimately included in "non-tuberculous coxitis."

#### Non-tuberculous Coxitis.

1. Traumatic synovitis and arthritis.
2. Traumatic synovitis and arthritis with adolescent coxa vara.
3. Infective arthritis—acute, subacute, and chronic. (Sub-section—arthritis secondary to osteomyelitis.)
4. Acute rheumatic arthritis.
5. Rheumatoid arthritis (Still's disease).
6. Pseudo-coxalgia.
7. Coxitis complicating congenital dislocation of the hip: (a) Villous; (b) Absorptive; (c) Osteo-arthritis.
8. Arthritis deformans juvenilis.

It may be noticed that this classification differs in some respects from that of Mr. Todd. For instance, "coxitis of secondary onset" has been entirely left out. Surely infective coxitis, whatever the causative organism, whether this be the tubercle bacillus or one of the pyogenic organisms, is invariably secondary to some other lesion, though this primary lesion from which the blood-borne infection arises may not be easily found. Then again, the nature of the arthritis depends on the particular organism responsible for it, and upon the virulence of that organism, and not upon the mode of entry of the infection. Arthritis of the hip in a case in which the mode of infection is obscure is precisely the same disease as arthritis that follows appendicitis or a sore throat. Those cases of arthritis of the hip-joint which begin as an acute osteomyelitis of the femur—or more rarely of the pelvis—might legitimately be called secondary, I agree, but they are only a variety of acute suppurative arthritis and should, I think, be considered under this heading. I cannot help feeling that we are in danger of multiplying the varieties unduly, and I would suggest that we should aim at simplification in our grouping of the cases and should avoid adding to our classified list until we are certain that a particular type of case really deserves a separate heading. No doubt future experience will lead to a further grouping, as has happened in the past, but it behoves us to be wary that any such separation of a group of cases is really justified on clinical or bacteriological grounds.

#### 1. Traumatic Synovitis and Arthritis.

It is sometimes forgotten—probably because of the difficulty of palpating the joint as compared with the knee, for instance—that the hip-joint is subject to synovitis as a result of a strain. There is little doubt that this is the true diagnosis in many cases of pain and disability, following trauma.

Limitation of movement in such a case usually does not involve all movements, and complete recovery follows, as a rule, in a few days with simple rest in bed without a splint or extension. Some even recover without any rest at all. In one or two such cases lately the radiogram has revealed the presence of an oval piece of bone opposite the outer part of the anterior margin of the acetabulum. This loose fragment of bone may be in a definite notch in the margin of the socket, and it is suggested that it may be a sesamoid in the reflected head of the rectus femoris. Is it possible that the presence of a loose fragment of bone in this situation, whatever its nature, renders the part more liable to strain?

A boy, aged 13, sprained both hips when jumping, at the age of 5 years, the left being the worse; he was laid up for three months. Eighteen months later the right hip again gave trouble, laying him up for a month. He was quite well till a week

before he was first seen, when he strained the right hip while running. Since then the hip had ached a bit and was worse if he walked. He said the hip was a bit stiff. On examination there was no limitation of movement in the hip, but full flexion and extension caused pain and there was some tenderness over the front of the joint. X rays showed a fluffy piece of bone near the upper lip of the acetabulum on each side. The acetabular shadows on both sides were distinctly irregular, but the heads of the femora were smooth and rounded.

The appearance of these two fragments of bone in this case does not, it is admitted, strongly suggest a sesamoid bone, but the situation is the same as in others in which the regular oval shape of the bone fragment is much more suggestive of a sesamoid. It may well be that all loose fragments in this situation have not the same origin. Abnormal ossification of the acetabulum would seem to be at any rate uncommon. We hope to hear whether others have met with this condition associated with symptoms referred to the joint. Juxta-epiphyseal strain should, I think, be regarded as the initial stage of an adolescent coxa vara; it is considered under this heading below.

## 2. Traumatic Synovitis and Arthritis with Adolescent Coxa Vara.

This group is so well recognized that little need be said about it. The cases are preceded, as a rule, by more definite trauma than in the preceding group, and are distinguished by limitation of abduction, raising of the trochanter, and shortening, to some extent at any rate, while the x-ray pictures are characteristic. In the early stages, the juxta-epiphyseal strain of some authors, there is widening of the epiphyseal line—the head of the femur appears to be loosened from the neck—and there is always a little displacement which accounts for the shortening. It is hardly necessary to emphasize the importance of recognizing and treating these cases in the early stage and thus preventing gross displacement of the femoral head. Mistakes can only be avoided by invariably looking for this lesion and making a minute comparison of the shadows thrown by the two hips. These early cases complain of a limp and pain on walking, beginning immediately after the trauma, but may show no limitation of movement, not even of abduction, though a slight degree of shortening is always present.

When gross displacement is taking place, or has taken place fairly recently, traumatic arthritis with its accompanying spasm limits the movements of the joints more or less completely. It is this condition which is so often mistaken for tuberculosis, in spite of the fact that the limb is not flexed but is markedly everted, and the trochanter is already raised well above the normal level. If the normal anatomy is not restored—and this, unhappily, is rarely possible—the joint is permanently damaged and is susceptible in a marked degree to osteo-arthritic changes.

## 3. Infective Arthritis—Acute, Subacute, and Chronic.

The acute case with a high temperature and a polymorph leucocytosis gives little difficulty in diagnosis. Common organisms are the staphylococci, streptococci, and pneumococci. All degrees of virulence of the infecting organisms are met with, particularly, I think, the staphylococci. The same pyogenic organism can cause all grades of arthritis, even, occasionally, in the same patient. One inflamed joint goes on to suppuration while another in the same patient remains dry. A well marked case was met with in an adult some months ago.

A man, aged 50 (under the care of Dr. Fraser), developed an acute arthritis of one hip, with a very high temperature and leucocytosis. The hip-joint was opened and found to be bone dry, yet a culture grew pure *Staphylococcus aureus*. The joint was closed, and the wound healed by first intention and remained healed. Erosion of the cartilage surfaces was present and this progressed during the following weeks. The swinging temperature continued and the knee on the same side became affected. After a few weeks a small abscess was opened on the inner side of the knee and from this *Staphylococcus aureus* was grown. Eventually the knee was freely opened and the patient recovered with ankylosis of both joints.

Recently we have seen a case with acute osteo-mylitis of one femur and acute non-suppurative arthritis of the opposite hip-joint.

A boy, aged 4½ (under the care of Dr. Grosart Wells), developed acute osteomyelitis of the lower end of the left femur. This was

operated upon, and *Staphylococcus aureus* grown from the pus. Almost from the first the child complained a little of the right hip. This joint was eventually opened and was found to be dry, so the wound was closed. It healed and remained healed. Two weeks later x rays showed subluxation of the head of the femur, which rather suggests that at one period the capsule had been distended, the fluid becoming absorbed later. The subluxation was easily reduced by extension and gradually increased abduction.

This is not the place to discuss in detail the treatment of acute arthritis, but one or two points may be touched on. If the hip requires opening at all, I believe in obtaining thorough drainage. This necessitates the making of a posterior incision, whether the joint has been first opened in front or not, but it does not involve the insertion of a tube beyond the opening in the capsule. When, however, the child is young, the signs and symptoms rather subacute, and the fluid in the joint thin and flaky, a pneumococcal infection may be suspected, and the wound may be closed after a thorough irrigation of the joint with saline, with a fair prospect of success.

Another point which I venture to emphasize in connexion with acute arthritis of the hip-joint is the importance of maintaining abduction for several weeks in order to avoid dislocation. Retention of abduction for four weeks, for instance, is not long enough. After a minimum of four weeks' abduction with extension the limb should be retained in abduction by a plaster case for at least another two months. Dislocation is extremely common without any gross erosion of the bones having occurred, both when the joint has been drained and when it has been washed out and closed, and it may even occur without the joint having been opened at all.

Brief reference must here be made to coxitis secondary to osteomyelitis of the femur. The exact diagnosis in these cases is often extremely difficult, not only as regards the presence or absence of an infection in the bone, but also, when this is certain, as to the condition of the joint. When an acute infection starts in the head or the neck of the femur arthritis is always present by the time the case is operated upon, but when the disease begins near the epiphyseal line of the greater or lesser trochanter the possible involvement of the joint becomes a question of the first importance. If aspiration, through unbroken skin, fails to yield conclusive evidence as to the condition of the joint in such a case, I think the bone lesion should be freely dealt with and the patient watched. If after a couple of days the state of the temperature and pulse and the local signs still give cause for anxiety, the joint should be opened and drained.

I have long believed that a mild strain of staphylococci accounts for many cases of subacute and chronic non-suppurative arthritis, with or without erosion of the joint surfaces, but it is difficult to prove this. It is, of course, the subacute or chronic case which causes us the greatest difficulty in diagnosis. For instance, we commonly see patients with definite signs of arthritis of one hip, the symptoms having been present only for a few weeks, with little or no temperature, and negative x-ray findings. The joint is flexed and abducted and movements are restricted or obliterated in all directions. Although considered to be non-tuberculous, such a case, in my opinion, requires immobilization, preferably with extension, and a fresh x-ray examination after a month; and this should be repeated again after a further month if necessary. The usual sources of infection, particularly the tonsils, are examined, and, if necessary, dealt with radically. Time is necessary to clear up the diagnosis. If non-tuberculous, all spasm has usually disappeared in four to eight weeks, and radiograms are still negative. The child is kept in bed without fixation for a few days, and then allowed up, the recovery usually being complete and permanent. Occasionally recovery is delayed and some doubt as to the nature of the case remains; removal to the country—if this has not already been done—for a further period of fixation is then necessary.

What is the nature of the infection in these cases? In my opinion it is probably staphylococcal. The von Pirquet reaction I do not rely upon. A positive reaction is useless; a negative reaction deserves to be considered as a link in the chain of evidence.

Another question upon which I would invite discussion

is this: Is an attack of measles sometimes followed by coxitis with special characteristics which distinguish it from other forms of arthritis of the hip-joint? Non-tuberculous coxitis appears to be a distinctly uncommon sequela of measles, while tuberculous hip disease is more often met with. Careful inquiry among my colleagues at the Hospital for Sick Children, Great Ormond Street, showed that, without exception, their experience agrees with my own. We have no reason for thinking that there is a special form of arthritis associated with measles. When coxitis follows an attack of measles, and is non-tuberculous, it is the result of infection by one or other of the common pyrogenic organisms, and this arthritis differs in no way from that caused by the same infections in other patients.

With regard to scarlet fever, the question is rather more difficult. Arthritis in the early convalescent stage of this fever is much more common than after measles, and often takes the form of "rheumatism," which is said to have special features of its own by those with the greatest experience of infectious fevers. While simulating ordinary acute rheumatism in some ways, it differs in certain important respects. There would appear to be, however, no clear line to be drawn between cases of the rheumatic type and those in which the arthritis goes on to suppuration; and it appears to be reasonable to suppose that the presence in the joint of toxins only or of actual infection with streptococci of variable virulence accounts for all the forms of arthritis met with after scarlet fever, and that these are similar in every way to grades of arthritis met with apart from this particular infectious disease.

A few words are necessary on the relation of infected tonsils with arthritis of the hip. Few will question, I think, that the throat (and mouth generally) not uncommonly provides the path by which micro-organisms enter the body and cause acute coxitis, and also that there are cases in which arthritis of the hip-joint, less often perhaps than of other joints, has cleared up rapidly after a "spring clean" of the throat, nose, and teeth. The exanthematous fevers unquestionably favour the entrance of organisms by these paths. I would, however, dispute the correctness of regarding coxitis following the removal of tonsils and adenoids as a not very uncommon occurrence—common enough, in fact, as suggested by Mr. Todd, to warrant special mention in a class of "secondary coxitis." Our combined experience at the Hospital for Sick Children—and this experience runs into very many thousands of operations on the throat—fails to provide a single case of arthritis following enucleation of the tonsils. We have, it is true, seen cases of arthritis arising at varying periods subsequent to removal of the tonsils and adenoids performed elsewhere, but invariably such cases were found to have masses of septic tonsil still present in the fauces, necessitating a second operation. I know of one solitary case, that of a medical man, where a mild coxitis followed total removal of the tonsils by a first-class throat specialist.

#### 4. Acute Rheumatic Arthritis.

Acute rheumatic arthritis need only be mentioned. It forms a group with such characteristic clinical features and complications that it is convenient to continue to separate it from other forms of infectious arthritis.

#### 5. Rheumatoid Arthritis (Still's Disease).

Rheumatoid arthritis may present difficulties in diagnosis in the early stages when the hips are the first joints to be affected, but this would seem to be a rare occurrence. The involvement of other joints before long (the cervical spine being often affected early in the course of the disease), the enlargement of the lymphatic glands and spleen, and the x-ray appearances, should make the diagnosis clear.

#### 6. Pseudo-Coxalgia.

The characteristics of this affection are becoming so well known to all branches of the profession that mistakes in diagnosis are now far less common than they were. The radiographic change typical of this disease may, however, be closely simulated for a time by other affections of the joint, notably tubercle. It behoves us, therefore, to

treat as tuberculous any doubtful case until time and further x-ray examinations make the diagnosis clear. May I be allowed to remind you that there are two clinical stages of pseudo-coxalgia in which the differentiation from tuberculous coxitis may be difficult and the help of a first-class radiogram essential. First, when limitation of movement involves abduction only, or abduction and internal rotation, the case may suggest the pre-arthritis stage of tuberculous coxitis; by this I mean the stage in which a tuberculous deposit is present in the neck of the femur or beneath the acetabular cartilage, but in which as yet there is no general arthritis. The healthy condition of the child, and perhaps an entire absence of pain, may suggest a non-tuberculous diagnosis, but often the radiograms have to be relied on to decide this matter. Secondly, when spasm limits all movements in pseudo-coxalgia, tuberculous arthritis may be closely simulated. The diagnosis must depend on the points mentioned above; the rapid disappearance of the spasm on immobilization with extension is in favour of pseudo-coxalgia.

#### 7. Coxitis complicating Congenital Dislocation or Subluxation of the Hip.

The arthritis which is discovered within a few weeks or months of reduction of a congenital dislocation seems to be essentially traumatic in origin, but that a mild infection plays a part, in some cases at any rate, is rather being forced upon us by further experience. It is certainly wise to postpone reduction in children not in perfect health, and any obvious infective foci that are found must be eliminated in all cases before operation is proceeded with. With regard to the cases that for one or other reason have been left without treatment, I cannot help feeling that the opinion, which would seem to be pretty general, that the onset of pain and increasing disability at a comparatively early age is inevitable, is hardly justified. Though difficulty in walking may increase long before a patient is fully grown, particularly in bilateral cases, a fair number of cases are met with in adult life with surprisingly little discomfort referable to the hip-joint. It is my belief that the pain from which many of these cases, at any rate, sooner or later suffer is due to arthritis rather than to mere static conditions. Further investigation on this point is urgently required, if our methods of treatment are to be on the right lines. Villous arthritis has been found in an untreated dislocated hip in a girl of 13 years who could not walk more than a few hundred yards. The radiogram was negative to any obvious arthritic change. Is this form of arthritis the usual cause of the pain in the cases which show little or nothing in the way of erosion or lipping of the femoral head? If this suggestion—and it can be nothing more than that at present—is correct, the formation by operation of a bony shelf above the displaced head is surely unlikely to afford relief of the symptoms. On the other hand, gross absorption of bone and flattening of the head of the femur may occur. These changes we see more particularly in untreated subluxations, and especially after reduction in a child rather older than is desirable, both when the reduction has been successfully maintained and when a partial relapse has occurred. This type some years ago we ventured to call "absorptive arthritis"; the loss of tissue may be extreme—enough to suggest a neuropathic joint.

Lastly, osteo-arthritis—and this constitutes one form of arthritis deformans juvenilis—may develop whether the dislocation has been treated or not. This type is met with typically in adults with a poorly formed acetabulum and only the smallest degree of displacement of the femur. The underlying congenital defect is sometimes overlooked.

#### 8. Arthritis Deformans Juvenilis.

With regard to this form of arthritis, we may usefully ask ourselves whether it ever occurs as a primary affection of a previously normal joint. Though it is probable that it may occur in rare cases as a primary affection, with or without antecedent trauma, it is, I suggest, substantially true to say that juvenile osteo-arthritis affects a hip which has been definitely damaged anatomically by trauma or infection, or is the seat of a congenital malformation. It

is hoped that we shall learn whether this statement is supported by the experience of others. It is possible that our conceptions of what is meant by this title differ somewhat, so it is perhaps advisable to state exactly what I mean. In my view arthritis deformans juvenilis is simply osteo-arthritis occurring in a patient far below the usual age at which we commonly meet with it. It is a chronic arthritis associated with pain, progressive limitation of movement, and deformity. The pathological changes, as revealed by x rays, are slow erosion with a decided tendency to "lipping" at the articular margins. The conditions which favour the onset of these osteo-arthritic changes in the young are congenital subluxations, unstable hips with imperfectly formed acetabula, adolescent and traumatic coxa vara with permanent displacement of the head on the neck of the femur, fracture of the femoral neck with or without union, pseudo-coxalgia, acute arthritis, particularly when complicated by pathological dislocation requiring replacement, and no doubt others. Whether the secondary arthritic changes are due to infection in addition to chronic trauma is uncertain, but it would appear probable that infection plays a more important role in those cases, such as Mr. Harry Platt describes in his paper on pseudo-coxalgia, in which the arthritis seems to be primary. My impression is that these last have a decided tendency to be bilateral. I have met with it once in a female of 16; the radiogram in this case shows a remarkable symmetry in the deformation of the two femoral heads.

There are other forms of coxitis occasionally met with that are difficult to classify. For instance, we have seen a bilateral case in which the x-ray changes were confined to the inner or lower part of the two joints. These rarer types are, I think, better left out of the discussion to-day. Gonorrhoeal, meningococcal, typhoid, and dysenteric arthritis, particularly of the hip, are so uncommon in children that they need only be mentioned. Haemophilia affecting the hip-joint I have not seen. An effort has been made at least to refer to all the common groups of cases, and to call attention to some of the points which seemed to me most worthy of discussion.

#### GENERAL DISCUSSION.

Mr. S. W. DAW (Leeds) considered Mr. Fairbank's classification of non-tuberculous coxitis a very good one, but he suggested that the last group—arthritis deformans juvenilis—might be omitted, as he was not yet satisfied that it existed as a separate primary entity, though a condition of this type might follow any of the other groups, except, perhaps, acute rheumatism. It was often difficult to fit cases of hip trouble into any of the recognized groups; it was better to leave these ungrouped until there was more certainty, and he suggested that arthritis deformans juvenilis should be allowed to remain unclassified. In rheumatoid arthritis (Still's disease), difficulties of diagnosis in the earlier stages were perhaps due to imperfect observations, and Mr. Daw described two cases to illustrate the fact that the development of multiple joint lesions might be slow. It was sometimes difficult to distinguish pseudo-coxalgia from tuberculosis, but it was nearly always the case that in pseudo-coxalgia the x-ray developments were in advance of the clinical symptoms, whereas the reverse obtained in tuberculosis. Many patients with congenital dislocation of the hip continued for a long time with very little pain.

Mr. S. T. IRWIN (Belfast) showed some anatomical specimens to demonstrate the formation of the upper end of the femur and its mode of ossification. A careful investigation of these, in his opinion, explained several of the important problems associated with injuries and inflammations occurring at the hip-joint. Five specimens of the upper end of the femur were shown, forming a series at the respective ages of birth, 1 year, 2½ years, 6 years, and 13 years. He stated that at birth the upper extremity of the femur formed a single cartilaginous mass which included the head, the neck, and the greater and lesser trochanters; development of the upper end of the femur was produced

rather by a growth from the diaphysis than from the ossific centre which subsequently formed. At one year the greater part of the upper extremity was still cartilaginous, but two important changes had occurred—namely, the deposit of a small ossific centre in the caput, and an upward growth of the diaphysis into the inferior aspect of the neck. This growth during the second year separated the lesser trochanter from the upper extremity proper, and also extended into the neck, but the great mass of the extremity, including the head, the upper part of the neck, and the great trochanter, remained cartilaginous. At 2½ years the conformation had not materially altered. There had been further growth in the mass of bone arising from the diaphysis which formed the neck and some enlargement of the epiphyseal bone, but the main portion of the head was still cartilaginous, and a thick layer of cartilage on the upper aspect of the neck connected the head with the great trochanter. At 6 years there was yet no material change in the distribution of bone and cartilage. The neck had become slightly longer, the amount of bone relative to cartilage was greater, but a firm cartilaginous bar still ran from the great trochanter to the head, and it was to this connexion of cartilage that he wished to draw special attention. A dry specimen at the age of 13 years showed the bony formation of the neck complete, the cartilage of the great trochanter having been completely separated from the cartilage of the head itself; this completely surrounded the ossific centre, which had greatly extended in the meantime; at this age the articular cartilage was still continuous with the epiphyseal line of cartilage. At a later stage a differentiation of these occurred, and ultimately the epiphyseal line disappeared.

Summarizing these points, therefore, it might be concluded that at birth the whole of the upper extremity of the bone was cartilaginous, that growth of bone to form the neck originated from the diaphysis, and that a bar of cartilage connected the caput with the great trochanter up to at least the age of 10 years. A consideration of these anatomical points explained the variations in the inflammations in the neighbourhood of the joint—namely, an acute arthritis would destroy whatever portion of bone and cartilage arose from the epiphysis; on the other hand, an acute osteitis commencing in the neck would destroy the bone arising from the diaphysis but, in the early stages at all events, spared the cartilage and bone arising from the epiphysis. A series of slides was shown to illustrate these variations. In one case of acute arthritis occurring soon after birth the whole of the upper extremity corresponding to the cartilage was destroyed by acute arthritis, the patient being left subsequently with little more than the shaft and great trochanter, and a flail joint resulted. Another case of arthritis, occurring at the age of 10, showed destruction of that portion of bone arising from the epiphyseal cartilage but preservation of the neck of the bone, which at this stage was well formed and was of considerable importance to subsequent function, as it supplied a strut which, when returned to the acetabulum, supported the weight of the body. In a case of this sort comparison of the affected with the normal side showed this point clearly. Acute arthritis in the adult, on the other hand, was followed only by destruction of the articular cartilage; hence the difficulty in reducing such cases when a pathological dislocation occurred and was unreduced for any length of time. Several cases were shown of acute osteo-periostitis commencing in the diaphysis, as was usual. It was unusual for the inflammation to extend in a suppurative form from the diaphysis to the joint cavity and to find destruction of the epiphysis, whether cartilage or bone, resulting from the osteo-periostitis; hence there was no complete separation between the head of the bone which remained in the acetabulum and the great trochanter. This was exemplified by lantern slides of a patient, aged 5, who developed an acute osteo-periostitis in the upper end of the femur. Special attention was directed to the problem of slipped epiphysis in relation to the anatomical changes which occurred with age and growth in the upper end of the femur. It was common knowledge that these cases did not occur below the age of 10, and the most common time to find them was rather later than this. The speaker's explanation of this fact was that

a separation of the upper end of the femur could not occur until there had been a separation of the cartilage of the head from the cartilage of the great trochanter. Lantern slides were shown of a patient, aged 14, in whom an x-ray photograph soon after the onset of pain showed the upper end of the femur normal. Three months later the case was found to be a well marked example of slipped epiphysis, indicating that there was a pathological condition precedent to the actual slipping. Another case was shown of bilateral separation of the epiphysis in a boy, aged 14, weighing over 12 st., with undescended testes and many of the secondary female characteristics. Cases of this sort would seem to indicate that some congenital defect was associated with the slipping of the epiphysis as well as a possible inflammatory change at the epiphyseal line.

Mr. HARRY PLATT (Manchester) said that the clinical picture of uncomplicated hip-joint irritability—to use a broad, non-committal term—was familiar in the out-patient clinic. So many and so varied were the lesions which, in their earlier phases at least, gave rise to the hip-joint syndrome that Mr. Fairbank's plea for simplicity in grouping must receive their support. It would be most instructive to determine the relative incidence of the various forms of non-tuberculous coxitis as compared with proved tuberculous coxitis in the out-patient material of large clinics. There had been a tendency to envisage coxitis as a whole from the standpoint of the segregated material of the tuberculosis dispensary or county orthopaedic hospital. Sundt, the author of the classical monograph on pseudo-coxalgia, had pointed out some years ago that tuberculous arthritis of the hip was a much rarer disease than was generally taught. Broadly speaking, a persistent hip lesion in a child under 5 was likely to be tuberculous arthritis; between the ages of 5 and 10 pseudo-coxalgia was at least as common as tuberculous arthritis; while in the second decade tuberculous hip disease became a comparatively rare lesion, the characteristic affection at this age period being traumatic coxa vara. At all age periods a transitory arthritis, due, presumably, to trauma or infection, might be seen.

Tuberculous arthritis proper presented little difficulty in diagnosis in the florid phase, but there was often a long period of uncertainty in the extra-articular forms. In primary tuberculous osteitis of the femoral neck the radiographic change was often recognizable soon after the onset of persistent limp and muscular pain. In a certain number of such cases spontaneous healing of the focus might occur under appropriate conservative treatment and the integrity of the joint cavity remained unimpaired. Unfortunately, such results were by no means the rule. Primary acetabular disease was often characterized by an unusually prolonged latent clinical phase, during which the diagnosis was in considerable doubt. In a number of such cases Mr. Platt's attention had been drawn to the existence of an early clinical sign which gave a lead—namely, enlargement of the iliac glands. French writers had always stressed the importance of iliac adenitis in the syndrome of tuberculous hip disease, but in England this valuable clinical sign had been neglected, and the student was rarely taught to look for it when examining a suspected hip.

There was another small, but definite, group of hip lesions in children, which fell into the atypical tuberculous coxitis class. In these the clinical symptoms, often intermittent, were those of a mild, persistent hip disease, in which repeated radiograms showed little or no change. The clinical course was comparable with the better known arthritis sicca of the shoulder-joint. In the end absorptive changes became evident, and the diagnosis might be settled by the appearance of a cold abscess. There was always the danger, in such cases, of countermanding prematurely the regime of immobilization. In the majority of cases the radiographic appearances of pseudo-coxalgia were sufficiently typical to be diagnostic. It was not true to say, however, that in every case of pseudo-coxalgia, when first seen, the radiographic appearances were always in advance of the clinical symptoms. There was a small group of pseudo-coxalgia cases in which the first onset of definite hip symptoms was associated with little or no radiographic abnormality; in Mr. Platt's experience such atypical cases

were seen in older children, usually after the age of 10 years. The group of subacute and chronic infective synovitis and arthritis was surrounded by much obscurity. It was desirable to decide whether chronic infective arthritis of the hip arising *de novo* in children or adolescents was a definite clinical entity. From his own observations on this point he concluded that in children chronic infective arthritis of so-called primary origin did not exist as a clinical entity, though chronic arthritic changes of a destructive or hypertrophic type arose not infrequently in hip-joints which were already defective, either by reason of a mild degree of congenital subluxation or as the result of an old acute infective arthritis in early infancy. In the adolescent there were two chronic types of hip disease which might be considered to represent a primary chronic infective arthritis—namely, arthritis deformans juvenilis and dry arthritis. The clinical picture and radiographic changes of the first named were well recognized. He was formerly under the impression that this disease arose *de novo* in a normal hip-joint, but further observations had not produced conclusive evidence in favour of this view.

Mr. Platt agreed with Mr. Fairbank that arthritis deformans juvenilis represented a secondary development in an already defective hip. In the adolescent there was a definite non-tuberculous dry arthritis of the hip-joint, which ran a mild course, with moderate destructive changes leading to subluxation and ultimately ankylosis; French writers, and in particular Nové-Josseland, had long recognized this condition as a definite entity. It might be objected that it was often impossible to produce the final pathological proof that such cases were not a mild form of tuberculosis. In several hip-joints of this type, however, which the speaker had explored in order to perform arthrodesis, careful histological examination of tissues removed had failed to establish the presence of a tuberculous lesion.

Mr. ALAN H. TODD (London) stated that his proposed class of cases of "coxitis of secondary onset" was suggested as a purely clinical and practical classification; he recognized that, apart from trauma, all cases were infective, and therefore secondary, but there was obviously a vast difference between an acute fulminating suppurative arthritis at one end of the scale and a chronic infective arthritis of many years' duration at the other. It was only by grouping together the various types of cases which had well defined and similar clinical characteristics that any progress would be made with the elucidation of this disease, until the time when the complete pathology became known. Juxta-epiphyseal strain must, he thought, be the first stage of cases of ordinary "slipped epiphysis"—traumatic coxa vara. In most of these cases there was an injury in the hip region, and after a short interval the epiphysis was found, by an x-ray examination, to have slipped. Now and again a case occurred in which the hip was x-rayed and no bony abnormality was discovered, and then, a few days later, when it was again x-rayed, the epiphysis was found to be slipping or actually separate. He had heard of a case in which three successive radiograms showed at first no abnormality, then the epiphysis beginning to slip, and finally the epiphysis actually displaced. It would appear that "juxta-epiphyseal strain" would be a correct description of the clinical condition present in a case of this sort, before the actual displacement of the epiphysis had begun. As regards the sesamoid bone in the reflected head of the rectus femoris demonstrated by Mr. Fairbank, Mr. Todd thought it might be a cause of hip pain in some cases; the fact that in many cases it caused no pain was no reason why pain should not be occasioned in some. An analogy was furnished by the case of the sesamoid in the tendon of the tibialis posterior, which seemed to account for pain under the inner side of the instep in some children, since treatment directed to this cause relieved their symptoms. In addition to the definite sesamoid described, Mr. Todd had come across another abnormality in the ossification in the edge of the acetabulum, generally in boys of 15 or 16 years; the edge of the acetabulum, generally at its upper part, appeared to be fragmented, and a number of separate islets of ossification were seen. In some of these cases the

boys complained of chronic pain, and nothing else could be found to account for it, though upon x-ray examination it was often found that a similar anomaly of ossification was present in the other hip as well. As a rule the symptoms disappeared after a short period of rest, and as the boy grew older the various islets coalesced and the trouble ended.

The question of testing a suspected case of coxitis for tuberculosis had acquired a special importance in view of the fact that public bodies assumed financial responsibility for the treatment of these long and expensive cases when they were definitely diagnosed as tuberculous, but, as a rule, not otherwise. Mr. Todd had often been asked whether he was prepared to certify a given case as tuberculous, since the county medical authorities would then be prepared to provide all necessary institutional treatment, and to pay for it for several years. He feared that many were often sorely tempted to certify a doubtful case as a ready means of circumventing this unfortunate distinction. Apart from this, it was extremely important to distinguish the two classes if possible, for the non-tuberculous patients required, as a rule, a very much shorter treatment than did the tuberculous ones, so that to treat all doubtful cases as if they were tuberculous caused much unnecessary trouble to the patients and an enormous and unnecessary expenditure of public money. Mr. Todd thought that an "activation test" was a useful method of distinguishing, and quite harmless. "The patient to bed, without splints or . . . all the symptoms subsided after about two or three months he allowed the patient to walk about a little. If the case was tuberculous recrudescence of symptoms soon occurred, though the speaker had never known a case in which the disease was lit up by this test to any serious extent. On the other hand, if the case was not tuberculous, it would probably be found that the symptoms had disappeared finally, and in this way some one and three-quarter years of unnecessary splintage and expense were saved. It was necessary to record the temperature of the patient—at rest and after activity—with great accuracy: the readings should always be taken at fixed times—namely, half an hour before rising and half an hour after returning to bed. Gonorrhoeal arthritis in children was quite uncommon as a sporadic disease, but in epidemic vulvo-vaginitis, as occurring in hospital wards, it was a fairly frequent complication and usually a protracted one. Dr. Kuyvet Gordon had suggested that a histological examination of the blood should always be made in these doubtful cases. He had stated that in closed tuberculosis a blood count would almost always show leucopenia with relative lymphocytosis characteristic of a bacillary lesion, while in the infective group, usually due to coccal sepsis, leucocytosis with relative predominance of granular cells would be the rule. Mr. Todd had as yet had no opportunity of testing this suggestion, but said that only by making a collective investigation of every likely suggestion would increased knowledge of this difficult type of case be obtained. He hoped that the profession generally would not be misled into thinking that orthopaedic surgeons regarded the efficient early treatment of congenital dislocation as being other than of vital importance. The usual result of failure to reduce a dislocation was a life of absolute crippleddom, and frequently of acute suffering. Even to-day there were far too many cases in which the parents had been told that there was nothing much the matter, and that the child would grow out of it; or else that nothing could be done until the age of 10 years or so, by which time there was very little that could be done. It should be widely announced that in a case of congenital dislocation of the hip all efforts must be made to secure complete reposition of the head of the femur at an early age. In several cases in which reduction had not been effected Mr. Todd had found that treatment for some years by means of a fully weight-relieving calliper splint had resulted in satisfactory stabilization of the femur in its new position, and he was inclined to think that in the case of many delicate children this was the best treatment to adopt, for all the standard methods of fashioning a new acetabulum, by means of turning down flaps of bone, implantation of large grafts, and the like, involved a very

considerable operative shock, and were associated with formidable operative mortality.

Mr. F. C. PYBUS (Newcastle-on-Tyne) considered it important to simplify, so far as possible, the classification of the joint diseases, especially for teaching purposes; the primary division must be into tuberculous and non-tuberculous. It was also important, as suggested by Mr. Platt, to have some idea of the relative frequency of the various lesions at different age periods so that the student or practitioner might distinguish between possibilities and probabilities. It had been suggested that in pseudo-coxalgia the radiographic findings were often in advance of the clinical picture; while this was probably the commonest state of affairs, there were patients with signs and symptoms of early hip disease in which no bone change was found. Radiographic examination at a little later stage might show definite evidence of pseudo-coxalgia. Extensive bone changes might be apparent when a patient was clinically cured. He had felt some doubt as to the existence of osteo-chondritis juvenilis as a definite entity, for while the radiographic picture suggested it—by an irregularity in the bony wall of the acetabulum—this appearance was seen in normal joints, and on the sound side in some cases of unilateral pseudo-coxalgia. The greatest difficulty in diagnosis was, perhaps, in children with symptoms and signs of early hip-joint disease but without demonstrable bone or joint lesion. A period of rest for a few weeks or months might show complete resolution. After this period an examination might be made or the patient allowed exercise as a diagnostic test. There was no need to fear damage being caused by some test exercises, for, as Dr. Rollier had shown, a small degree of movement, even in tuberculous joints, was not harmful. Some years ago, when investigating the blood supply of bones, Mr. Pybus had been struck by the vascularity of the cartilaginous ends of foetal and young bones, even before the appearance of an ossific nucleus. These vessels were well seen in Mr. Irwin's specimens, and an acute arthritis of the hip in an infant represented a very unusual condition of a blood infection of hyaline cartilage.

Mr. W. A. COCHRANE (Edinburgh), referring to Mr. Irwin's account of the development of the capital epiphysis of the femur in its relation to epiphyseal separation, said that an additional point of interest in this connexion was the variation in the manner in which the capital epiphysis was set upon the neck of the femur. The line of epiphyseal cartilage might occupy the horizontal or the perpendicular plane. Mr. Cochrane thought that in the latter case epiphyseal strain and separation were more liable to occur. There might possibly be some relation between slight and neglected epiphyseal separation and the later development of cervical coxa vara. As growth proceeded, the main incidence of the bending must come to lie further and further away from the epiphyseal line, until it might finally reach its maximum in the cervico-trochanteric region of the neck. In the post-operative treatment, by drainage, of acute infective arthritis, early active movement should be encouraged. The consideration of chronic infective arthritis in regard to the removal of foci of infection was of the first importance. It had been the speaker's experience that the cases which benefited were made temporarily worse of the arthritis. With reference to pseudo-coxalgia, he did not think that it was always the case that gross x-ray changes usually preceded the onset of the clinical features. He had recently seen a patient who showed all the clinical and x-ray features of pseudo-coxalgia. It was discovered that he had been to the hospital six months previously, complaining of pain in the hip and a limp, following a fall on the hip. At that time the skiagram of the hip showed a normal appearance. Was the connexion simply a coincidence or one of cause and effect?

Mr. FAIRBANK, in reply, said he thought Mr. Daw had made a good point as to the discrepancy between the advanced x-ray changes and the duration of the symptoms in pseudo-coxalgia, but this discrepancy was by no means always present. Time must be allowed to elapse before a definite diagnosis could be arrived at in rheumatoid cases when the hips were affected first. He regarded a typical

case of rheumatoid arthritis (Still's disease) as a clinical entity with very definite signs, and he was not inclined to allow any chemical investigations to interfere, one way or the other, with his opinion. He was not prepared to accept Mr. Irwin's explanation of the fact that displacement of the head of the femur did not occur in the younger children. He thought the buffer-like action of the thick epiphyseal cartilage might be responsible, since in the femur, as in other bones, the displacement of the epiphysis usually occurred in older patients when ossification of the epiphysis was far advanced and the epiphyseal line was thin. The case of coxa vara shown by Mr. Irwin had supported his (Mr. Fairbank's) contention, as in the early radiogram shown there undoubtedly was a slight degree of displacement of the epiphysis. It was very difficult to indicate the age at which an attempt should be made to treat a pathological dislocation by arthrodesis, but he suggested 9 as the earliest age, and preferably later. In acute arthritis secondary to osteomyelitis of the femur he thought the surgeon should err on the side of opening the joint in a doubtful case. Drainage would do no harm if no tube was inserted inside the joint, and early drainage before there was any erosion would give a better result than waiting till definite changes had occurred. It had been stated that suppurative arthritis was rare in osteomyelitis. He agreed that this was so in the case of most bones and joints, but not at the upper end of the femur and the hip-joint. As to the sesamoid bone in the reflected head of the rectus, he thought there were two distinct situations in which a separate piece of bone was seen in the region of the upper acetabular lip. One, which he suggested might be the sesamoid, was near, but just inside, the upper or outer acetabular margin, while the other was outside that margin, apparently in the capsule. A woman, aged 42, showed bilateral congenital deformity of the acetabula with subluxated femora; she was suffering severely from arthritis of comparatively

recent origin. The films showed a large lump of bone on each side, apparently in the capsule above the femur. Mr. Platt's method of teaching the probable cause of arthritis at various ages would be most helpful to the student. The acetabular disease to which he (the speaker) was referring was that type in which a tuberculous deposit was present in the bone beneath the acetabular cartilage, and so was extra-articular until it perforated into the joint; it was not that form in which superficial erosion of the joint surfaces appeared to be affecting the acetabulum rather than the femur. In the slide shown by Mr. Platt he ventured to suggest, although he had not, of course, had an opportunity to examine thoroughly, that the femur showed upwards and outwards, that the case was one of primary synovial disease, with secondary erosion of the acetabulum, and was not essentially primary acetabular disease. These often showed surprisingly mild symptoms. He was glad Mr. Platt agreed with his suggestions as to arthritis deformans being secondary as a rule. He did not think the blood examination, as suggested by Mr. Todd, would be of any more use in the diagnosis of tuberculous coxitis than the Pirquet and other tests. He was afraid that they would have to treat these cases as tuberculous till the progress of time made the nature of the case clear. He had not found alteration of the plane of the epiphyseal line a cause of adolescent coxa vara. In this type his experience was that the epiphyseal line was in the normal plane.

Mr. FAIRBANK showed lantern slides of a case of acute streptococcal arthritis of the hip in a child aged 3, in which the head of the femur disappeared as a result of the suppuration, and was seen to be ossifying again seventeen months later. The shadow of the femoral head was even more obvious two and a half years after the onset of the arthritis.

## OSTEO-ARTHRITIS OF THE HIP-JOINT TREATED BY VACCINES.

(With Special Plate.)

BY

H. WARREN CROWE, D.M., B.Ch., Oxon.,  
HARROGATE.

THERE seem to be no records of any serious attempts to treat osteo-arthritis of the hip-joint by means of vaccines, and in fact medical opinion regards the disease as hopelessly incurable and progressive. It is certainly true that no medical treatment touches it—hydrology and massage are equally useless. There is often a great deal of pain, which most physicians would say was due to pressure on, or involvement of, nerve endings by bony changes in the joint.

Until a few years ago I had found myself in complete accord with these widely held views. Experience has led me to change my opinions. Osteo-arthritis of the hip-joint is not of necessity either incurable or progressive. The pain is not directly due to the bony change. The cases which follow are brought forward to prove these two contentions. Definite bony change was demonstrated by radiograms in every patient.

**Case 1.**—A labourer, aged 54, suffered for three years with pain in the left hip-joint; he was unable to sleep owing to the severity of the symptoms. Treatment by vaccines was started in November, 1925, and was continued steadily until the end of June, 1926. Although carrying on his daily work, he lost his pain and therewith his insomnia. Apart from a slight limp he now has no symptoms of any kind whatever. Of the first two radiographs, one was taken before and the other after treatment. There is hardly any difference; perhaps the bony changes are somewhat more sharply defined in the later photograph.

**Case 2.**—A woman, aged 62, had originally a fall on the right hip-joint, which was followed by intermittent pain; this had become much worse and had been very severe during the last four years. All the teeth had been removed at the age of 27. The patient was anaemic. Movement of the joint was fair, although abduction was limited and painful. This is a curious and atypical case (see Fig. 3). The disease has destroyed a probably large area of the head of the femur; operation would probably have revealed a cavity filled with granulation tissue.

Treatment was carried on for some twelve months, when all symptoms had completely disappeared. There was no limitation of movement, no pain, no limp, and function was completely restored. Fig. 4 shows, however, that the condition of the hip-joint was but little altered.

**Case 3.**—A woman, aged 62, had phlebitis eight years ago, followed by a marked limp and extreme mental depression. The right hip was adducted and slightly flexed. There was no movement of abduction and only a small degree of flexion and extension; the apparent shortening was fully one inch. Treatment was started in August, 1923, and in December the patient wrote that the depression had all gone, there was much less pain, and she was able to walk better and farther, with no pain afterwards.

**Case 4.**—A woman, aged 57, began to notice three years ago that the hip-joint was "drawing in." The pain varied in intensity, massage made it worse, and walking was intensely painful, although the joint was movable to a very fair extent. There was a most distressing limp. Treatment began in November, 1921, and was carried on intermittently for twelve months. The symptoms entirely cleared up except for a slight limp, and the patient has remained well.

**Case 5.**—A man, aged 60, had, ten years previously, felt some pain in his right hip-joint, and also in his right knee-joint. The hip is at present in a position of slight flexion and adduction, with good compensation and one inch shortening. Treatment was begun in August, 1922. In April, 1923, the apparent condition of the joint was not changed, but compensation had still further improved. He was able to lace his shoes, work in his garden, and walk several miles.

**Case 6.**—A man, aged 48, began to get stabs of pain in the right groin two years ago; this gradually extended down the leg, and, when seen, he complained of sudden sharp "turns" which nearly threw him over. He had always been an athlete. Treatment was begun in June, 1924. In August, 1925, the report was: "Played four sets of tennis and one round of golf with no ill effects."

**Case 7.**—A doctor, aged 55, had had some pain and stiffness from time to time in the left hip-joint; abduction and flexion were painful. Treatment was started in April, 1925. In October he motored twenty-five miles, played seven sets of tennis, motored back, and never felt the leg at all.

**Case 8.**—A married woman, aged 55, had felt increasing pain in her right hip-joint for the last four years. Movement was found to be very limited; slight creaking was present in the knee-joints. After treatment from August to December, 1924, the symptoms cleared up.

**Case 9.**—A woman, aged 36. This was an extremely severe case of osteo-arthritis of both hips, with eight years' history. She became much worse after a recent pregnancy. Neither leg could be adducted, with the result that in attempting to walk the feet

were always widely straddled. Pain was severe, especially at night. Treatment was begun in November, 1924, and nine months later, for the first time in two years, the right hip-joint had flexed. Now there is no pain, no discomfort, and more movement.

*Case 10.*—A very heavy man, aged 52, complained of pain in the left knee-joint, and later in the hip-joint. He limped about painfully. Treatment was begun in June, 1925; by September he was better, and in November both pain and limp had disappeared.

It is clear from these cases that after treatment the disease had not progressed, and that the symptoms had cleared up. The claim is then made good, that osteoarthritis of the hip-joint is curable, and that in successful cases patients can resume a full and active existence circumscribed only by the amount of bony changes. These are to be regarded as the results of the disease, and not as the disease itself. That the bony changes are not the cause of the pain is now obvious, for this has disappeared, although the radiographs show the condition of the joint to be unaltered.

The above cases are given as examples of very definite improvement or complete cure in osteoarthritis mainly confined to the hip-joint. Of all cases treated rather more than 50 per cent. gave similar results. Whether or no the cure is permanent time alone will show, but from experience in other forms of osteoarthritis I am confident that any relapse would quickly yield to a further course of treatment. Beyond saying that the chief vaccine used was made from streptococci obtained from foci of infection, no further details are here given, as I am shortly publishing a book on the subject, in which the methods used in this and other forms of arthritis and rheumatism are fully described.

## Memoranda:

### MEDICAL, SURGICAL, OBSTETRICAL.

#### PULMONARY EMBOLISM FOLLOWING CHILDBIRTH.

The following report of a case which I had under my care recently may be of general interest.

A woman, aged 39, gave birth to her third child; there had been very little warning of the onset of labour, and I was not present at the birth. The nurse said that she had not interfered in any way. As the placenta was a little slow in coming away I expressed it by Credé's method without vaginal manipulation. Five days later the patient complained of pain in the left thigh, and I found that many of the superficial veins were thrombosed. She then volunteered the information that she had suffered from a similar condition after the birth of her first child, and was at that time confined to bed for several months. I kept the patient in bed for a month, at the end of which time the pain had completely gone, there was no evidence of thrombosis, and she could move her leg quite freely. The temperature had been slightly raised for the first few days after the thrombosis was noticed. As a precautionary measure I kept her in bed for another week; she made rapid progress, and was soon able to get about. A fortnight after I had stopped attending, the patient developed a cough; I examined her chest carefully, but could find no evidence of anything pathological. There was no sign of thrombosis, and no complaint of pain in the legs. The next day she complained of pain on the left side of the chest under the breast, and I ordered her to bed. There was a little sputum with the cough. The symptoms suggested pleurisy; but I could find no evidence of its presence. Next day the pain was present on both sides of the chest; it was so severe that every movement caused agony. The temperature was 100° F., the pulse 85, and respirations 24; the breathing was irregular and gasping. It was difficult now to make a thorough examination, and all I could elicit was diminution in the expansion of the left side of the chest. The patient was obviously in a critical condition, and I could not determine the underlying cause. The nurse reported a slight degree of hæmoptysis, which gradually became more severe. I had the sputum examined for tubercle bacilli, with a negative result. The next development was the onset of pain in the right leg, and I found that the superficial veins were thrombosed. It came to me in a flash then that the whole trouble had arisen from the impaction in the lung of an embolus from a vein in the leg. The subsequent course of the case confirmed me in this diagnosis, and the patient is now making an excellent recovery.

Reviewing this case of a condition by no means uncommon I have come to the conclusion that I erred unwittingly in allowing the patient to get up too soon. Although all signs of thrombosis had gone I have no doubt now that the process had not completely stopped, even though there was no clinical evidence of its presence.

Cambridge.

THOS. MCCULLOCH, M.B., Ch.B.Glas.

PULMONARY embolism is such a very rare complication of childbirth that it seems scarcely ever thought of. Though Galabin gives a considerable space to it the last edition of Comyns Berkeley's *Midwifery* makes no mention of it at all. Perhaps, therefore, the following brief notes of a recent case in my practice may prove of interest.

A perfectly healthy, strong girl, aged 18, was delivered of a full-time living female child on September 6th, after an easy labour. There had been no intervention of any kind, and the baby and placenta were born before my arrival. The perineum was not torn, there was no more than the usual loss of blood, and the puerperium passed without incident. She got up, feeling perfectly well, on September 16th. The next day, about 7 p.m., she got up from her chair, picked up the baby, suddenly let it fall, fell herself to the floor, and died almost immediately.

No necropsy was performed, but I think the diagnosis of pulmonary embolism can hardly be doubted. Of all the predisposing causes given in Galabin, none were present in this case, and there was no reason to anticipate such a disaster. It would be of interest to know of any similar cases.

#### PYLORIC STENOSIS IN BROTHERS.

In August, 1923, a male infant, aged 5 weeks, weighing 7 lb., was brought to the Royal Hospital, Richmond, suffering from persistent vomiting and wasting. After keeping the child under observation for two or three days I diagnosed pyloric stenosis, and operated on August 23rd. The pylorus was constricted, rather hard, and fibrotic. The pyloric canal was a quarter of an inch in diameter. I incised the pylorus longitudinally and sewed it vertically, but unfortunately the child was so wasted that it died thirty-six hours after operation. The mother was delivered of another son in July, 1924; the second child was brought to the hospital when three weeks old, quite obviously suffering from the same condition. As there was no doubt of the diagnosis, I operated on August 5th, when the child was twenty-four days old and weighed 7½ lb.

#### Operation.

On opening the abdomen, by a mid-line incision, the stomach was so enormously dilated that it literally blew out of the abdomen like a toy balloon. So thin appeared the structure of the stomach coats that the organ was almost transparent. The pylorus itself was spindle-shaped, about one and a half inches long and three-quarters to one inch wide; it was as hard as the tendo Achillis. The pyloric aperture would admit nothing more than a large probe. It seemed useless to perform Rammstedt's operation or a pyloroplasty, as I did not see how this could cure or even relieve the obstruction; I therefore decided to perform posterior gastro-jejunostomy as the only effective remedy, although a somewhat drastic one in so young a child. The operation took thirty-five minutes. Tincture of belladonna (1 minim) was given every four hours for a few days. The child vomited occasionally, but eventually made a good recovery. The weight increased by 2 or 3 ounces weekly during the three months it was in hospital. Subsequently the child has been admitted for slight vomiting attacks, which seemed to be due to some error in feeding. At the last visit to the hospital the stomach was x-rayed, and was seen on the screen to be acting perfectly. The patient is now 2 years old, well developed, and in every way a fine child.

#### HERPES AND VARICELLA.

The following case is of interest in connexion with the alleged relation between herpes and varicella.

On March 21st my wife developed a very severe attack of unilateral herpes, affecting the neck and shoulder, which kept her in bed for a month. On April 5th my son, aged 9 years, was taken ill with chicken-pox, which ran a typical course. No outside source of infection could be traced.

## STRANGULATED HERNIA IN AN INFANT.

THE memorandum on strangulated hernia in infancy by Dr. Buckley in the JOURNAL of September 18th (p. 525) recalls a similar case I had recently.

A male child (full time) was born with a right inguinal hernia which was easily reduced. The mother consulted me when the child was 19 days old because she could not get the swelling back as usual, and the child was continually crying. I failed to reduce the hernia with gentle manipulation, posture, etc. Later in the day I tried again, unsuccessfully, with light chloroform anaesthesia. By this time the swelling had become tense and tender, the pulse was rapid, and the temperature  $99^{\circ}$ , so I decided to operate in hospital. Under chloroform I opened up the sac, which contained dark fluid and about four inches of small intestine, barely viable. I divided the stricture, replaced the loop of bowel, and did a radical cure as quickly as possible. The skin wound was closed with Michel's clips, and no dressing was applied except daily dusting with pulv. acid. bor.; healed by first intention. The child was kept on the breast and made an uneventful recovery.

## Reports of Societies.

## ANATOMICAL FACTORS IN URINARY INFECTIONS.

MR. W. GIRLING BALL read his presidential address at the meeting of the Section of Urology of the Royal Society of Medicine, at the society's house, on October 28th. The subject of his address was "Some anatomical factors in urinary infections."

In opening the subject, Mr. Girling Ball referred to the presumption that in all cases of urinary infection the presence of some pre-existing abnormality should be considered. Admitting that these were not always demonstrable, certain cases in which a long-standing diagnosis of pyelitis had been made were referred to and the existence of such factors was demonstrated. Recent experiments seemed to show that bacteria did not pass through a normal kidney and cause a persistent infection unless some causative factor existed. The speaker considered that it was not clear that irregularities of the action of the bowel were always present in cases of urinary infection, and pointed out how difficult it was to define an actual lesion of the intestine in these cases. He suggested that some obstructive lesion of the urinary tract, or some contact lesion between it and the intestinal tract, was more commonly present than might be anticipated. To support this, records were given of obstructive lesions of the urinary tract to show how commonly these were associated with urinary infections. It was also shown that the bacterial flora of the intestine were the most common micro-organisms of infection. A review was then made of intestinal diseases which were associated with urinary infections, including those associated with appendicitis, diverticulitis, intestinal fistulae, malignant growths of the intestine, and salpingitis, and the following conclusions were arrived at—namely: that adhesion and anatomical proximity of inflammatory lesions of the intestinal tract and pelvic viscera, although not common, occurred more frequently than was generally recognized; that although these lesions did occur, the symptoms of urinary diseases with the absence of urinary lesions occurred much more frequently. Many urinary infections of the chronic type might be dependent upon intestinal lesions which were adherent to some part of the urinary tract for considerable periods before the actual condition of affairs was shown by an acute flare-up of such a lesion; and it might be that more chronic infections of the urinary tract were due to this cause than was generally recognized. Although the haematogenous infection of the urinary tract was the course at present most generally recognized, it must not be assumed that this was the only method of infection; neither should it be considered that, in the event of contact between the two tracts, the direct infection was dependent upon this contact, for in some cases the adhesions between the two were responsible for obstruction to the urinary passages, which rendered the renal pelvis a suitable site for a haematogenous infection.

## COMPARATIVE MEDICINE.

THE first meeting of the session of the Comparative Medicine Section of the Royal Society of Medicine was held on October 27th, with the President, Sir D'ARCY POWER, in the chair. Before reading his presidential address, the President paid a warm tribute to the late Sir William Leishman, the president-elect of the Section, and a resolution of sympathy with Lady Leishman was passed in silence.

Sir D'Arcy Power then read his presidential address. Mindful of his own limitations, he said, and acting on the advice of Apelles the Athenian, that a shoemaker ought not to criticize outside his trade, he had decided to speak about those who might have qualified for election to honorary membership of the Section of Comparative Medicine, and so give some idea of the origin of the Section. Like a river, medicine had a common source in natural history; it divided into two streams of human and veterinary medicine—both empirical—and reunited to form comparative medicine, which it was the business of the Section to maintain and to place on a scientific footing. The first to be considered as president, that was if he was not elected patron, would be Hippocrates, whose keen intellect recognized that the diseases of man and animals were very closely allied. Aristotle, the "Master of all who know," would at once have joined and have taught us much that was long forgotten and was only now being re-discovered. The first candidate for honorary membership, however, would undoubtedly be Mago, the Carthaginian, the "Father of agriculture," whose twenty-eight volumes on the subject had been translated into Latin and Greek. Xenophon, who had a very real and a very modern interest in horses, would have been a member, and so also would have been Vegetius, who was far in advance of his time, and who, ridiculing the idea of disease being evidence of divine wrath, advised the deep burying of dead animals. Pliny, who took all knowledge for his province, would also have been a member, and with him would have joined Celsus, a writer about whom it was still disputed whether he was practising physician, veterinary surgeon, or merely a literary Roman gentleman with scientific aspirations.

Leaving the ancients, Conrad Gesner, whose *Historiae Animalium* dealt at large with the diseases and habits of animals, would surely have been admitted. The next on the list would have been Gervase Markham, who, however, might have been blackballed, for Sir Frederick Smith said of him, that he knew nothing of his subject, and was not only a mean plagiarist, but a violently untruthful person! Robert Lovell would certainly have been admitted because of his *Compleat History of Animals and Minerals*, even though his book was a mere restatement of the learning of classical times and might well have been written in the Bodleian. John Hunter would surely have been elected first president had his times been ripe for inaugurating the Section, and he would as certainly have enlisted the assistance of Astley Cooper, the elder Cline, William Simmons, Edward Jenner, and Munro secundus, while Sainbel, the first principal of the veterinary college in London, would at least have attended the meetings. In our own times, Parker and his great expositor, Thomas Huxley, would have been members.

It thus came about that, by a gradual process of development, a society for the study of comparative pathology became possible. The Section owed much to Clifford Allbutt and Sims Woodhead, who wished to start such a society at Cambridge many years ago. However, no active spirit had come forward then, and it was not until the veterinary side of the profession became active that the Section became possible—possible also in a wider sense than had been originally planned, for it became comparative medicine instead of comparative pathology. The experiment was proving a great success. The work embraced a vast field, extending on the one side to the most difficult problems of human medicine, and on the other to the interrelation of human and veterinary medicine, showing thereby that the processes of disease, whether in man or in animals, were identical. Its world, too, touched the confines

of tropical medicine—the most virile, the most progressive, and the most valuable of all branches of medicine to a country with a great colonial empire. For this reason a discussion had been arranged between that Section and the Tropical Diseases Section on trypanosomiasis, a subject which the late Sir William Leishman had made peculiarly his own.

Sir ARBUTHNOT LANE joined with the president in paying tribute to Sir William Leishman, and looked to a great future for the Section of Comparative Medicine.

### TUBERCULOSIS IN YOUNG GIRLS.

A MEETING of the Manchester Medico-Chirurgical and Obstetric Society was held on October 13th, when a short address was read from the President (Sir THOMAS BARLOW) and Dr. N. C. HARING read a paper on the treatment of tuberculosis in young girls.

Dr. Haring said that he had little belief in any of the new and much advertised cures for consumption, but he was hopeful that something would result from the recent work of Professor Calmette of Paris, whose work was known all over the world, and whose laboratory was above reproach. As a result of many years of patient investigation in this country it had been stated that there were very few children who did not have some infection with the tubercle bacillus. It was possible that if the risk was not too great it might be beneficial for all children to be infected with tuberculosis in a mild form so that they might be spared the horrors of consumption in its ordinary and severe forms. Neither medicine nor surgery had done very much to cure consumption. When tuberculosis was cured it was more often cured by natural processes than by the treatment of the medical man who attended the case. It was true that abdominal tuberculosis was sometimes much improved by a simple laparotomy; it was also true that a broken down tuberculous gland in the neck required an operation, but on the whole the efforts of the surgeon were uncertain in their results. Fresh air, good food, cod-liver oil and malt, iron, and other tonics were the stand-by. The treatment by artificial pneumothorax was of undoubted value when only one lung was affected. The value of x rays in the diagnosis of tuberculous disease of the lungs was uncertain. If the result of the photograph was positive it was most useful, but if the plate showed no disease it was not certain that all was well. X rays were very useful in diagnosing enlargement of the mediastinal glands, and sometimes would show up abdominal tuberculosis, but not always. He urged practitioners to investigate every case of anaemia very closely, for he was convinced that the old type of chlorosis was rarely seen in these days, while the anaemia of consumption was becoming more and more common.

Dr. G. CHESNEY asked if it was worth while boiling the milk for young children if it was better for them to begin life with a mild attack of tuberculous infection.

Dr. LOUISE ARONOVITCH asked if it was safe to diagnose tubercle by a deficiency in the breath sounds combined with an x-ray photograph showing a slight abnormality in shaded areas.

Dr. J. C. ATHERLEY asked how it was that some children had developed tuberculosis under apparently the most perfect conditions possible and without any hereditary taint or tendency.

Dr. HARING, in reply, said that all milk should be boiled, since no one could guarantee a mild infection. Diagnosis of tubercle based on deficient entry of air into the chest was unsafe. How exactly tuberculosis was caught was a matter for discussion, but the bacilli were ubiquitous, and infection was therefore possible everywhere, and under any conditions.

A prolonged discussion followed on the various methods of treatment which had been recommended.

### WEST KENT MEDICO-CHIRURGICAL SOCIETY.

THE seventy-first annual meeting of the West Kent Medico-Chirurgical Society was held at the Miller General Hospital, Greenwich, on October 8th, when Dr. H. Nockolds

was elected president and Dr. C. J. B. Buchan honorary secretary. In the course of the clinical part of the meeting Mr. C. A. JOLL showed cases illustrating abdominal surgery in women aged 58 and over. His cases included perforated gastric ulcer in a bilocular stomach, of which seven-eighths was removed by operation; gastric ulcer associated with chronic duodenal ulcer and gall stones; columnar-celled carcinoma of the ascending colon; caecostomy; cholecystectomy; and removal of the rectum by the abdomino-perineal route in a woman aged 62, who had mitral stenosis. Mr. P. B. RORN showed a girl, aged 9, with a crushed sixth cervical vertebra due to a cycle accident; torticollis had been produced at first, but was cured by massage. He showed also a girl with overgrowth of the radius in both forearms, involving considerable deformity but no loss of power, and a man with muscular wasting of the right hand, due to pressure on the brachial plexus from his having been accustomed to carry heavy planks of wood on his shoulders. Dr. H. NOCKOLDS showed a boy with pseudo-hypertrophic muscular atrophy, and a woman, aged 59, who had not been abroad, but who had had elephantiasis of the right leg since the age of 19.

### JAMES MACKENZIE INSTITUTE FOR CLINICAL RESEARCH, ST. ANDREWS.

#### High Blood Pressure.

ON October 19th Sir HUMPHRY ROLLESTON, Bt., M.D., read a paper on high blood pressure from the clinical aspect. The question particularly raised was whether or not a rise of blood pressure *per se*, apart from causal toxic factors or the resulting arterio-sclerosis, gives rise to symptoms of ill health. It was not an uncommon experience to detect blood pressure readings higher than the average in individuals who are entirely free from symptoms, and harm might result from too energetic measures adopted for lowering these pressures. Certain hypersensitive subjects, however, might conceivably manifest symptoms as the result of the heightened blood pressure alone. Libman had described a simple means of estimating the individual's response to afferent stimuli, and attributed angina sine dolore to the patient being hyposensitive. But to apply this explanation to high blood pressure would necessitate the assumption that in the early stages persons with high blood pressure were hyposensitive and became hypersensitive; possibly as high blood pressure was often due to protein derivatives, the hypertensive individual's nervous system might at some stage become sensitized by the protein bodies and so allow symptoms due solely to the high blood pressure to appear. On the other hand, some—for example, F. M. Allen—considered that high blood pressure was always due to underlying structural changes either of the kidney or of an arterio-sclerotic nature. Bordley and Baker showed by *post-mortem* findings that arteriolar sclerosis in the medulla oblongata was definitely associated with high blood pressure. But it was difficult to believe that such a change could underlie those cases in which a high pressure persists for years with no advance and without interference with health. The possibility of arterial spasm was also referred to in this connexion. Much interesting work done by Draper on the constitutional make-up of subjects of high blood pressure was mentioned. Finally the lecturer considered seriatim the various symptoms commonly associated with high pressure cases in their early stages and questioned whether or not these occurred in the absence of definite chemical or structural changes. The tendency to haemorrhage (epistaxis, intestinal, retinal, cerebral, etc.) was probably dependent, not on the pressure alone, but on vascular degeneration associated with it. Each common symptom was considered separately, and it was shown that probably each could be explained by the presence of some factor other than the rise of pressure.

In the paper and the discussion which followed it the importance of the distinction between the rise of pressure itself and the associated degenerative changes was emphasized.

## Reviews.

### A TREATISE ON SOCIAL HYGIENE.

THE first volume of a German handbook of social hygiene and the care of health,<sup>1</sup> edited by GOTTSTEIN, SCHLOSSMANN, and TELEKY, suggests a subject for discussion—namely, whether there really is any advantage in such joint undertakings over independent ventures; any advantage, we mean, from the point of view of the student. Such textbooks as Osler's *Medicine*, the material of which has been moulded by a single intellect, are wholes; they bear the stamp of one personality. This is less true, even of so carefully edited a work as Allbutt and Rolleston's *System of Medicine*, and not true at all of the new French treatise on medicine, the forty fascicules of which will really constitute a medical encyclopaedia without alphabetical arrangement. The scale upon which the book before us is planned—the first volume contains 511 large pages, and five more volumes are announced—ranges it with the encyclopaedic class. Ventures of this kind are more often undertaken in France and Germany than in England. Were they chiefly of German origin we might perhaps explain it by supposing that the more docile German student is glad to be saved the trouble of choosing an "authority" for himself. But actually French works on this scale are almost as numerous. Perhaps the only strong argument in favour of the method is that an expert who has it in him to write a good treatise may be more readily induced to take part in a co-operative work than to publish independently. If we compare French and German treatises it is usually said, and truly said, that the former are better written but the latter take more heed of work done outside the writer's own country. The explanation of the undoubted superiority of French books over German treatises in the art of writing is not, we think, any inherent superiority of French over German as an instrument of precision—Heine's prose illustrates how beautifully German can be written—but the fact, noted in Mr. Flexner's recent study of medical education in Europe, that Frenchmen are made to take pains to write French, while Germans have very little more respect for their mother tongue than most of us have for ours.

The first article in this *Handbuch* is by Hueppe; it affords a good illustration of what has been said. Many sentences must be read more than once by a foreigner moderately well acquainted with German before he grasps the meaning, and with one sentence we have succeeded in puzzling a German. Some of the facts—the article is an account of the history of social hygiene—will be new to most readers, but the whole produces no clear impression. The second article, on statistical methods, by Weinberg, is much more satisfactory; it is a clearly written account covering a good deal of ground and using no more mathematics than is indispensable. It would not have been human if the author had not given rather more space to his own work than the impartial critic might think it needed. But as this work, particularly with reference to the fallacies of selection and how to avoid them, is really important, it is well that it should be clearly described. Weinberg was one of the first statisticians to maintain that Karl Pearson's demonstration of a greater liability of first-born children to various abnormalities was fallacious, a position subsequently taken up by Yule and Greenwood in this country. Pearson replied to their arguments in 1914, and, as generally happens, all the parties to the discussion remain of their original opinions. Weinberg puts his side of the case quite clearly. The next article, by Prinzing, is a short but quite satisfactory account of the principal data of medical statistics. The essay which follows is by Valentin Haecker on heredity. It is fully documented and quite easy reading, for the author eschews the technicalities of modern Mendelism, which are almost as provocative of headaches as even skew variation and multiple regression.

The longest section is devoted to tuberculosis, and the

<sup>1</sup> *Handbuch der Sozialen Hygiene und Gesundheitsfürsorge*. Herausgegeben von A. Gottstein, A. Schlossmann, und L. Teleky. Erster Band: Von Hygiene und Methoden. Berlin: Julius Springer. 1925. (Sup. roy. 8vo, Pt. 1: xi + 511. G.M. 30; bound, G.M. 35.)

conclusion to which it leads the reviewer is that, in spite of all that has been done and written in the last twenty-five years, we really know practically nothing of importance about the constitutional factors, if any, of tuberculosis, so that both those who proclaim that there is no problem of inheritance in tuberculosis and those who assert that an inheritance of soil is almost everything and variations of exposure to infection of trifling importance are merely darkening counsel. Indeed, the whole modern history of opinion upon the general etiology of tuberculosis is somewhat humiliating, for, without any real additions to our stock of positive knowledge, there have been violent changes of fashion in opinion. Clinicians, biometricians, biologists, and economists have never hesitated to form (and publish) conclusions which not one of them had really sufficient knowledge to enable him to test.

The next chapter, by the late Professor Martin, on school anthropometry, is chiefly descriptive of technique and seems to be exhaustive. Martin Vogel deals with popular education in hygiene and includes a useful summary of methods employed in other countries; he is very appreciative of Sir George Newman's memorandum on public education in health. This article is long, but it covers a wide field. Grotjahn's account of the education of the medical student shows that, at least in some German universities, hygiene as a branch of the ordinary curriculum is more seriously considered than in this country. Both in Munich and Berlin it would appear that there is a much better provision for the instruction of such students and graduates as wish to learn than we shall have in London until the new School of Hygiene opens its doors. The programme of the department of social hygiene at Berlin originally formed in the Hygienic Institute of the university by Flüge is very attractive. The seminar system is undoubtedly far more satisfactory for real students than being lectured at even by eloquent lecturers.

The remaining sections, by Dietrich and Krautwig, on organization of health measures, are rather more interesting to German physicians and hygienists than to foreigners, but will be of value to those of us who wish for detailed information respecting present German law and practice.

On the whole we should say that this is a sound treatise. It has no literary charm, but, with one exception, the articles are clearly written, and all are, we think, technically adequate. For some time to come it will be a useful work of reference.

### PSYCHOTHERAPY.

*Psychotherapy*,<sup>2</sup> by DR. EDWARD WYLLYS TAYLOR, James Jackson Putnam Professor of Neurology in Harvard University, is one of the volumes of the "Harvard Health Talks." The book is the substance of a lecture given at the Harvard Club, and in a compact form the writer has managed to convey an eminently readable account of the treatment of disease by mental means from the beginnings of communal life to the present day.

At the conclusion of his lecture Dr. Taylor expresses the view that the future of psychotherapy, halting as its progress has been, is now assured. He points out, however, that if this mode of treatment is to advance along rational lines it must remain essentially in the hands of the medical profession, from which, so he believes, it already shows signs of passing. It would be regrettable if this were to happen, since in view of the wide incidence of mental disorder in the community it is essential that the medical practitioner should be in a position to apply psychotherapeutic methods where they are indicated, and to this end, as Dr. Taylor observes, subjects dealing with the mind should be given equal importance with those dealing with the body in the pre-medical as well as in the medical course. Unfortunately, as far as this country is concerned, insufficient attention is still given to mental disorders and their treatment in the medical curriculum, though the creation of out-patient clinics for psychiatric cases in the majority of teaching hospitals has done something to remedy this deficiency.

<sup>2</sup> *Psychotherapy: Mental Elements in the Treatment of Disease*. By Edward Wyllys Taylor. Harvard Health Talks, 14. Cambridge: Harvard University Press; London: H. Milford, Oxford University Press. 1926. (Fcap. 8vo, pp. 53. 4s. 6d. net.)

## RECENT PHYSIOLOGY.

It is not surprising that Professor LOVATT EVANS's *Recent Advances in Physiology*,<sup>3</sup> which was reviewed in these columns on January 9th last (p. 57), has so rapidly passed into a second edition. The preface to the first edition is dated August, 1925, but since then more recent advances have necessitated additions to what the author modestly but appropriately calls "an elementary textbook of advanced physiology." Thus the work of C. R. Harington on thyroxin, and of Best, Dale, Hoet, and Marks on insulin, have rendered obsolete what was so recently believed. J. J. Abel's isolation of insulin in a crystalline form is mentioned; and it is considered that if it is a peptide, two of the most likely component amino-acids are histidine and cysteine. Other additions and alterations have been made—for example, attention is directed to Anrep and Segall's experimental work, which modifies Marey's law so that now in addition to a reflex from the heart through the vagi the influence of raised blood pressure on the cardio-inhibitory centre must be taken into account in the production of the slowing of the pulse rate as the result of a rise in blood pressure. The section on muscular contraction has been expanded, and in the interesting account of the capillary circulation Florey and Carleton's contention that the motor activities are due to the endothelial elements of the capillaries, and not to Rouget's cells, is mentioned.

That a work of this kind is essential to a scientific physician who wishes to keep in touch with the ever-advancing and shifting knowledge of the fundamental science of physiology cannot be questioned.

## MAKING TERMS WITH TUBERCLE.

A popular book such as *Diseases of Animals in Relation to Man*,<sup>4</sup> just added to the series of "Modern Health Books" edited by Professor D. FRASER HARRIS, was wanted, and he is to be congratulated on the writer he selected. It would have been easy to turn out a couple of hundred small pages of rhetoric and error, mingled with abuse of persons concerned with the preservation of the public health. Instead the choice fell on Dr. T. W. M. CAMERON of the London School of Hygiene and Tropical Medicine, who knows the subject from A to Z, understands the relative importance of things, and has the command of a simple clear style. He begins with two chapters on tuberculosis, and a better presentation of the present position of the subject is not anywhere to be found. Dr. Cameron is a veterinary practitioner, but thoroughly understands the problem on the human side, and does not hesitate frankly to explain how much the best pathological and epidemiological opinion has changed during the last few years. After describing bovine tuberculosis and its relation to human, he has the courage to write, "The more widely spread tuberculosis is in a community, the smaller is the case mortality," and to quote with approval the dictum of an Italian worker, "Where there is much tuberculosis in animals, there is little in men." The argument is that, if we were successful in completely eradicating tuberculosis from man and animal in Britain we should be a highly susceptible race, and in order that the future tubercle-free generation should be safe it would be necessary to achieve this "throughout the whole world, or else prevent communication with all other lands where tuberculosis exists." Dr. Cameron's conclusion is that our efforts towards eradicating the disease as a cause of death must be directed to "our being thoroughly, and completely, and benignly tubercularized." Everyone will not be prepared to accept this view, but the author at any rate leaves us in no doubt about his opinion, to which much weight must be attached.

The chapter on rabies is excellent, well informed, and temperate; the same is true of the next, on small-pox and cow-pox. Then come short accounts of various diseases common to, or supposed, sometimes erroneously, to be common to, man and animals, a chapter on milk which is

a model of condensation and good sense, and another on meat poisoning, short but good.

Dr. Cameron has produced an excellent book, one which members of public health authorities ought all to study, and one which should be in the offices of newspapers that do not wish to be swept away by every wind of sensationalism.

THE EARLY HISTORY AND ANTIQUITIES OF  
MACEDONIA, THRACE, AND ILLYRIA.

Those who served during the war with the Salonika Army, the Army of the Black Sea, and on the Gallipoli Peninsula (the Thracian Chersonese), and who take an interest in the antiquities and ancient history of the areas over which military operations were conducted, will read with pleasure a book that has been published recently on Macedonia, Thrace, and Illyria in their relations to Greece from the earliest times down to the time of Philip of Macedon, son of Amyntas III and father of Alexander the Great.<sup>5</sup> The author, STANLEY CASSON, is university lecturer in classical archaeology at Oxford, and was sometime assistant director of the British School at Athens. It will be remembered that representatives of the school were attached to the Salonika Army during the war, and that antiquities unearthed during digging of trenches and other military constructions were carefully collected by them. Mr. Casson had visited Salonika in 1913 and 1914, and during the war, between March, 1916, and December, 1918, saw most of Macedonia from the Vardar to the Struma. Subsequently, down to April, 1919, he was in Constantinople, and became acquainted with the country round the Bosphorus, and in later years journeyed throughout Macedonia and Thrace, the Gallipoli Peninsula, Dalmatia, and Montenegro.

In the first part of his volume he gives an account of the geography of Macedonia and Thrace, their natural resources, especially the mining industries, known to the ancients, and the grouping of their cities. There are interesting descriptions and illustrations of those well known features in the country round Salonika, the Macedonian tumuli, and of the antiquities found in excavations and caves in the Balkans. Several of the "finds" were collected by the British Salonika Force in 1915-16, and were presented by the Greek Government to the British Museum after the armistice. Illustrations and descriptions of some prehistoric Thracian weapons, including the *Máxapa*, which is not unlike some of the weapons which could be seen in the Salonika bazaars, and a list of sites where excavations have been made, are appended to a chapter on prehistoric periods. Chapters on the kings and chieftains of Macedonia and Thrace, on the Thracian Chersonese, and on art during the sixth to the fourth century B.C., are full of interesting and scholarly historical research. Appendices to Part I of the volume contain a map and description of Ainos, the modern Enos, at the mouth of the Maritza. Ainos was an important seaport for the trade of Thrace and of the districts beyond Adrianople as far as the Black Sea. An underground church there is regarded by Mr. Casson to have been in ancient times a shrine for the worship of Pan, a form of worship unusual among the Thracians. Another appendix indicates the sources available for the study of the earlier history of Thrace and Macedonia.

Part II of the volume is a brief description of the ancient roads, antiquities, and Greek settlements in Illyria, the territory between Serbia and the Adriatic. The evidence regarding ancient times is meagre, and it was of minor importance in early history; but, according to the author, its story is indisputably bound up with that of Macedonia.

A list of the museums where collections of North Aegean antiquities are to be seen is given in the preface; and at the end of the volume there is a numbered list of finds of the Neolithic, Bronze and Copper, and Iron Ages, with corresponding numbers plotted on a map, showing the places where each was found. The volume also contains an extensive bibliography, and a list of British and foreign maps of the areas with which it deals.

<sup>4</sup> *Diseases of Animals in Relation to Man*. By Thomas W. M. Cameron, M.A., B.Sc., Ph.D., M.R.C.V.S. London: Faber and Gwyer, Ltd., the Scientific Press. 1926. (Fcap 8vo, pp. 222; 13 figures. 3s. 6d. net.)

<sup>5</sup> *Macedonia, Thrace, and Illyria: Their relations to Greece from the earliest times down to the time of Philip, son of Amyntas*. By Stanley Casson, M.A. London: H. Milford, Oxford University Press. 1926. (Med 8vo, pp. xxi + 357; 106 plates, 19 maps. 21s. net.)

The main portion of the book is founded on an essay awarded the Connington Prize for 1924, and its purpose is to set forth the chief evidence available for the reconstruction of the earlier history of the North Aegean coastline and its hinterland. The volume is illustrated by excellent photographs, some of them reproducing beautiful views of places in the Near East.

### THE SIGMOIDOSCOPE.

THE small book on the endoscopy of the rectum and colon by Dr. BENSANDE, a second edition<sup>6</sup> of which has just reached us, contains a very complete description of the sigmoidoscope and its use in the differential diagnosis of diseases of the rectum and colon. Valuable practical hints on the choice of instruments, the preparation of the patient, and the technique of examination are followed by a well illustrated account of the normal appearances of the bowel at different levels.

The diseases of the rectum are dealt with on a plan which comprises a good description of the pathological anatomy of each morbid condition, illustrated by numerous black-and-white drawings, and the sigmoidoscopic appearances are then shown in a series of colour plates which most successfully and faithfully reproduce what is actually seen. A special feature of the colour plates, which are certainly above the average both in execution and variety, is the polyglot description attached to each of them, for no fewer than six European languages are employed to explain each picture; French naturally takes pride of place, with English second, followed by Italian, German, Spanish, and Portuguese.

### NOTES ON BOOKS.

THE medical practitioner at home, whether he has lived abroad or not, is frequently asked for his opinion and advice by those who are proceeding to the Colonies either for a trip or to take up some appointment. The absence of any small work dealing with the numerous points involved has led to the promulgation of all sorts of information, some of it fantastic, much of it erroneous, a little of it correct. Dr. BALFOUR KIRK's book of *Hints on Equipment and Health*<sup>7</sup> fulfils to a nicety the requirements of the European about to venture trade abroad. It is small and inexpensive, and, though not intended strictly for medical men, will be read by them with advantage. It consists of a series of letters, giving just the kind of information which the layman wants and needs. With the exception of a few points on first aid, medical matters, *sensu stricto*, are rightly left alone. One of the greatest bores, and the most noxious which it is the lot of most professional men to encounter, is the layman with a smattering of so-called medical knowledge. Here we have a common-sense view of the dangers of tropical residence and of the means of forestalling them; advice as regards vaccination against small-pox and the enterica group prior to sailing; recommendations as to outfit, both for children and adults, and the domestic medicine chest. The questions of personal hygiene, diet, and drink, its use and abuse, exercise, recreation and fatigue, the advantages of an agreeable hobby, and the need for rest—all are dealt with. Sanitation, including not only personal hygiene, but also domestic matters which have to be supervised by the European if his house is to be comfortable and himself and his belongings kept free from disease—such matters, for instance, as cleanliness of quarters, mosquito-proofing of rooms, mosquito nets, the taking of quinine, disposal of refuse, exclusion of flies, and so on—all receive attention, adequate but not too elaborate. The letters are written in a vein of sound common sense, with witty turns of expression, and the advice given is such as will be strongly endorsed by everyone who, by hard-won personal experience of life in tropical countries, has learned the lessons which are here conveyed so clearly. The author is to be congratulated on the success with which he has performed his undertaking; the book should, and probably will, become part of the equipment of each intending traveller to the tropics. We can only wonder at the space it will occupy having been so long unfulfilled.

<sup>6</sup> *Traité d'Endoscopie Recto-Colique: Rectoscopie Sigmoidoscopique*. Par Dr. R. Bensande. Deuxième édition. Paris: Masson et Cie. 1926. (Imp. Soc. pp. 187; 115 figures in the text, 93 figures on 25 plates. 120 fr.)

<sup>7</sup> *Hints on Equipment and Health for Intending Residents in the Tropics*. By J. Balfour Kirk, M.B., Ch.B.Ed., D.P.H.Oxon., D.T.M., and M.C.I.C. London: Baillière, Tindall and Cox. 1926. (42 x 7, pp. vii + 120. 6s. 6d. net.)

The fasciculus on the genus *Amblyomma* forms the first part of the second volume of NUTTALL, WARBURTON, and ROBINSON's monograph on the ticks.<sup>8</sup> Although not so rich in species parasitic in man as some of its congeners, the genus *Amblyomma* is the largest in point of numbers of the genera of ticks. It contains four species which have been recorded from human beings. One of these species is a carrier of Rocky Mountain spotted fever, and another has been described as "the greatest pest to man" in Jamaica. Many of the species are parasitic on mammals—including the vector of "heartwater"—but the range of hosts is large, although, curiously enough, no species has been recorded from birds. Geographically also the range is large, although, excepting a single species in Spain, none have been found in Europe. This part, written by Dr. L. E. Robinson, maintains the high standard set in previous parts of the monograph. It is well illustrated—there are in the text over 130 excellently drawn figures, of which 120 are original. Each of the 86 species is described in detail. There is an extensive host-list, a bibliography, an index, and an appendix on the biology of the genus. Dr. Robinson has contributed an immense amount of labour and patience to the making of this part of the monograph, and he has rendered yeoman service to a branch of entomology in which there is much still to learn. He has made available for entomologists throughout the world a volume which has long been awaited, and which, for once, proves that realization may be better than anticipation.

The book on radium treatment of cancer,<sup>9</sup> by Dr. SIMONE LABORDE, director of the Radium Laboratory at the Anticancer Centre at Villejuif, consists of four parts. In the first the author discusses the physical properties of radio-active substances in general and those of radium in particular. The second part serves as an introduction to the study of cancer, including its clinical aspects and diagnosis by laboratory methods. In the third part a description is given of the sensitiveness of healthy and neoplastic tissues respectively to radium. The fourth part, which forms the bulk of the volume, deals with the technique of the radium treatment of the various localizations of cancer. The last two chapters are devoted to the complications observed during radium therapy and the accidents that may be caused by the manipulation of radio-active substances, with the precautions to be taken to avoid them. An extensive bibliography is appended. The book, which is essentially practical, will not only appeal to the specialist, but will furnish the general practitioner with a valuable guide to the study of the radium treatment of malignant disease.

The publishers of Wheatley's authoritative edition of the Diary of Samuel Pepys have now issued in one volume an abridgement of the complete copyright text, with the title *Everybody's Pepys*.<sup>10</sup> The abridgement has been judiciously carried out by Mr. O. F. MORSHEAD with an eye to the tastes and interests of the ordinary reader. The printing is excellent, and the volume is adorned with a large number of cheerful illustrations by Mr. Ernest H. Shepard, whose delicate humour in black and white is well known to readers of *Punch*. The insides of the back and front covers are appropriately decorated with maps of London in the sixteen-sixties, showing the districts east and west of Whitefriars, and the River Thames from Whitehall to Richmond, and eastwards by London Bridge. A jollier gift book it would be hard to find.

<sup>8</sup> *The Genus Amblyomma*. By L. E. Robinson, Ph.D.Cantab., A.R.C.So. Lond. Being Part IV commencing Vol. II of Ticks: A Monograph of the Ixodoidea. By George H. F. Nuttall, F.R.S., C. Warburton, and L. E. Robinson. London: Cambridge University Press; London: H. K. Lewis and Co., Ltd. 1926. (Cr. 4to, pp. xii + 302; 8 plates, 130 figures. 20s. net.)

<sup>9</sup> *La Curiothérapie des cancers*. By Simone Laborde. Paris: Masson et Cie. 1925. (Med. 8vo, pp. xi + 333; 43 figures. 27 fr.)

<sup>10</sup> *Everybody's Pepys: The Diary of Samuel Pepys, 1660-1669*. Abridged from the Complete Copyright Text and edited by O. F. Morshead. London: G. Bell and Sons. 1926. (Cr. 8vo, pp. xxiv + 570; 60 illustrations. 10s. 6d. net.)

### PREPARATIONS AND APPLIANCES.

#### Zorbo Joint Jackets.

MESSRS. ROBERT BAILEY AND SON, Ltd., of Marriott Street Mills, Stockport, and Sentinel House, Southampton Row, W.C.1, manufacture a dressing for joints entitled "Zorbo joint jackets." The dressing consists of a shaped pad of cotton-wool in a gauze covering, to which are attached tape straps and small buckles. The pad can be impregnated with lotion or liniment prescribed by the doctor, and is easily applied by the patient to the affected joint. It is claimed that the pad is useful in the treatment of sciatica and rheumatism; and there is no doubt that the shaping of the pad renders evenness of application easy. The joint jackets are made in six shapes: for the chest, the shoulder, the elbow, the wrist, the knee, and the groin.

## THE SIGNIFICANCE OF ANATOMY.

THOMAS VICARY, M.D., F.R.C.S., to four English sovereigns and to four times Master of the Company of Barbers and Surgeons of London, would hardly have appreciated the lecture delivered in his memory by Professor Elliot Smith, of which we publish a report in the opening pages of this issue. The lecturer, with becoming candour, declined to flatter the eponym of the endowment under the auspices of which he spoke, but admitted that Vicary was even behind his own times and his book a mere plagiarism of the authors whose works had been discredited by the new knowledge of Vesalius. We venture to think that he would also have been puzzled by the views set by the lecturer before his audience. In some ways Professor Elliot Smith's lecture may be taken as an elaboration of the theme upon which Sir John Rose Bradford spoke so well and wisely in his Harveian Oration, for he makes—although not in so many words—a well supported claim upon medicine as a debtor to anatomy. If we adopt the lecturer's view that anatomy includes physiology, morphology, and morbid anatomy, and that morphology is the foundation of all science, then indeed the claim may be considered to be triumphantly established, and morphology should be enthroned in the highest place of the scientific Olympus, instead of being, as he complains, depreciated by physiologists, clinicians, and biologists, and even by some anatomists.

It is right and proper that a distinguished man of science, such as Professor Elliot Smith, should be enthusiastic in magnifying the importance of those branches of knowledge with which he has been and is so conspicuously concerned, and the opinions he has expressed deserve the closest attention and study and the deepest respect. Many who are not specialists in descriptive anatomy are apt to regard it as an indispensable but unprogressive branch of knowledge—a valuable and standardized tool of the physician, and still more of the surgeon, which has reached such a degree of perfection, as compared with other departments of medical study, that little further change is likely to be made in it. But to Professor Elliot Smith it is almost infinitely greater than this. More than thirty centuries before Aristotle, he says, the study of mankind (and in particular the phenomena of life and death) was the sole aim of all science and art, and no innate curiosity exists in mankind to study the forces of nature except in so far as they affect his own obvious interests, so that the moon was only watched on account of its apparent connexion with the reproductive system of the female, as shown in the periodicity of the observed phenomena. Yet it might be supposed that to dwellers near the sea or the estuaries of great rivers the phenomena of the tides, and the synchronism of springs and neaps with the phases of the moon, must early have excited a curiosity quite unconnected with any questions of human life and fate. Whatever may have been the case in Egypt, where the study of the viscera seems to have had so great an importance, we venture to

think that many anthropologists will hesitate to admit that, in other and more primitive civilizations, considerations less anthropocentric had not their influence, and that it is too much to claim that "civilization was evolved out of man's endeavours to understand the constitution of his own body and to preserve the life that animated it." Self-preservation was doubtless the moving power in all primitive communities, but magic, which played such a great part in the beliefs and life of the savage, was surely concerned at least as much with the phenomena of outside nature as with the real or supposed construction of his body. Our knowledge of Egyptian civilization, of which we owe so much to Professor Elliot Smith, goes back a long way, but who can doubt that between the Neolithic culture and such an advanced organization as the Egypt of five millenniums ago there must have been many successive cultures that have been wiped out and have left no intelligible message for us? In what manner and from what point of view each of them envisaged the eternal problem of how and why and whither, we know not.

If some of the opinions expressed by Professor Elliot Smith invite criticism, there can be no doubt of the value of his remonstrance against any neglect of morphology as an aid to investigation, in which it ought to go hand in hand with physiology. He wisely cautions us against putting our trust so greatly in experiment as to neglect the evidence that can be given by the study of form in organisms of all sorts and the lessons that may be learnt by the comparison of a whole series of homologous parts from the simplest to the most complex known to us. In the great physiological collection in the Museum at Lincoln's Inn Fields comparative anatomy has many lessons to teach to those who can and will learn them. Function is of the greatest importance to the physiologist and anatomist.

Perhaps not the least interesting portion of the lecture was the historical sketch of the part played by anatomy (using the word in Professor Elliot Smith's widest sense) in the history of medicine and surgery. Harvey was primarily an anatomist. Sharpey, who invented the modern methods of practical physiology, insisted on retaining microscopical anatomy as part of that subject, and so, as Professor Elliot Smith maintains, crippled anatomical research, by depriving anatomy of the use of the experimental method and separating the investigators of structure from those of function. The brilliancy and extent of John Hunter's work has prevented a due appreciation of that of his great brother William, and their remarkable joint work on the lymphatic system has not had the appreciation it deserves. Charles Darwin based his own work on comparative anatomy, and himself wrote that morphology is the soul of natural history.

Even now questions as to the sympathetic system and the existence in man of differentiated muscle fibres, and their innervation, are the subjects of discussion and difference of opinion between physiologists and surgeons. Still more anatomical studies are necessary before the truth can be ascertained. Many other instances of the need of anatomical investigation were given by the lecturer, whose hopes of future progress are neither faint nor faltering. His appeal to the Council of the Royal College of Surgeons to modify the primary examination for the Fellowship in the direction of demanding a greater knowledge of comparative anatomy and morphology will be received with mixed feelings by those unfortunates who are

preparing for that *peine forte et dure*, unless it is to be understood that a corresponding relaxation on the side of descriptive human anatomy is to be its accompaniment.

### POOR LAW REFORM.

ALMOST a year ago the Ministry of Health circulated to associations of local authorities, to county councils, county boroughs, and others concerned, the proposals for Poor Law reform which were to be incorporated forthwith in a bill.<sup>1</sup> It will be recalled that the Government proposed, among other things, to abolish boards of guardians and transfer their functions to county and county borough councils. But from one cause and another the Ministerial programme was disturbed, and, as recorded last week in our parliamentary notes, the Minister of Health does not now hope to obtain this autumn even a preliminary debate in the House of Commons on the bill he is preparing. It is anticipated, however, that Mr. Chamberlain will shortly issue a draft or summary of the bill for examination by politicians and public authorities, and there is still some expectation that the Government will make this bill a principal item of legislation next year. In the meanwhile it is of interest to note that the provisional proposals of the Minister have been accepted by the London County Council, subject to certain amendments called for by the special conditions obtaining in the metropolis. A report was made to the Council on November 2nd by a special committee, under the chairmanship of Sir Cyril Cobb, M.P., which was appointed in December last to explore the situation.

The Minister's proposals for London involve the abolition of boards of guardians and of the Metropolitan Asylums Board, with the transfer of their functions, institutions, and staff to the London County Council, and the central supervision, through the Council, of the administration of these services. There are in London twenty-five boards of guardians, which control about 140 institutions, including 30 hospitals and infirmaries; and the Metropolitan Asylums Board has about 60 institutions, including 17 infectious diseases hospitals, 10 institutions for tuberculosis, and 7 mental hospitals. The committee considers that the proposals, while not entirely in accord with the principles approved by the Council as a basis for Poor Law reform, should be welcomed as an earnest attempt to deal with a difficult and controversial problem. Under the Minister's scheme the Council will be the ultimate authority in questions of relief, including domiciliary medical relief, and it will undertake complete responsibility for all forms of institutional treatment, all the work relating to pauper lunatics and the mentally deficient at present dealt with by the guardians, and the services of the Metropolitan Asylums Board. One of the declared objects of the scheme is the co-ordination and improvement of the provision for the prevention and treatment of ill health, both institutional and other, and the inclusion in such provision of public assistance which may be required as the result of sickness, accident, or infirmity. With a view to achieving this object it is proposed that the powers of the London County Council shall be strengthened to enable it to undertake the general oversight of all health services throughout the county, as well as the duty of acting in place of a metropolitan borough council in default of any of these services. This proposal is con-

sistent with a scheme which was submitted to the Council some time ago by a special committee on health administration, which desired to see the Council the central organizing authority with the responsibility of preparing surveys of health services from time to time. The responsibility for the distribution of local grants in aid of health services will also devolve upon the Council.

The report presented to the London County Council on Tuesday last stated also that it may be necessary for the Council to be enlarged in order to cope with this transferred work, and that in any case there should be provision (as, indeed, the Minister forecasts) to enable the Council to avail itself by co-option of the services of suitable persons from outside its own body, on some of the committees upon which the duties will devolve. There is provision also for the delegation by the Council to the metropolitan borough councils (twenty-eight in number) and the Common Council of the City of London of any transferred service identical in kind with a service already administered by those bodies. The committee is uncertain what services other than maternity and child welfare would fall within this definition. The care of the health of Poor Law children attending school, for instance, could not be delegated, and the committee suggests that the definition should be widened to include similar or ancillary as well as identical services. The scheme also provides that the functions of guardians under the Vaccination Acts shall be vested in the Council, but the committee points out that vaccination is a service extraneous to the general work of public assistance, and thinks that this service should be transferred direct to the borough councils. The registration of births, deaths, and marriages will, under the Minister's proposal, be transferred to electoral division officers acting for metropolitan boroughs. There is a consensus of opinion on the committee that the administration of outdoor relief, or "home assistance," should be a function of the borough councils, the London County Council to be responsible for matters of policy and finance concerning the county as a whole and for the laying down of general principles and rules, including the scale of relief, but delegating to the borough councils the duty of administering such assistance and any ancillary functions in their areas. The Council would appoint an advisory committee, called a Public Assistance Committee, consisting of members of its own body with a number of persons from outside having experience in such work, and each of the local councils would appoint a similar committee.

The London County Council agreed to a resolution authorizing its special committee to enter into negotiations with the Minister of Health, with the Common Council of the City of London, and with the metropolitan borough councils, with a view to the amendment of the Minister's scheme generally on the lines indicated in the report. The matter is one of considerable importance, direct and indirect, to the medical profession, and the outcome of these negotiations, and also of those which must take place between other big public authorities and the Minister, will be awaited with interest. The attitude of the British Medical Association towards certain features in the Government's proposals was discussed briefly in our issue of June 19th last (p. 1048), and a month later the subject was debated further at considerable length by the Representative Body at Nottingham, as recorded in the SUPPLEMENT of July 31st. Since April a special committee of the Association has been watching the position in regard to reform of the Poor Law.

<sup>1</sup> BRITISH MEDICAL JOURNAL, December 12th, 1925, p. 1136.

## THE BEIT MEMORIAL FELLOWSHIPS.

WE mentioned last week that the trustees of the Beit Memorial Fellowships for Medical Research are about to appoint a Fellow to devote his whole time to research in tropical medicine, and an advertisement of the terms and conditions will be found elsewhere in this issue. The fellowships were founded and endowed in December, 1909, by Sir Otto Beit, as a memorial to his brother Mr. Alfred Beit, to promote the advancement by research of medicine and the allied sciences in their relation to medicine. The general policy for the administration of the foundation was settled by a board of trustees, which consisted of men of affairs and representatives of medicine and the allied sciences. The trustees act under the guidance of an advisory board consisting of Dr. William Bulloch, F.R.S., Professor T. R. Elliott, F.R.S., Sir James K. Fowler, K.C.V.O., M.D., Sir F. Gowland Hopkins, F.R.S., Dr. C. J. Martin, F.R.S., Sir Charles S. Sherrington, G.B.E., M.D., F.R.S., and Professor E. H. Starling, M.D., F.R.S. There have hitherto been three classes of fellowships—junior fellowships of £350 a year, usually held for three years; fourth year fellowships of £400 a year, to which a junior Fellow may be appointed; and senior fellowships of £600 a year, usually held for three years. A senior Fellow must have been first elected to the junior fellowship on or after January 1st, 1920. The election of Fellows takes place in July, and applications from candidates must be received on or before the first day of June preceding the election. The fellowships are open to persons of European descent without restriction as to nationality. All the facts necessary to be known by a candidate are set out in the book of regulations, which can be obtained from the honorary secretary, Sir James K. Fowler, 35, Clarges Street, London, W.1. To the new issue of this book has been added for the first time an account of the after-histories of those who have held a fellowship since the foundation in 1910. During the four years of the war very few appointments were made, and nearly all the Fellows resigned to undertake war work of more immediate importance. The real purpose of the trust is to help young men and women who show promise of being capable of doing good research work in their early fertile years, before, as is almost inevitable, they settle down in teaching appointments and become involved in administrative duties. The list of Fellows shows how widely the trustees have cast their net and some of the big fish they have caught. The first name is that of Sir Thomas Lewis, F.R.S., who held a fellowship from 1910 to 1913 for the study of irregularities of the heart. The second is that of G. C. McKay Mathison, M.D., Melbourne, who was investigating the nervous control of respiration; he died in 1915 of wounds received at Gallipoli. Another name on this page is that of Dr. Sidney Russ, professor of physics, Middlesex Hospital Medical School, who was appointed in 1910 to study the association of radio-activity with cancer, a subject to which he has since made many valuable contributions. Two other names early on the list are those of Dr. Edward Mellanby, now professor of pharmacology in the University of Sheffield, and of Dr. T. R. Elliott, F.R.S., professor of medicine in the University of London and head of the Medical Unit of University College Hospital, who in 1911 was appointed to make researches into the pathological changes in the suprarenal glands. The first woman's name to appear is that of Miss Ida Smedley (now Mrs. Hugh Maclean), who was a Fellow for four years and investigated the processes involved in the formation of fat in the organism. The names of many other well known workers are contained in the list; it already possesses historical interest, which will be greatly increased as time goes on if the list is maintained, as is to be expected, from year to year. It may be added that

in its selection of Fellows in the past the trustees have not failed to encourage the study of tropical medicine; for instance, one of the first Fellows was Dr. Hindle, who was appointed to investigate the morphology and treatment of protozoic blood parasites, and there have been a good many other appointments since. The new appointment of a special fellowship in tropical medicine will be made for five years, and the salary will be £1,000 a year; in addition passage money out and home, if the research is conducted in the tropics, will be paid, and a grant will be made for laboratory expenses. Applications for this tropical fellowship must be received by the Honorary Secretary on or before February 1st next, but candidates resident in Australia and New Zealand can obtain a form of application from the registrar of their university.

## BACTERIAL ENDOCARDITIS.

THE war was responsible for many infections, and among them chronic bacterial endocarditis, also called endocarditis lenta, which came more prominently into notice, and has been specially studied by Lewis, Cotton, Horder, H. J. Starling, and others in this country. Before the war Osler and Libman in America were foremost in defining its clinical and pathological features. As has been already mentioned in our columns (1926, i, 749) in connexion with Sir Thomas Horder's Lumleian Lectures on endocarditis, Professor W. S. Thayer<sup>1</sup> has recently published an elaborate monograph on bacterial (infective) endocarditis, and analysed 362 cases of acute and subacute endocarditis examined after death at the Johns Hopkins Hospital during the thirty-four years and a half ending on January 1st, 1924. Bacteriological examinations were made before or after death, or both, in 241, or 66.6 per cent., and the nature of the bacterial infection was determined in 130, or 36 per cent., of the total 362 cases, streptococci heading the list with 60, *Staphylococcus aureus* and the pneumococcus with 26 each coming next; the gonococcus with 19 was the only other micro-organism in double figures. A table of 212 cases obtained by combining the figures given by Harbitz, Lenhartz, Horder, and Clawson shows the streptococcus in 62 per cent., the pneumococcus in 17 per cent., the *Staphylococcus aureus* in 14 per cent., and the gonococcus in 3 per cent. The relatively large number of gonococcal cases in the Baltimore series is explained by the inclusion of negroes, among whom venereal disease is very common, and by the keen look-out for thirty years for gonococcal endocarditis at the Johns Hopkins Hospital. The much debated question of the relation of rheumatic endocarditis to recognized bacterial endocarditis is carefully considered, and, while it is admitted that rheumatic endocarditis may in the future be proved to be bacterial, the following data are laid down as necessary before a case can be labelled rheumatic: negative cultures from the blood during life or from the blood and heart lesions after death, and a clinical history of rheumatism or chorea. Aschoff's focal perivascular bodies, which are considered to be characteristic of acute rheumatism, were present in six cases yielding streptococci; for this and other reasons the total number of cases of fatal rheumatic endocarditis was reduced from 43 to only 24; but it is remarkable that fatal cases have lately become less rare than in the earlier years of this hospital's records. The bacterial forms of endocarditis are considered separately; the Baltimore statistics are compared with those from other sources, and valuable summaries given; thus pneumococcal endocarditis contrasts with the rheumatic in occurring later in life, after pneumonia, accompanied by high leucocytosis, frequent embolic phenomena, and in nearly a quarter of the cases by acute

<sup>1</sup> Johns Hopkins Hospital Reports, Baltimore, 1926, xxii, Fasciculus I.

nephritis; previous cardiac disease is uncommon, the infection appears to be uniformly fatal, and acute suppurative meningitis the usual termination. Gonococcal endocarditis, which in many respects resembles the pneumococcal, is less acute in its course, a third of the cases lasting more than two months, and a case of recovery after four months' illness is recorded; it has a special tendency to attack the aortic and pulmonary orifices and the aortic intima. Of the streptococcal cases the acute—namely, under a month's duration—were ascribed to undifferentiated forms in nearly 80 per cent., whereas in the subacute cases—namely, over a month's duration—*Streptococcus viridans* was the infective agent in over 80 per cent. Enough has perhaps been said to show the minute character of the analysis of the pathological data; the clinical features are considered in similar detail, and there can be no doubt that Professor Thayer's monograph will long remain a valuable storehouse for reference.

#### RESEARCH IN GENERAL PRACTICE.

THE claims of clinical medicine to be ranked as a science have lately been ventilated in our pages and elsewhere, and we think that we have shown cause why they should be granted. The fact must not be lost sight of, however, that the great mass of clinical work in this country is done by general practitioners, who, unfortunately, for various reasons are not able to take advantage of the opportunities that offer themselves for advancing medical science. Deficient equipment is no doubt one reason, but very much more often the cause is to be sought in the engrossing and multifarious duties which take up the time and exhaust the energies of the men and women engaged in general practice. The matter has been raised once more in a thoughtful article by Dr. M. Forrester-Brown,<sup>1</sup> in which, after mentioning the nature and vast amount of the material available and the difficulties in the way of its fruitful study, she takes as an example of the good that may be done the schemes for the care and cure of cripples which have been brought into being, first in Shropshire and since in other counties and districts. The distinguishing feature of these schemes is continuity of treatment through co-operation between general practitioners and specialists; a serious attempt is being made to ensure that every case shall be detected at the earliest possible moment and be properly looked after from the first sign of disease until its cessation. Although it is no doubt true that many of the cases treated under such schemes differ in their age and their tendency to spontaneous cure from other categories of disease among the general population, it is suggested that by a somewhat similar organization similar benefits might be secured in those other categories. The great advances in medicine and surgery in late years have made it impossible for any one practitioner to be efficient and up to date in all branches, and increased division of labour seems to be desirable and indeed inevitable. This necessity has already been recognized in various quarters, and the custom of a medical firm including among its members one who specializes in surgery, another in ophthalmology, and perhaps another in cardiology, is, as we are informed, on the increase. Radical changes in the relations between the doctor and those numerous patients who still, like their savage ancestors, look upon him as a dealer in magic, whose spells are conveyed in mixture, lotion, powder, or pill, must come slowly; but it is to be hoped that the younger generations are more wholesomely sceptical and will in time welcome co-operation in medicine as well as in industry. The doctor in populous districts will have, on his part, to train himself to be much more of a specialist than he is at present, and to achieve this

recourse would have to be made to post-graduate instruction, a good deal of which might be imparted in local clinics. Dr. Forrester-Brown thinks that the more brilliant practitioners should have the chance of appointment to the teaching staffs of the medical schools, so that some at least of the instruction in his life's work would be given to the student by those who had had personal experience of such work, as was the case under the old system of apprenticeship whenever the master was willing and able to instruct. But since the chief complaint is that neither the earliest beginnings of disease nor the real end-results of treatment are now adequately known and recorded, it seems that teaching of the kind suggested must be given outside the great teaching hospitals, which devote—and, as far as we can foresee, must always devote—their attention to what may for convenience be called acute cases. If this be true it follows that there will be no place for the general practitioner on the staffs of the medical schools. His work and his teaching must be done elsewhere by utilizing the material which only exists outside the walls of the educational hospitals. Dr. Forrester-Brown does not claim to have solved the problem which she set before her readers, but her suggestions seem worthy of consideration and discussion out of which something of practical value may come. Of the soundness of the view that organization, co-operation, specialization, and division of labour are needed in general practice there is not much doubt.

#### AMBROISE PARÉ AS NATURALIST.

DR. PAUL DELAUNAY, the well known medical historian of Le Mans, has devoted an erudite monograph<sup>1</sup> to the attention paid by the father of French surgery to the various branches of natural history, including zoology, parasitology, toxicology, and teratology. It may be said at once that Ambroise Paré was merely an amateur naturalist, and that his knowledge of natural history was based, not so much on the direct observation of nature, as on a study of the early Greek and Latin writers, such as Aristotle, Pliny, and Aelian—and even these only at second hand in translations, and on the often distorted descriptions given by travellers of hitherto unknown animals in the recently discovered continents of India and America. Dr. Delaunay points out that Paré had the misfortune to live at a time when science was only escaping from the toils of scholasticism to become the slave of antiquity again. Among other errors Paré shared the belief of Aristotle and Pliny in the spontaneous generation of certain animals, such as spiders, scorpions, worms, frogs, toads, and such-like. Moreover, Paré's observations on natural history, to the study of which he was drawn by his instinctive curiosity, laboured under three disadvantages characteristic of the time—namely, the absence of a rational classification, an exact nomenclature, and an accurate iconography. Except for one or two designs, all the illustrations in Paré's book had been borrowed from other works, and were either delineations of purely imaginary monsters or inexact representations of animals which really existed. The only problem on which Paré appears to have exercised his critical faculty was that of the existence of the unicorn, his conclusion being that but for the authority of Scripture he could not believe that such animals existed. In his description of monsters, to which he devoted the whole of his twentieth book, Paré attributed their origin partly to the wrath of God or the work of demons. He admitted, however, that natural development might be disturbed by purely material causes, such as inherited disease, weakness of the sperm, narrowness of the womb, or injury from without. In forming a just estimate of Paré's contributions to natural history it must be borne in mind that

<sup>1</sup> *Practitioner*, September, 1926.

<sup>1</sup> *Ambroise Paré Naturaliste*, Laval, 1926.

it was not until the time of Bacon, followed by Descartes, and later still the encyclopaedists, that natural science became free from the influence of authority and the occult, and became based solely on experience.

### THE MISSION TO LEPERS.

THE origin and growth of the Mission to Lepers are ably and modestly described in an account of fifty years' work between 1874 and 1924, published at the price of one shilling by the mission's London office (33, Henrietta Street, London, W.C.1). The movement commenced in 1869, when Mr. Wellesley Bailey joined the American mission in Ambala in the Punjab, and came in contact with lepers in the leper asylum there. Through the influence of his wife, Miss Grahame of Blackrock, Dublin, whom he married in 1871, he enlisted the sympathies of three sisters, the Misses Pim of Monkstown, one of whom, Miss Charlotte Pim, in 1874 promised to give or try to collect £30 annually in aid of his work in Ambala. At the end of the first year between £500 and £600 had been received, and with this sum a mission to lepers in India was definitely established. The funds increased year by year, and in 1905, after thirty-one years of development and with an income then of £21,005, leper settlements had been organized throughout India, Burma, Ceylon, and the Far East, chiefly in connexion with missionary stations of every religious denomination. In that year the number of the mission's leper settlements or aided settlements was 63, with 5,803 leper inmates and 317 untainted children, who were kept in separate compounds and brought up and educated by the mission's workers. During the next eleven years governments and local authorities co-operated in the work, and a great advance was made; in the remaining eight of the fifty years covered by the report much was done in developing the curative methods of treatment suggested by the researches of Sir Leonard Rogers and others. Some idea of the vast field of work in which the mission is labouring may be gathered from the fact that in the census of India for 1921 as many as 102,513 definite cases of leprosy are recorded, that in China alone the number of lepers is estimated to be 400,000, and that throughout the world there are between two and three million lepers. The improvement that has been effected by the mission in the conditions under which this vast suffering population, originally social outcasts and without hope, are living is inestimable. It is one of the finest examples of world-wide philanthropy that has been achieved in the last half-century. In connexion with the jubilee celebrations in London in 1924 of the Mission to Lepers, a deputation was sent from England to examine the existing conditions in various countries with a view to the extension of the work. The report of this deputation has now been published under the title of *Dawn and Gleam*, by W. H. P. and M. Anderson, which may also be obtained from the mission's London office for 1s. 3d. The report is fully illustrated, and contains a very interesting account of the work in progress in India, China, and Korea. Dr. Robert G. Cochrane, who accompanied the deputation to India, has now published a final report on the medical work of the Mission to Lepers in India, including Burma, which is similarly obtainable. Dr. Cochrane suggests that leprosy hospitals should be organized in future along the lines of a tuberculosis sanatorium, where hopeful cases alone would be admitted. In each province there should be one such hospital with a full-time physician as well as a medical superintendent. A good dispensary and a hospital for medical cases would also be required, and the asylums for chronic lepers would be co-ordinated in the whole scheme, which would involve the appointment of an additional six or seven full-time medical practitioners. Training would be given to medical practitioners and students in the

diagnosis and prevention of this disease, and propaganda work be organized among the general public. In a preliminary note it is stated that the council of the mission has accepted the suggested scheme, and, without making any change in the present general character of its work, will endeavour to give effect to the recommendations as rapidly as circumstances and the resources of the mission may permit.

### DICK PROPHYLAXIS OF SCARLET FEVER.

THE Dick prophylaxis of scarlet fever has now attained a considerable vogue on the North American continent. In the United States, alike in family practice and in the conduct of residential institutions, it is pretty extensively used. It is applied to children in schools, and also, by certain public health officers, to the general child population of areas. In Canada during 1925 the Provincial Board of Health of Ontario co-operated with the executives of several homes or reformatories to produce immunity in their inmates, and scarlet fever toxin figures have been issued in the returns of the provincial laboratories for that year. An account by Professor James Miller of procedure for the immunization of a Canadian city has been published (July) by the *Public Health Journal*, the organ of the Canadian Public Health Association. The city of Kingston, Ontario, which has 23,000 inhabitants, had during the four years ending March, 1925, been afflicted by a prevalence of scarlet fever which rose during each winter season to some 30 cases or more a month, and declined, but without disappearing, in summer. The notification of 38 cases in February, 1925, roused the authorities to action. Arrangements were made to apply the Dick method of prophylaxis, and in March, 1925, it was offered gratis to all comers. Some 1,200 persons, including both children and adults, were treated. Notifications at once began to fall off and continued low. For the first time in the four years since the outbreak began there was no winter rise. From January to May of 1926 the average case rate was less than four a month. At this point the record ends for the present. While the number of persons treated was small and the dosage employed is admitted to have been inadequate, it cannot be denied that a change ensued when the procedure was adopted; but, in the absence of information as to the ages of the persons concerned, the distribution of cases subsequently occurring as between the protected and the unprotected, and similar points, it is difficult to be sure of its causes. A coincidental factor such as spontaneous decline might possibly have been at work. The effort, however, was well devised, and the figures as they stand, if not entirely convincing, are of interest and value as a contribution to the study of scarlet fever prophylaxis.

### PUBLIC HEALTH IN GERMANY.

PROFESSOR ABEL, director of the Jena University Hygiene Institute, lately gave two lectures in London for the Chadwick Trustees on the development and present state of public health in Germany. The German Ambassador was present at the first lecture, and thanked the Chadwick Trustees. Professor Abel compared the origin and administration of public health work in the two countries. In England, owing to the earlier date of the industrial revolution and the consequent crowding into towns, the need of modern hygiene manifested itself before it did in Germany. English public health, in its origin, was inspired by ideas of humanitarianism and economy; German public health was born in the chemical and physical laboratory. The first hygiene institute was founded in a German university in 1865, but the active development of practical hygiene occurred after 1871; in Germany at the present day nearly 67 millions are living on an area almost as large as France, which only supports a population of 40 millions. In 1871

only 32 per cent. of the population was urban, in 1925 as much as 64.35 per cent. Professor Abel explained that there were few Reichs laws (laws applying to the whole of the empire), and no Public Health Act comparable with the English Public Health Act of 1875. The Ministry of the Interior is in the last resort responsible for the public health; in Prussia there is a Ministry of Public Welfare with a physician at its head; in other States the chief official is a lawyer. There are about 1,000 full-time medical health officers (Kreisärzte), all of whom are paid by the State; they do also all forensic medical work. In addition a fair number of large administrative units have appointed and are paying medical welfare officers, whose duties are largely clinical; they examine school children, attend maternity and child welfare, tuberculosis, and venereal disease centres. One of the subjects of examination in State medicine is psychiatry. There are no sanitary inspectors in Germany. The Imperial Health Office was founded in 1876 to assist the Ministry. There is now an advisory committee as well; and similar bodies exist in many of the States, but some are not much consulted. A census is taken every five years. In 1871 the crude death rates, which alone were available, were considerably higher in Germany than in England, but in 1925 the German rate was below that of England. The birth rate in Germany had declined greatly, especially in towns, but the decrease was beginning to be experienced in rural areas. He considered that deliberate limitation of the number of children was being practised for economic reasons. In Germany the last figures showed that the population had diminished in a year by half a million. To alter this better economic conditions must be secured for the working classes so as to enable them to afford to have children. This loss of population made eugenic considerations all the more important; people about to be married ought to avail themselves of the facilities for the official medical examinations now available in most of the German States. The group of infectious diseases caused one quarter of the deaths; the vaccination of babies and revaccination of children at 12 against small-pox was compulsory; although it had been proposed to recognize the "conscientious objector," the central position of Germany in the European continent, and its consequent liability to infection from all sides, would make this a more serious experiment than in other countries. Of the relatively few cases of small-pox which occurred in Germany, foreigners constituted a large proportion. Whereas Germany, with its vaccination laws, had 57 cases in the last three years, England had 11,630. No fees are paid to doctors and midwives for the compulsory notifications, which are generally required to be sent to the police. Tuberculosis, venereal disease, and alcoholism had been called the three national scourges of Germany; tuberculosis caused every seventh death. In addition to open-air and forest schools much sanatorium accommodation was provided for children; the advanced cases, so largely responsible for infection, are sent into hospital. There is no general obligation to notify tuberculosis; in Prussia, for example, only open pulmonary and laryngeal cases are notifiable to the medical officer of health. For venereal disease there is compulsory medical treatment, and penalties can be enforced against anyone knowingly spreading such disease. The consumption of alcohol is less than before the war, and the State gives subsidies to temperance societies; but a prohibition law is not now possible. The growing devotion to sport, Professor Abel thought, would diminish the desire for alcohol and tobacco.

We regret to have to record the death, on November 2nd, of Professor Francis Mitchell Caird of Edinburgh. He graduated in 1877, and was professor of clinical surgery in the University from 1908 to 1919.

## Nova et Vetera.

### A CASE REPORT BY RHAZES.

THE following clinical notes from one of the best known works of the old Arabian physician Razi is of interest as showing how the ancient medical men were confronted with the same bedside problems as we are at the present day, and solved them by much the same process as to-day, although the assistance of modern instruments such as the microscope was lacking.

Abu Bakr Muhammed ibn Zakariyya of Ray, known as Razi or Rhazes, was one of the greatest of all the Muslim physicians, and wrote a large number of works; one of the most interesting, as containing so much clinical matter, is the *Hawi*, or "Continens."

Rhazes did not start his medical career till he was of mature age. He attended the hospital at Ray, near Teheran, in Persia, and ultimately became chief physician to it. Later he became head of the hospital at Baghdad, an institution which he himself founded. There is a legend that when asked to select a site for the building he hung up pieces of meat in various parts of the town, and chose the place where the least decomposition had taken place. The dates of his birth and death are not accurately known, but the latter event took place about 900 A.D.

The following is a translation by the late Dr. E. G. Browne, Professor of Arabic in the University of Cambridge, of one of the cases recorded by Rhazes:

"Abdulla ibn Sawada used to suffer from attacks of mixed fever, sometimes quotidian, sometimes tertian, sometimes quartan, and sometimes recurring once in six days. These attacks were preceded by a slight rigor, and micturition was very frequent. I gave it as my opinion that either these accessions of fever would turn into quartan, or that there was ulceration of the kidneys. Only a short while elapsed ere the patient passed pus in his urine. I thereupon informed him that these feverish attacks would not recur, and so it was.

"The only thing which prevented me at first from giving it as my definite opinion that the patient was suffering from ulceration of the kidneys was that he had previously suffered from tertian and other mixed types of fever, and this to some extent confirmed my suspicion that this mixed fever might be from inflammatory processes which would tend to become quartan when they waxed longer.

"Moreover, the patient did not complain to me that his loins felt like a weight depending from him when he stood up; and I neglected to ask him about this. The frequent micturition also should have strengthened my suspicion of ulceration of the kidneys, but I did not know that his father suffered from weakness of the bladder and was subject to this complaint, and it used likewise to come upon him when it was healthy, and it ought not to be the case henceforth, to the end of his life, if God will.

"So when he passed the pus I administered to him diuretics until the urine became free from pus, after which I treated him with *terra sigillata*, *Boswellia thurifera*, and Dragon's blood, and his sickness departed from him and he was quickly and completely cured in about two months. That the ulceration was slight was indicated to me by the fact that he did not complain to me first of weight in his loins. After he had passed pus, however, I enquired of him whether he had experienced this symptom, and he replied in the affirmative. Had the ulceration been extensive, he would of his own accord have complained of this symptom. And that the pus was evacuated quickly indicated a limited ulceration. The other physicians whom he consulted besides myself, however, did not understand the case at all, even after the patient had passed pus in his urine."

This case presents an interesting diagnostic problem: was it an attack of malaria or of pyelitis? The reasoning of Rhazes would do credit to a modern medical man. The final opinion of Rhazes is probably one which often enters the mind of many of us, but, it is to be hoped, is expressed a little less bluntly.

## CHRONIC RHEUMATISM.

### CONFERENCE IN AMSTERDAM.

By invitation of the Dutch Committee of the International Society of Medical Hydrology a conference on rheumatism took place at Amsterdam on October 23rd. The guests from England represented the Ministry of Health, the British Committee on Rheumatism, the British Red Cross Society, the British spas, and the British Spa Federation.

The morning was spent at the Instituto for Physical Treatment, where the medical director, Dr. VAN BREEMEN, who is also secretary of the Dutch Committee, demonstrated the various methods of treatment by which heat, cold, light, electricity, and manipulation were applied in rheumatic and circulatory disorders. Among these methods were the Winternitz friction bath and hot-air chambers, the steam douche and radiation, followed in each case by immediate manipulation. As many as 300 patients from insurance societies were sometimes treated in one day.

The party were entertained by the Committee to luncheon, after which a public conference on chronic rheumatic diseases took place at the Colonial Institute, about 900 persons being present, Professor TROUB, Chairman of the Dutch Committee, presiding. Letters were received from the Chairman of the German Committee, and from representatives of France, Denmark, Belgium, Sweden, and Austria. Statistics of the incidence of rheumatic diseases were being prepared in Vienna and a special conference was arranged.

The Minister of Labour, Professor SLOTEMAKER DE BRUINE, as chief of the Department of Public Health, officially welcomed the guests. He was glad that Holland should have a good place in this work. He hoped that in Holland statistics of the incidence of rheumatism might be prepared, similar to those published by the British Ministry of Health. The Dutch Government had every desire to support this movement.

Professor TROUB said that the neglect of the study of common rheumatic disorders, and the absence of clear data, was bad alike for the patient and for the community. In Holland there were large numbers of workers suffering from rheumatic invalidity, and he was glad that the press was interesting itself in the question. Dr. van Breemen was the medical consultant to the new Dutch Committee, and they hoped to establish a special hospital for rheumatism in Amsterdam at an early date. These diseases affected the nation as a whole, and a national effort was needed to combat them.

Dr. FORRESTUE FOX said that, visiting the health resorts of many countries, he had become convinced of two things: that their age-long popularity was justified, for modern medical observation had only confirmed the universal experience of the value of external treatment by baths and internal treatment by waters in chronic rheumatic affections; and that these natural physical remedies, if they were to be used with any advantage in our present civilized life, must be given by practitioners of special training and experience. The effects of baths, in particular, must be watched by the eye of the physician from day to day; even more than drugs they were edged tools in rheumatic disease. The recent reports on the incidence of rheumatism in northern European countries, and especially the British report, were the foundation of the present campaign against rheumatism. These had brought out, *inter alia*, the importance of the climatic factor in causation—that is, the dependence of the rheumatic diseases upon physical influences. The International Society of Medical Hydrology believed that investigation ought to go hand in hand with curative measures, as had been done in the clinics established for various forms of disablement during the war. The committees which the Council had set up in northern European countries had therefore recommended that the treatment to be provided for rheumatic industrial workers should be improved both in quantity and quality. Concurrent investigation and treatment under skilled medical direction was the watchword of their movement. The problem in England and Holland was similar, because natural baths did not exist in Holland and were insufficient

in England to deal with the large numbers of cases involved. In England it was proposed to develop the facilities for treatment at the spas, and also to set up clinics in the towns for systematic investigation and treatment by external and physical methods. During the last half-century physical treatment had been more developed upon the Continent than in England, and the British guests were glad of an opportunity of studying the methods employed at the Clinic in Amsterdam by one who was a European authority on this subject. Thanks to the courtesy of the German authorities, they were also visiting the great hospital for rheumatism at Aachen, directed by Dr. Krebs. England also had great spa hospitals, worthy of comparison with those of any country, and new and valuable methods of hydrotherapy had been devised in England during the war. They were dealing with a group of disabling diseases which were not only an opprobrium to scientific medicine, but inflicted the most serious economic losses upon all the communities of northern Europe, and it was essential for success that they should join forces in a common effort.

Dr. ALISON GLOVER, British Ministry of Health, welcomed the opportunity of visiting the institutions for the treatment of rheumatism at Amsterdam and Aachen. Although uncertainty still surrounded much of the etiology and treatment of chronic rheumatic diseases, their serious incidence was everywhere admitted, and had been clearly shown sixteen years ago in the admirable statistics of the Leipzig Federation of Sickness Funds, and more recently in Sweden by Dr. Kahlmeter. The report of the British Ministry of Health showed that nearly one-sixth of the total sick pay for industrial invalidity was paid on account of these so-called rheumatic diseases, and this great incidence might be accepted as proved, at least for northern Europe. A second point upon which, at all events in England, most people were agreed was that at the present time, of these great hosts of patients only a minority were able to secure in full measure those forms of treatment which were highly beneficial if not essential. Only a minority were subjected to that thorough search for the focus of infection which was so often required. Again, only a very small minority, usually of the better class, in England at any rate, received proper and appropriate physical treatment. The Royal Commission on National Insurance had now recommended that massage and electrical treatment should be made part of medical benefit. Sir George Newman, Chief Medical Officer of the Ministry, had repeatedly urged the necessity for provision of further treatment, and more recently had foreshadowed a scheme which would include three different types of institution, the first being the physical treatment clinic. Such clinics would serve a threefold purpose: First, they would be clearing houses, directing patients to the form and place of treatment suited to their need, some to spa treatment, some for intensive study at an arthritis unit, whilst others would be greatly benefited by treatment at the clinic itself. Secondly, therefore, these clinics would be out-patient institutions, to supply those forms of physical treatment which were so often necessary for the re-education of muscles and joints, and generally for after-treatment when the active stage had passed. Thirdly, they should be organized in close co-operation with the arthritis unit and with the spa hospital, and provide continued supervision, observation, and after-care, following institutional treatment. Such clinics would be also of great service in diseases and conditions other than rheumatic, such as fractures, deformities, and diseases of the nervous system. The second type of institution foreshadowed was the arthritis unit, which should be in closest co-operation with a large teaching school of medicine or university, enabling it to fulfil the purposes of research and observation as well as teaching. It would also act as a place of preliminary treatment or preparation for spa treatment. Patients would be admitted at the earliest possible stage for thorough examination by modern methods. The focus of infection would, if possible, be found and removed; bacteriological and biochemical investigations would be completed and a diagnosis made before the patient was passed on to another institution, and orthopaedic surgery would if necessary be used. Such a unit would furnish opportunity

for team work in both research and treatment. The third type of institution was the spa hospital, organized in closest co-operation both with the arthritis unit and with the physical treatment centre. The hospitals at Bath, Buxton, and Harrogate suffered from the fact that many of their 650 beds were occupied by advanced cases. The patients having been thoroughly examined and the preliminary treatment completed at the arthritis unit, spa treatment would be much more beneficial and the duties of the spa physician simplified.

Dr. KREBS described the treatment of insured rheumatic patients at the Landesbad at Aachen, of which he is director.

Dr. VAN BREEMEN protested against the common opinion, even in medical circles, that the control of rheumatic diseases was impossible. Many facts had been published, and many results put on record by well known medical men, proving that successful treatment was possible, even with the present poor organization. He believed that when the family doctor had received in the university medical education in the diagnosis and treatment of rheumatism the results would be much better. But more was required than the family doctor in contending against these diseases. A special hospital for rheumatism was needed, with a laboratory for scientific study. It had been demonstrated, especially in America during the last twenty-five years, that hospitals for particular diseases were of great advantage to the patients and to science. Holland might be made an important centre for the study of the rheumatic diseases, but both energy and funds were needed for this purpose. Moreover, "every disease with a social significance must be fought at the beginning and not at the end."

On the following day the conference was resumed at Aachen, where Dr. KREBS and his assistants demonstrated the organization of the Landesbad, erected by the friendly societies of the Rhine Provinces in 1912 for the use of their members suffering from rheumatic diseases. The cases, usually in an early stage of disease, are selected by a commission at Düsseldorf. There are 360 beds and a complete system of physical treatment.

## THE HEALTH OF SCOTLAND.

### REPORT OF THE REGISTRAR-GENERAL FOR 1925.

THE seventy-first annual report of the Registrar-General for Scotland, dealing with the year 1925, has just been issued. The population of Scotland in the middle of the year is estimated as 4,893,032—an increase of 11,395 over that of the previous year, and 10,535 more than the population of Scotland as ascertained by the census of 1921. Of the total population, 2,352,708 were males and 2,540,324 females. There was an excess of emigrants from Scotland over immigrants into Scotland of 28,430. The births registered during the year were 104,137; this number is 2,765 fewer than that of the previous year, and is less than that of any year since 1858, with the exception of the war years 1917 and 1918. The birth rate for the year was 21.28 per 1,000, the lowest yet recorded, with the exception of the two war years mentioned above. There were 6,831 illegitimate births registered during the year—the smallest number yet recorded, being 255 less than those of the previous year; they constituted 6.55 per cent. of the total births registered. The marriages registered during the year numbered 32,473, which is 145 more than in the previous year, but 5,107 fewer than the mean of those of the preceding five years, and less than those of all years since 1910, with the exception of 1911, 1916, 1917, and 1924. The deaths registered during the year numbered 65,507; this is 4,850 fewer than in the previous year, 2,680 fewer than the mean of the deaths in the preceding five years, and 6,114 fewer than the mean of those in the preceding ten years. This is the smallest number since 1851, with the exception of 1923. The annual death rate was 13.39 per 1,000, which is 1.02 less than that of the previous year. This is the third year in which the Scottish death rate has been less than 14, the two previous occasions being 1921 and 1923, with death rates of 13.56 and 12.91 respectively. The number of reputed centenarians whose deaths were recorded and verified during the

year was 8. The investigation of cases dying at a reputed age over 100 has now been made for sixteen years, and in all 224 reputed centenarians have been dealt with; in 103 instances the attainment of the age of 100 has been verified, in 29 contradicted, while in 92 no satisfactory proof of age was obtainable. Among the causes of death found to be more than usually prevalent during the year were cancer, puerperal conditions, whooping-cough, and violence, while among those causes which had decreased were measles, diphtheria, tuberculosis, syphilis, bronchitis, and pneumonia.

### Death Statistics.

Of the 65,507 deaths registered, 33,036 were of males and 32,471 of females. The death rate in the male population was 14.04, and in the female population 12.78 per 1,000. When the deaths are distributed according to the place of usual residence it is found that 34,046, or 52 per cent., occurred among the population of the larger burghs; 12,444, or 19 per cent., among that of the smaller burghs; and 19,017, or 29 per cent., among that of the county districts. In the larger burghs taken collectively the crude death rate of the year was 14.94 per 1,000, the corrected death rate 14.36; in the smaller burghs taken collectively the crude death rate was 12.14 and the corrected death rate 13.10; and in the county districts taken collectively the crude rate was 11.8 and the corrected death rate 12.1. Of the larger burghs the death rates of the year were 17.4 in Perth, 17.1 in Dundee, 16.1 in Edinburgh, 15.8 in Kilmarnock, 15.4 in Glasgow, 10.4 in Motherwell and Wishaw, 10.6 in Hamilton, and 7.6 in Clydebank. Of the smaller burghs, exclusive of those with populations of less than 1,000, the crude death rate of the year varied from 27.1 in Whithorn to 3.7 in Ballater. In the county districts the crude death rate varied from 23.1 in the western district of Ross and Cromarty to 6.3 in the Laurencekirk district of Kincardine. Out of the total 65,507 deaths, 14,249, or 21.7 per cent., were of children aged less than 5 years; 26,525, or 40.5 per cent., were persons aged 5 to 65; while 24,733, or 37.8 per cent., were of persons aged 65 and over. Compared with the previous year, the deaths of children under 5 were 2,767 fewer, those of persons from 5 to 65, 906 fewer, and those of persons of 65 and over, 1,179 fewer. The average age at death of all persons dying during the year was 46.64 years—that of males being 44.15 and that of females 49.17. Deaths of children aged less than 1 year numbered 9,430 (1,016 fewer than in the previous year). This is the third year in which deaths of children under 1 year of age have numbered less than 10,000, the previous occasions being in 1918 with 9,836 deaths, and 1923 with 8,825 deaths. The infantile mortality rate of the year was 99.6 per 1,000 registered births, which is 7.1 less than that of the previous year, 1.5 less than the mean of the infantile death rates in the preceding five years, and 8.7 less than the mean of those in the preceding ten years. It is lower than the Scottish infantile mortality rates of all previous years with the exception of 1921 and 1923, when the rates were 90.3 and 78.9 respectively. It compares favourably with infantile mortality rates from 1855 to 1915, which never fell below 100 and were usually over 110. Since 1915 the infantile mortality rate has been under 100 on seven occasions and above 100 three times.

### Causes of Death.

Of the 65,507 deaths, 65,009, or 99.2 per cent., were certified by a registered medical practitioner or by a procurator-fiscal. The remaining 498 uncertified deaths is the smallest number yet recorded. In 64,355 instances, or 98.1 per cent. of the total, the cause of death was definitely specified, while in 1.5 per cent. there was an unsatisfactory entry such as "sudden death," "heart failure," or "natural causes." With regard to the infectious fevers, deaths from enteric fever numbered 52. It is pointed out that from 1865 to 1882 deaths from this cause annually numbered more than 1,000, and from 1883 to 1903 more than 500. Since this time enteric fever as a cause of death has been diminished, the smallest number of deaths in any one year having been 34, in 1924. Typhus fever was responsible for 4 deaths, all in Greenock, and it is pointed out that from the year 1865 to 1871 the deaths from this cause

constantly numbered more than 1,000 annually. No deaths from small-pox were registered, and there had been no deaths from this cause since the year 1921. Measles was responsible for 512 deaths, which are 1,080 fewer than in the previous year. This is the smallest number of deaths from measles with the exception of the number 269 registered in 1921. Scarlet fever caused 404 deaths, this number being 6 fewer than in the previous year. It is pointed out that from 1855 to 1876 these deaths constantly numbered more than 2,000 annually, and were at a maximum of 6,321 in 1874. The smallest number in any one year was 168 deaths, registered in 1918. Whooping-cough caused 1,737 deaths, which were 112 more than those of the previous year. The deaths due to diphtheria numbered 505, being 63 more than in the previous year; before 1896 deaths from this cause constantly numbered over 1,000, but since 1897 the number has been gradually falling. Among the other epidemic diseases, encephalitis lethargica was responsible for 154 deaths, erysipelas for 150, cerebro-spinal meningitis for 83, infantile paralysis for 21, malaria for 9, and dysentery for 7. The deaths from encephalitis lethargica were 27 fewer than those of the previous year. Deaths from influenza in all numbered 1,246. This number is 1,244 fewer than in the previous year, and compares favourably with 11,111 deaths in 1918, 7,215 in 1919, and 3,706 in 1922. The number in the year under review is smaller than in any year subsequent to 1917, with the exception of 1923. Tuberculosis in all forms was responsible for 5,390 deaths. This number is 263 smaller than in the previous year, 418 fewer than the mean of the numbers for the preceding five years, and 1,228 fewer than the mean of those of the preceding ten years. It is the smallest number of deaths from tuberculosis yet recorded in Scotland. It is pointed out that in 1870 deaths from tuberculosis in Scotland attained a maximum of 13,027. The annual number fell below 11,000 in 1884, below 9,000 in 1910, and below 7,000 in 1919; the present is the fifth consecutive year in which these deaths have numbered fewer than 6,000. Of the 5,390 deaths ascribed to tuberculosis, 3,734 were due to tuberculosis of the respiratory system—153 fewer than the corresponding figure for the previous year, and the least number of deaths from this cause yet recorded in Scotland. In the larger burghs taken collectively the death rate from tuberculosis of the respiratory system was 91 per 100,000, in the smaller burghs 65, and in the county districts 62. The deaths due to malignant disease numbered 6,675, constituting a death rate of 136 per 100,000. Both the number of the deaths and the rate are the highest yet recorded, the deaths being 177 more than in the previous year, 528 more than the mean of the numbers of the preceding five years, and 862 more than the mean of those of the preceding ten years. The male death rate from this cause was 129 per 100,000, and the female death rate 144. Of the total number, 4,679 were ascribed to carcinoma, 266 to sarcoma, and 1,730 to other specified forms of malignant disease. The most frequent sites of malignant disease among males were: stomach 763, intestines 490, rectum 238, liver 193, oesophagus 155, prostate 136, and tongue 199, an order of frequency the same as in the previous year. The most frequent sites among women were: stomach 748, intestines 585, breast 566, uterus 461, liver 294, and rectum 186. Diabetes was responsible for 457 deaths, of which 168 were males and 289 were females. It is pointed out that deaths from diabetes in recent years have shown a considerable diminution, especially in the male population. Syphilis was the stated cause of death in 114 instances, a number 37 less than in the previous year. Pernicious anaemia was stated as the cause of death in 447 cases. The total number of deaths attributed to pneumonia during the year was 5,821, including 428 deaths from pneumonia associated with influenza. This number is 1,870 less than that for the previous year. Deaths attributed to violence numbered 2,817, which is 218 more than in the previous year.

#### Vaccination.

The report deals especially with the vaccination of children born in the year 1924, who in ordinary course should have been vaccinated during that year or during the first half of 1925. Of the 106,901 children born in 1924,

99,077 survived at the age of 6 months, when statutory vaccination should have been carried out. Of these, 62,382, or 62.96 per cent., were either certified as having been successfully vaccinated or were reported to be unsusceptible to vaccination. The number not reported to be vaccinated was 35,808, or 36.14 per cent., of whom 29,568 remained unvaccinated by reason of a declaration of conscientious objection on the part of the parents. It is pointed out that prior to the passing of the Vaccination (Scotland) Act of 1917, which made conscientious objection of parents a valid reason for avoiding statutory vaccination, more than 91 per cent. of the surviving children were successfully vaccinated. Since this there has been a gradual annual fall in the number vaccinated, with the exception of the year 1920, in which there was an epidemic of small-pox in Glasgow, when the percentage rose temporarily to 70.54.

## VOLUNTARY HOSPITALS IN GREAT BRITAIN.

### SEVENTH ANNUAL REVIEW.

THE seventh annual report on the voluntary hospitals in Great Britain, excluding London, for the year 1925 has just been issued. It has been compiled by Mr. R. H. P. Orde, acting director of hospital services, Joint Council of the Order of St. John of Jerusalem and the British Red Cross Society, and has an introduction by Sir Arthur Stanley, Chairman of the Joint Council. A summarized record of the work of 749 hospitals is given, and an attempt is made to define the position of the provincial hospitals of Great Britain in respect of the facilities provided for treatment, the extent to which they are utilized, the annual cost of maintaining them, and the sources of the funds concerned. These subjects are illustrated by fifty-one tables. Since the publication of the last report the area covered by King Edward's Hospital Fund for London has been enlarged to include twelve hospitals with a total of 332 beds, which were previously considered extra-metropolitan. The present report deals with 749 of the 791 provincial voluntary hospitals, the exclusion of the remainder being due to failure to issue reports, or to forward them in time to the Joint Council.

#### Financial Position.

During 1925 the total receipts of the hospitals under review amounted to £8,139,220; of this total the expenditure on maintenance and development accounted for £7,121,090, leaving a surplus of £1,018,130. More than 75 per cent. of the hospitals at the end of the year had a credit balance in their maintenance accounts. With the exception of 1924, there has been an annual improvement in the financial position since 1920, and the invested funds have increased during the same period by nearly £6,000,000. Taking the English provincial hospitals as a whole, the percentages of the income obtained from the three sources of interest from investments, voluntary gifts, and earnings was 15.1, 63.5, and 21.4; the corresponding figures in the case of 118 London hospitals were 21.8, 43.6, and 34.6. The support received in the form of subscriptions to the provincial hospitals was greater in 1925 than in any of the previous five years, and the level of donations was well maintained. The amounts derived from the various forms of contributory schemes have grown from £25.22 per available bed to £35.58. It is shown further that hospitals with highly developed contributory schemes have overcome their financial difficulties to a large extent, there being no apparent difference in this respect between industrial and agricultural areas. In the large hospitals this source of income was double that of any of the other principal sources. The amount derived from the public services has fallen to less than 10 per cent. of the total income; contributions in respect of military and pensioner patients have almost ceased, but with the increasing co-operation between the State and voluntary hospitals the income under this head is likely to increase. In Scotland, where receipts from legacies form a very important part of hospital income, there was a diminution in this respect during the year under review, but, nevertheless, there was a surplus of receipts over expenditure of £308,146. The financial stability of Scottish hospitals is further shown by the fact that, whereas in 1920 the deficit of ordinary income

amounted to £78,158, in 1925 it was only £17,397, and to meet this deficit there was available a sum of £227,537 from free legacies.

#### General Statistics.

In round figures over half a million in-patients and two and a quarter million out-patients were treated in the English and Welsh provincial hospitals during the year, the Scottish figures being 117,000 and 376,000 respectively. This represents an increase on last year of 40,000 in-patients and 150,000 out-patients. A complaint is made that the lack of uniformity in presenting the statistics in hospital reports, particularly in regard to the number of out-patients, is the cause of much confusion and even inaccuracy. It is suggested that the records of out-patients should include the numbers treated under such headings as medical, surgical, ophthalmic, and aurial, while the out-patients' statistics should be tabulated to show the various departments, such as casualty, medical, surgical, and ophthalmic. The number of new patients should be recorded separately from the subsequent and total attendances. It is added that the volume of work performed by the voluntary hospitals is one of the fundamental factors in establishing a basis of defence for them as a system, and the details provided should, therefore, be full and accurate.

#### Evolution and Progress.

According to the practice established two years ago, the report contains special articles on matters of importance to hospital authorities. Mr. Thomas A. Pole, F.R.I.B.A., gives a very interesting account of one hundred years of hospital planning—1825 to 1925—illustrated by simple block plans. The general arrangement of the various component parts, such as wards, operating theatres, administrative blocks, and so on, is shown to have improved very obviously during this period, and the importance of making no initial mistakes in arranging the various blocks when planning a new hospital is emphasized. Thus an adequate and well placed store accommodation, for example, may easily be the means of reducing the annual wage bill. The recent increase in the number of small hospitals providing about thirty or forty beds has given scope for much ingenuity in construction, although such buildings are inevitably relatively expensive. On the other hand, there is some danger of an institution of more than 500 or 600 beds becoming too unwieldy for proper administration, and there is a tendency in the large towns to establish branch hospitals on the outskirts. Mr. Pole believes that in the future the original central buildings will function as emergency units, the real hospitals for treatment and convalescence being placed on the outskirts of the cities on ample and open sites free from encroachment.

Sir Basil E. Mayhew discusses the *Revised Uniform System of Hospital Accounts*, issued in January, 1926, and referred to in the *Journal* of May 8th and 15th (p. 843). Dr. G. F. Barham, medical superintendent of the London County Mental Hospital, Claybury, in a thoughtful account of the relation of mental hospitals to other medical institutions, appeals for closer co-operation between general hospitals, clinics, and mental hospitals. He advocates affiliation between a mental hospital and the nearest general hospital, if possible with a school of medicine attached, in order that the means of treatment of mental disease may be increased, research work organized, psychological medicine be taught more extensively, and better facilities be acquired for training nurses. He envisages the formation of homogeneous units within a scheme of hospital organization to include the clinic of a general hospital, a reception hospital, and a mental hospital. He asks for much greater freedom for the treatment of mental cases in clinics and private hospitals, together with the adoption of the voluntary system on the widest basis compatible with security. He also desires improved education of public opinion in regard to mental disorders and the need for early treatment; all semblance of compulsion and detention should be removed as far as possible. The subject of providing beds for paying patients in voluntary hospitals is dealt with in a series of short articles by twelve hospital secretaries. Reference is made to the paper by Mr. A. G. E. Sanctuary mentioned in the *Journal* on April 24th, 1926 (p. 740).

Sir John Robertson, medical officer of health for Birmingham, appeals for the establishment of maternity wards in general hospitals, and expounds the advantages of combining maternity work with general hospital treatment. He does not think, however, that there will be any very large call on hospitals for maternity beds until the public generally realizes the advantages of the hospital over the home, not only in complicated, but also in uncomplicated confinements.

## New Zealand.

[FROM OUR SPECIAL CORRESPONDENT.]

#### POST-GRADUATE OBSTETRIC TRAINING.

The view that the post-graduate instruction of medical practitioners in obstetrics is necessary, even if only to combat the very prevalent belief that surgery is the cure for lack of obstetrical experience, is advanced by Dr. Henry Jellett of Christchurch, consulting obstetrician to the Health Department of New Zealand, in a report to the department on the subject of maternal welfare. He adds: "I refer particularly to the increasing tendency, not only in New Zealand but elsewhere, to perform Caesarean section for many types of obstetrical complications." A movement is on foot within the New Zealand Branch of the British Medical Association to establish a New Zealand Obstetrical Society. This society will be able to collect and collate valuable data. The maternal mortality in New Zealand is rather higher than it should be in comparison with several other countries, and assuming that statistics are to be wholly relied upon, there must be a higher incidence of obstetrical abnormalities in New Zealand or a not altogether satisfactory standard of technique on the part of doctors and nurses.

#### UNREGISTERED DENTISTS.

There is an excellent dental school at Otago University which should be the only avenue through which dental students proceed to qualification in dental practice. Already since the war special examinations of low grade have been granted to dental students, and indeed to dental mechanics, who had served in the war and whose course of training had been in that way interrupted. Political agitation, however, has been active to open further the door of easy access to the profession; it has been resisted not only by the Dental Association but by the medical profession. A Royal Commissioner was recently appointed to report on the whole matter, and his report has caused consternation to those who think that the standard of dental education should be under the control only of the Senate of the New Zealand University. The report is unjust to the students who incur the expense and labour of the regular statutory course in dentistry. The Commissioner recommends that fifty-seven unregistered dentists, whose names are listed should be allowed to sit for examination prescribed by the New Zealand University Senate, on the recommendation of the Dental Faculty of the University of Otago. The examination is to be as nearly as possible similar in character to, but not lower than, that prescribed in 1922 and 1923. The Commissioner recommends that one examination be held in December, 1927, and a second in December, 1928, for applicants who may not satisfy the examiners in 1927. It is also recommended that legislation be passed to allow the fifty-seven dentists named to practise until March 31st, 1929, pending registration. Thirty-two of the fifty-seven dentists are classified as returned soldiers, and six are discharged soldiers who served in New Zealand only. An Act to give effect to the terms of this extraordinary report was passed by the New Zealand Legislature.

#### TREATMENT OF LEPROS.

A leper station is established at Makogai Island in Polynesia, and 308 lepers are under treatment. New Zealand accepts liability for 63, including 12 from Samoa and 41 from Cook Islands and Niue. The number discharged cured since the station was opened in 1911 and up to June 30th, 1926, was 119. Sixteen others are under observation but have not yet been without signs of disease.

for two years. The medical superintendent includes in his methods of treatment moogral, pure chaulmoogra oil, urotropine intravenously, and sodium morrhuate by deep subcutaneous injection. Injections of neokharsivan are given for yaws complicating leprosy. It is exceedingly difficult, says the medical superintendent, Dr. Neff, to give any accurate estimation of the value of any specific treatment for leprosy. As a general rule cases of nerve leprosy tend to improve of themselves if under good hygienic conditions, which include their separation, as far as practicable, from the nodular cases. Many nodular cases also improve slowly; they are, however, liable to relapses, and on that account should not be discharged.

## England and Wales.

### ANTE-NATAL WORK AT THE BRISTOL ROYAL INFIRMARY.

The governors of the Bristol Royal Infirmary recently resolved to add to the honorary staff an assistant physician who should be in charge of the ante-natal department. This department began in 1921 with the establishment of an ante-natal clinic in the department of obstetrics, under Professor Walter Swayne. Dr. Lily Baker, then obstetric registrar, took charge of the clinic, and under her care it developed so rapidly that now 1,250 new cases attend annually. The benefits derived can be judged from the fact that the incidence of difficult and dangerous cases in the obstetric department has fallen by almost 50 per cent., and proper precautions can be taken to deal with those which may inevitably occur. On October 26th, the election committee of the governors, with the unanimous support of the honorary medical staff, elected Miss Lily Baker, B.A., M.B., B.Ch.Dubl., F.R.C.S.I., to occupy the new position on the staff, and in so doing created, we believe, an important precedent, for general hospitals with teaching schools, of appointing a woman to full membership of the honorary medical staff. Dr. Lily Baker took many prizes and honours as a student, and has had a distinguished career since qualifying. Soon after the beginning of the war she became acting obstetric registrar at the Bristol Royal Infirmary when the late Professor Walter Swayne was away on military service. On his return she joined the W.R.A.F. and served in France and Germany until the end of 1919. Since 1915 she has been an examiner and recognized lecturer to the Central Midwives Board.

### ST. THOMAS'S HOSPITAL DINNER.

Old students of St. Thomas's Hospital to the number of two hundred or more gathered at the Hotel Victoria at dinner on October 29th. Dr. R. Percy Smith was in the chair, and among the guests were Sir John Rose Bradford (President, Royal College of Physicians), Sir Arthur Stanley (treasurer of the hospital), Surgeon Vice-Admiral Sir Joseph Chambers (Medical Director-General R.N.), and Lieut.-General Sir Matthew H. G. Fell (Director-General A.M.S.). The chairman devoted his speech to personal reminiscences, extending back over half a century, of the hospital and school, and described some famous old figures at St. Thomas's during the last generation. Sir Arthur Stanley preferred to speak rather of the present and future, and referred to the developments which had been made possible by the generosity of the Rockefeller Foundation on the one hand, and the faith and courage of the medical school in rising to the occasion on the other. He mentioned that this was the last year, in all probability, in which the old students would meet for their annual dinner anywhere save in their own home, for the club opposite the hospital was approaching completion. Here, by the way, was already housed the finest collection of cups of which any hospital in the country could boast. Another benefactor to whom he had to allude in speaking of the new extensions was Lord Riddell, who, when he (Sir Arthur Stanley) was endeavouring to prove to his fellow governors that the proposition was not a sound one financially, promptly made it so by coming forward and lending a very large sum of money at a very low rate of interest. The

dean of the school (Sir Cuthbert Wallace) made feeling reference to some outstanding St. Thomas's men who have passed away during the year. Among various matters of domestic interest on which he touched was the fact that forty sons of old students are in the school at the present time. Lord Riddell, in response to the toast of his health, proposed by Dr. J. S. Fairbairn, acclaimed the medical profession as the virtual rulers of society, in succession to the priests of ancient times and the kings of a more modern order. The whole object of civilization was to improve health and extend life. The doctor, he said, had surveillance over the individual from the cradle to the grave. A very successful evening ended with many compliments to the chairman, voiced by Sir George Makins.

### NOTIFICATION OF OPHTHALMIA NEONATORUM.

The new public health (ophthalmia neonatorum) regulations place the responsibility for the notification of ophthalmia neonatorum upon the medical practitioner in charge of the case, and the Ministry of Health is urging upon local authorities the importance of refraining from any action likely to deter midwives from promptly seeking medical aid in all cases of inflammation of or discharge from the eyes of infants. To that end it suggests that local authorities should not in future exercise their power to recover from the parents the fee paid to the medical practitioner called in by the midwife. Hitherto the London County Council has taken steps to recover such fees on a scale graduated according to the family income and the number of dependants. The Midwives Acts Committee reports that for a long time it has been impressed with the difficulties surrounding cases of inflammation of or discharge from the eyes of infants. Midwives have been reluctant to obtain medical assistance, in many cases because they shrank from involving their patients in charges for medical attendance. Often, when the onset has appeared to be mild, they have tried to treat the eyes themselves. The committee concurs in the view of the Ministry that nothing should be done which would be likely to deter midwives from promptly seeking medical aid in such cases, and therefore it recommends that no steps be taken to recover the fee paid to the practitioner. The amount hitherto recovered by the Council from patients or other persons responsible has been about £150 a year.

### OSHEHAMPTON AND DISTRICT COTTAGE HOSPITAL.

The Okehampton and District Cottage Hospital, which has been built at a cost of £6,700, as a war memorial, was opened formally on October 20th. The site of the hospital was presented by the mayor and mayoress, Mr. and Mrs. Blatchford, and largely through efforts of ex-service men the greater part of the money required was quickly raised. The foundation stone was laid on May 27th, 1925. The building, which faces southwards, has a view of the moors across the valley, and the ground floor contains two wards for four beds, as well as the matron's room, surgery, dispensary, and the operating room. On the first floor there are two private wards, a staff common room, and bedroom accommodation for seven. A well planned sanitary wing with good ventilation is situated on the north side of each ward, and there is a possibility of extension of the main wards, if required at a future date. Dr. E. H. Young, chairman of the hospital, described how the ex-service men had urged five years ago that the war memorial should take the form of a hospital. In view of the long waiting lists of the hospitals at Exeter and Plymouth, he believed that a valuable service was being rendered by the provision of this new hospital, which would not compete with the larger ones elsewhere, but would be able to ease the pressure on their accommodation.

### THE SURGEONS' DEBT TO THE INSTRUMENT MAKERS.

The members of the Surgical Instrument Manufacturers' Association met at dinner at the Holborn Restaurant, London, on October 29th, with Mr. Ernest W. Mayer in the chair. Among the principal guests were Dr. Irwin Moore and Mr. L. Ferris-Scott, Financial Secretary and Business Manager of the British Medical Association. Dr. Irwin Moore complimented the industry upon its efficiency in design and production, and, speaking as a

laryngologist and aural surgeon, he traced the progress in his specialty during recent years. Removal of the enlarged and unhealthy tonsil had, he said, now been converted into practically a bloodless operation, thanks to the instruments which had made possible the improvement in technique. In early cancer of the larynx, thanks again to instruments of precision, cures could now be obtained in 80 per cent. of the cases, as contrasted with 14 per cent. operation mortality and 43 per cent. recurrences thirty years ago. For more advanced cases the instrument makers had supplied an artificial larynx, by means of which the patient was able to speak in an audible voice. With regard to operations on the mastoid and labyrinth there were most delicate and intricate instruments available for the restricted area. No greater development had taken place in the recent history of surgery than peroral bronchoscopy. The present-day oesophagoscope and bronchoscope had evolved from the endoscope of Richard Cruise and the auroscope of John Brunton, two pioneers to whom all homage was due. The case of the celebrated engineer Brunel illustrated the helplessness of the surgeon eighty years ago. Brunel accidentally inhaled a half-sovereign into the bronchus. In those days the recognized method of treatment was to hold the patient upside down and strike him on the back; if this failed tracheotomy was performed. Ordinary inversion failing in the case of Brunel, Sir Benjamin Brodie opened his trachea and made a number of unsuccessful attempts to reach the coin by inserting forceps through the wound. Brunel himself, however, being an engineer, came to the rescue and designed a revolving platform, hinged so that one end could be elevated or lowered, and, strapped prone on this, his head and trunk were suddenly depressed while he was violently struck on the back. The coin fortunately was shot out of his bronchus into his mouth and fell on the floor. This "inversion" period, Dr. Irwin Moore added, continued up to twenty-five years ago, when the practical utility of the direct method of bronchoscopy was first demonstrated. In the case of foreign bodies accidentally aspirated into the respiratory tract the mortality had been reduced from the 52 per cent. of the pre-laryngoscopic period to between 5.3 and 1.7 per cent., depending on the skill and experience of the operator. In the case of foreign bodies impacted in the food passages the mortality had been reduced to 3 per cent. Mr. Ferris-Scott, who also responded for the guests, recalled the tribute which a past President of the British Medical Association, Sir William Macewen, had paid to the surgical instrument makers when he said that no matter what skill the surgeon might have at his command, unless he had proper instruments he was as helpless as a tyro. Other speakers were Mr. P. C. Maw and Colonel A. Young. The chairman emphasized the merits of the British industry, and referred regretfully, as did other speakers, to their inability as yet to obtain protection under the Safeguarding of Industries Act.

#### SIR JAMES BARR.

Sir James and Lady Barr were entertained by the Liverpool Ulster Association, of which Sir James is president, at a farewell dinner at the Exchange Station Hotel on October 26th. Dr. T. Clarke presided over a large gathering of the committee and ladies, and, in proposing the health of the guests, said that Sir James Barr had never forgotten his old country, but had always stood forth as an Ulsterman. Sir James Barr, who was received with musical honours, said he had always been proud that he was an Ulsterman, but never prouder than during the war, when Ulster did her duty, and even more. It was a painful thing, continued Sir James, for Lady Barr and himself to leave Liverpool, but after fifty-two years' hard work in the city he felt he was entitled to a little leisure. They were not leaving through ill health. It was far better to retire in the full enjoyment of life than to wait until a senile condition was reached. They were not going to lead an idle life; he could not be happy if he had nothing to do. As far as his professional work was concerned, he had taken a special interest in preventive medicine ever since he devoted himself to the subject as

medical officer at Kirkdale Prison in 1877 and 1878. He wanted people to look after their health just as much as they attended to their diseases.

#### PART-TIME MEDICAL OFFICERS OF THE LONDON COUNTY COUNCIL.

Assistant medical officers employed by the London County Council on part-time engagements for the school medical service are paid inclusive salaries of £360 a year and £180 a year for six and for three half-days' duty a week respectively. It has been found necessary to fix a basis of calculation in connexion with payments to such officers in respect of half-days worked in excess of the number indicated in the terms of their engagements, and with deductions from salaries in respect of leave of absence in cases in which full pay is not allowable. It has been reckoned that normally the two classes of medical officers work about 264 half-days and 132 half-days a year respectively, and the Council has decided to fix the basis of calculation of pay accordingly. A year's duty is therefore to be reckoned as 264 half-days a year in the case of officers appointed for six half-days a week, and 132 half-days a year in the case of those appointed for three half-days a week.

## Scotland.

#### VETERINARY SCIENCE IN SCOTLAND.

THE annual report of the Royal (Dick) Veterinary College at Edinburgh for its 103rd session, 1925-26, has just been issued. This shows the wide area from which students are drawn, as 22 counties in Scotland, 15 in England, and 5 in Ireland had been represented, while students also came from South Africa, India, Palestine, Peru, and the Malay States. The number of graduates attending advanced courses of instruction had steadily increased, and it had been found that the opportunities for post-graduate study had been a source of inspiration to students taking the ordinary professional curriculum. A centenary post-graduate fellowship of the annual value of £250 had been instituted as a permanent memorial of the 100th anniversary of the College's foundation; the first Fellow elected during the past session had been pursuing an investigation on animal tuberculosis, working both in the Dick College and in Paris. New buildings for classrooms, laboratory, and hospital had been opened by the Secretary of State for Scotland during the year, and a recent development had been diagnostic work in diseases of poultry; by an arrangement with the Scottish Board of Agriculture, poultry-keepers were now able to obtain information and advice regarding disease among their stock.

The Glasgow Veterinary College held its annual prize distribution on October 19th. Professor Glaister, chairman of the governors, who presided, drew attention to the fact that the College was now existing under some financial difficulty. The governors had determined to carry on the College despite the withdrawal of the grant from the Board of Agriculture in Scotland. The appeal for funds had brought in about £8,000. The certificates and prizes gained during the last session were then presented by Sir Charles Cleland, chairman of the Glasgow education authority, who remarked that the College was passing through a testing time; it was expected that the students, teachers, and governors would do all they could to increase the efficiency of an institution which had done excellent work in past years. While they felt respect for the institution housed in Edinburgh, they believed there was ample room for a Glasgow college as well, and he thought that the future was bright, as veterinary medicine was more and more being associated with the great subject of public health.

#### AFTER-CARE PROBLEMS OF MENTAL DEFECT.

A conference under the auspices of the Scottish Association for Mental Welfare was held on October 22nd in the Training College, Dundee. Miss Evelyn Fox, honorary secretary of the Central Association for Mental Welfare, London, read a paper on after-care of mental defectives, in which she referred to the fact that Scotland was in the

forefront in the scientific and humanitarian care of the insane, and expressed the hope that the after-care of the mental defective would shortly be extended. Mental welfare work fell into two sections—the care of defectives in schools and the care and protection of defectives in the community. Provision should be made to give defectives, on leaving institutions, amusement and recreation suitable for their limited mentality, and also for handicraft classes and workshops under conditions adapted to their temperament and physique. In a paper by Dr. Eichholz, chief medical inspector, Board of Education, London, it was stated that roughly 60 per cent. of the whole ascertainable number of educable mental defectives were at present receiving instruction. Under a well managed scheme of after-care it should be possible to place at work from 45 to 50 per cent. of these pupils; 20 or 30 per cent. of them would probably require custodial care, and the remainder would require close supervision in order to keep them at work. Dr. Jardine, medical officer of the Scottish Education Department, said that in 1919-20 the number of children attending special schools or classes in Scotland was 2,449, while in 1924 the number had increased to 3,440. In Glasgow the proportion was 114 per 10,000 children, in Edinburgh 64, in Aberdeen 60, and in Dundee 23. At the present time there was accommodation for 3,500 children in special schools in Scotland, but according to his calculation there was need for provision for 7,500. Professor W. W. McClelland, director of studies, Training College, Dundee, referred to the special classes for backward children which might be attached to ordinary schools. It was a mistake to condemn a child prematurely to the special school, because undoubtedly a certain stigma attached. Dr. Chislett, superintendent, Stoneyetts Institution, Glasgow, who read a paper on the institutional care of the adult defective, said it was a matter for regret that now, nearly thirteen years after the passing of the Mental Deficiency Act, Scotland had done very little towards providing colonies for adult mental defectives, especially when it was remembered how much had been accomplished by the various institutions for mentally defective children. All the dangers of mental deficiency to the community arose from the adult defective. After-care associations concerned with visiting defectives in their homes and with boarding them out in supervised private dwellings did some good, but there were many adults whose freedom was a menace both to themselves and to the community at large. The only suitable treatment for these was segregation and a continuation of the treatment they had received as children. Colonies where this could be carried out were imperative. The attention of the local authorities had of late been directed more and more to the mentality of the criminal classes, and prison medical officers had for many years been ready to admit mental defect as accounting for certain criminal propensities. Dr. Clarkson (Larbert) said that a State institution for criminal defectives in Scotland was urgently required.

#### INDUSTRIAL HEALTH.

The Industrial Health Education Council, which was formed in 1922 for the purpose of disseminating knowledge likely to prevent disease and accidents to people engaged in industry, held its first meeting for the new session in Edinburgh on October 27th. Originally this was a purely Scottish organization, but its activities, having recently been attended with considerable success, have been extended into England and Wales. In order to meet with growing demands from England the Council has now formed itself into an Industrial Health Education Society for the United Kingdom. Sir William Haldane, W.S., Edinburgh, who was in the chair, said that there had been a great demand from over the border for the work and help and guidance of the Council, and the Ministry of Health had asked it to extend its work in the south. Sir Malcolm Smith said that the success of the effort had been surprising: there was evidently a field in the industrial world awaiting development, for the people were very anxious to get information as to the means of maintaining their health and of avoiding illness. He believed that the organization would in time become of still greater importance and that it might be taken over by the Government.

## Ireland.

### ULSTER MEDICAL SOCIETY.

THE opening meeting of the session of the Ulster Medical Society was held in the Medical Institute, Belfast, on October 28th. The outgoing president, Mr. J. A. Craig, F.R.C.S., introduced his successor, Dr. M. J. Nolan, medical superintendent of the Down District Lunatic Asylum. After the minutes had been read, the President called on Dr. A. F. Hurst of Guy's Hospital, London, who read a paper on "The constitutional factor in disease." Dr. Hurst referred to the old conception "diathesis" in relation to disease, so popular in France many years ago, and to the disuse into which the term had fallen in England; this was due to the scientific methods in examination which had been more and more used as chemistry and, later, biochemistry were developed. Too much attention had been paid in modern methods to parts of the body, too little to the patient as a whole—that is, to a biological knowledge of the constitution. Taking the stomach as his first instance, Dr. Hurst said that great variations had been found in its anatomy, and its functioning or chemistry; the normal, average, or orthotonic stomach was, as regards size, found in 80 per cent. of healthy persons, but in 4 or 5 per cent. there was the short stomach, supposed erroneously to be due to hypertone, and in 4 or 5 per cent. the long stomach, supposed to be due to want of tone, and called gastropotosis; as the transverse colon follows the lower border of the stomach, similar descriptions were given of it. In about 50 per cent. of individuals the quantity of hydrochloric acid in the stomach secretion was average or normal, but 4 or 5 per cent. had hyperchlorhydria, and 4 or 5 per cent. had no hydrochloric acid, yet these persons, above or below the average, were healthy people; short or long stomachs, and a degree of acidity above or below the normal, ran in families, and no difference was found in the mucous membrane. If the 80 per cent. average people suffered from septic teeth they escaped or had only some indigestion; if persons with hyperacidity had focal infection in the mouth, a high proportion developed a duodenal ulcer. If patients with hypochlorhydria had septic foci in the mouth the microbes escaped into the intestine, owing to the absence of the disinfectant action of free hydrochloric acid. Of cases of bacillary dysentery, 25 per cent. had no free hydrochloric acid, and nearly a third of patients with appendicitis and cholecystitis were hypochlorhydriacs. This achlorhydria also predisposed to Addison's anaemia and to subacute combined degeneration of the cord. In three-fourths of the cases Addison's disease was a family disease. From this it followed that the gastric juice of the relations of a patient with Addison's disease should be examined, and if achlorhydria were found preventive measures taken. If a patient improved or recovered, relapse or recurrence was common, as the predisposition (the absence of free hydrochloric acid) was still there. In all cases of achlorhydria, free dilute hydrochloric acid should be given (2 drachms thrice daily)—one dose early in the morning on a fasting stomach, and two others with meals. The study of blood pressure, Dr. Hurst said, illustrated the same proportions: 80 per cent. of individuals had an average of 125 mm. (male) and 115 mm. (female); and the pressure was no higher at 40 than at 16, but some 3 to 5 per cent. of healthy persons had a pressure of 150 mm. (women 140) and 3 to 5 per cent. a pressure of 105 mm. An insurance company said that the best guarantee was a low blood pressure—the asthenic type; it predisposed to nothing, but the patients were more liable to suffer from fatigue. High blood pressure predisposed to changes in the arterial walls, and persons presenting it were more apt to suffer from septic foci, and from too much eating, drinking, and smoking. The symptoms were due to overwork and worry, and the toxins already mentioned. Another instance showing the importance of constitution was furnished by the predisposition of those with hyperacidity of the urine to contract nephritis in scarlatina. Of 100 patients with scarlatina, 20 had

hyperacid urine, and of these 14 developed nephritis; of the 80 of moderate or low acidity very few, and of those whose urine was systematically kept alkaline only 3 per cent., developed nephritis. Gall stones had been called a family disease; some 30 per cent. of patients gave a family history; this was due to a variation in the fat metabolism found in a certain number of persons; it tended to produce more than the average amount of cholesterol; and this excess when cholecystitis set in started the formation of gall stones. As a therapeutic deduction the yolk of eggs and cream should be debarred in any one with trouble in the gall bladder. Further illustrations were drawn from diabetics, 30 per cent. of whom were said to give a family history, and from asthmatics. People might have an idiosyncrasy for the exciting causes of asthma, but without the asthmatic constitution full asthma would not be developed; it was wrong to allow people to stay in a locality in which they were prone to be affected, and this especially held with regard to schoolboys. A boy ought not to be kept at a school where he was constantly suffering. Every asthmatic had some place where he was free, and in such a locality he should live.

A vote of thanks to Dr. Hurst, moved by Dr. Thomas House and seconded by Professor Fullerton, was passed with acclamation. In conveying it to Dr. Hurst the president said that Dr. Hurst had been elected an honorary Fellow of the society, in whose list there were now many distinguished names.

#### ROYAL VICTORIA HOSPITAL, BELFAST.

On the morning of October 29th Dr. Hurst gave two clinics at the Royal Victoria Hospital, Belfast—one on a case of pernicious anaemia, and the other on a case of achalasia of the cardiac sphincter of the stomach giving rise to enormous dilatation of the oesophagus. A large number of medical men attended, and all the students. At the end Mr. Mitchell, chairman of the medical staff, expressed the warm thanks of all present to Dr. Hurst for his clear and illuminating description of these two cases.

#### DUBLIN'S HEALTH AND BABY WEEK.

An educational health and baby week was organized in Dublin by the Women's National Health Association from October 16th to 23rd. In order that the campaign might reach every home in the city, instead of using one central hall for lectures and exhibitions, advantage was taken of the baby clubs, which are situated in the nine dispensary districts, and each club was a centre of activity during the week, special lectures, health talks, and demonstrations being given. The care of the teeth and oral hygiene was the subject of lectures at the local factories and national schools. That these lectures were very much appreciated was shown, not only by the essays which the school children wrote, but by the fact that some of the managers have asked that a course of lectures on health and hygiene should be given in the schools once a month during the winter. In the factories the management stopped work fifteen minutes before time in order that their workpeople might hear the lectures, and the workers voluntarily remained over time. The local authorities arranged for health talks in the public libraries during the week, and they also distributed leaflets. The week opened on Saturday, October 16th, with a display of folk-dancing by the children in the playgrounds. On Monday, at the Rotary Club, Mr. E. P. McCarron, Secretary to the Local Government Department, spoke on public health as affecting the State, and in the afternoon Dr. Falvey lectured on "What to do before the doctor comes." In the evening Mrs. Russell, M.B., broadcasted an address on public health. On Tuesday, in No. 1 West Dispensary District, violet-ray demonstrations were given, and great interest was shown in the lecture on artificial sunlight by Dr. Maurice Hayes. In the No. 1 East Dispensary District Mrs. Fegan Redmond lectured on vitamins, while in the No. 4 South City Dr. Alfred Boyd gave an interesting lecture on child welfare, which was followed by a lecture on Italian cities by Dr. Frank Dunne. On Wednesday, in No. 2 East, Dr. H. MacAuley gave a lecture on the open-air treatment of surgical tuber-

culosis. Dr. Stephenson, Dr. Lombard Murphy, Sir William Thompson, and Dr. Hennessy spoke of the advantages of open-air treatment as provided at Cappagh and Leysin. At Inchicore Dr. P. J. Keogh and Dr. Healy lectured on care of the mother and child, and Dr. McAreevey gave a special talk on the care of the eyes in school children. Miss Keogh, welfare superintendent in the factories of W. D. and H. O. Wills, gave her experience of the benefit of welfare centres to employers. On Thursday, at No. 2 South City, Dr. Freeman gave a talk on vitamins, and Dr. Crichton and Dr. Solomons lectured on the care of the mother and the child. On the same day, at No. 1 South City, Dr. Magennis, Dr. Keogh, and Dr. Keelan lectured to a large audience on child welfare. On Friday, at No. 3 South City, Dr. Devane gave a lecture on the care of the skin, and Dr. Gaffikin spoke on the school child. The week ended on Saturday with a health exhibition and demonstrations at the Mansion House. There was an afternoon lecture for the child welfare centres of County Dublin, and in the evening a public meeting, at which Mr. McCarron presided, and the principal speakers were Dr. Prudence Gaffikin, Dr. Hennessy, T.D., and Mr. Commissioner Murphy. At the end of the meeting prizes were awarded to the school children who wrote the best essays and to the babies who had come cleanest to the baby clubs during September. A prize is to be awarded subsequently to the mother who writes the best account of what she learnt during baby week.

## Correspondence.

### GOOD AND BAD DIETS.

#### *The Diabetic Diet.*

SIR,—In connexion with the recent contributions to the JOURNAL by Colonel McCarrison and Dr. Harry Campbell on "good" and "bad" diets in modern life, some of the effects noticed in the dietetic treatment of diabetes would seem to be strong evidence in support of their arguments. No one would, of course, advocate the diabetic as the ideal diet, but some of the effects of the adoption of a diabetic diet, apart from the amelioration of carbohydrate metabolism, point a lesson of importance to normal individuals.

The diabetic diet is the antithesis of the usual modern "bad" diet, which is composed so largely of soft, concentrated carbohydrate foods, such as bread, which are entirely absorbed in the small intestine. The diabetic diet, on the other hand, consists largely of bulky vegetables, which leave a large residue in the intestines, and extras, such as bran biscuits and agar jellies, which pass unchanged through the alimentary tract, are often added as a sop to appetite.

After the adoption of a typical diabetic diet, it is very rare to find any digestive trouble. The change is most noticeable in patients who have suffered from dyspepsia or constipation for many years before the development of diabetes, and in whom these symptoms were therefore not due to diabetes. In a short time they are able to eat anything, and rough and bulky vegetables and "heavy" meats, which previously gave them dyspepsia, cease to trouble them at all. Their appetites are excellent, and they usually eat a far bulkier diet than before without inconvenience and with relish. Most of these patients probably eat at least one pound of green vegetables a day. One of my patients who is allowed 15 grams of carbohydrate for breakfast insists on taking it all as vegetables, and starts the day with 18 oz. of cabbage along with his bacon and egg! This is as close an approximation to the pre-agricultural diet of primitive man, to which Dr. Campbell drew attention, as modern man is ever likely to tolerate. I have never seen the constipation of a lifetime able to withstand such a diet.

It seems impossible to say whether this improvement in digestive power is due to the mere bulk of the food or to its richness in vitamins, particularly vitamin B, whose deficiency has been blamed for intestinal atony. I incline to the former view, because many severe diabetics eat no

fresh fruit, and in winter their vegetables are practically all cooked, and yet they suffer from no signs of intestinal stasis. Another factor which may be important in improving the digestion of these diabetics is the reduction of the total calories in their diet, with the result that their metabolism never suffers from a surfeit of food. When the digestive tract is offered little, it seems to make the most of it.

Be this as it may, it appears that the diabetic diet has some points about it which may be applied with advantage to the normal individual.—I am, etc.,

London, W.1, Oct. 30th.

R. D. LAWRENCE.

### THE IMPROVEMENT OF HEALTH WEEK EXHIBITIONS.

SIR,—I quite agree with the protest made by Dr. Burton in your issue of October 23rd (p. 760) concerning the introduction of the commercial element into exhibitions promoted by public health committees.

The sole object of these exhibitions should be educational; there should be no solicitation to buy or even to try a sample, and if space is sold to trading concerns this is inevitable. The only excuse for the admission of the commercial stall is to pay for the hire of the hall and other expenses. I submit that it would be preferable to defer the holding of a health exhibition until the money to make it a real one is available.

I have been associated with several health exhibitions, in all of which each exhibit was selected with a view to demonstrating some item of practical importance to the health of a working-class (or indeed any other) family. No space was sold; no samples were given away; good advice was given, nothing else, except in some cases a leaflet on some point concerned with health; nothing was sold except booklets on health for those who asked for them.

At one such health week which finished on Saturday, October 23rd, the attendances in seven days numbered 43,667. This shows that the public appreciate, and will attend, an exhibition which is purely educational.—I am, etc.,

Hull, Oct. 25th.

W. ALLEN DALEY.

SIR,—The letter in your issue of October 23rd (p. 760) from Dr. Burton, medical officer of health, Ilford, on the above subject, opens a matter which I considered in a paper given on July 6th of this year at the Mansion House conference of representatives of sanitary authorities held in connexion with the Royal Sanitary Institute Congress, from which I quote:

"Prominent firms are quite willing to exhibit at such an exhibition, but of course it must be a *sine qua non* that the exhibition takes the form of an educational exhibition, and such firms are frequently quite willing to contribute according to the space occupied by them for their stand. This, of course, may very materially reduce the cost to the local authority. . . . It is, however, in respect of the assistance which may be drawn upon that care must be exercised. A generation ago there was a famous political satire, a story by name "Ginx's Baby," which depicted the use made of the working man by political parties. Likewise at the present day one might state that public health propaganda is becoming a "Ginx's Baby." It is used by insurance companies, who issue leaflets for distribution; pseudo health visitors visit from door to door, ultimately recommending some proprietary food or other article. It is because of these activities that the careful choosing of the exhibits accepted for health week or other exhibitions must be an important factor, and unless this is done judiciously the public will be unable to distinguish between the reasoned, well-balanced advice on health and the mass of camouflaged advertising propaganda with which the country is at present flooded."

I have noticed in the extracts from the paper which have been published so far that the warning and criticism part was generally omitted, while the practical aspects—for instance, the sources for material—were, perhaps quite naturally, given fairly fully. It may be that the income derived from the contributions of exhibitors and the reduction of expenses overshadow the care which must be exercised in the choice of exhibits, and the necessity for the health department of the local authority bringing into prominence their own health propaganda and arranging exhibits, demonstrations, and lectures directly in connexion therewith.

In 1921, building on my experience previously with such exhibitions, I arranged for one that year in Deptford, but while allocating free space in the hall to approved exhibitors, who were carefully chosen, these were allowed, still under such approval, to provide their own stands, but did not contribute in any other way. The control, therefore, was firm, and the public health department also provided exhibitions on diet, etc., and demonstrations, as well as lectures.

The whole point in my mind is one of adequate control by the medical officer of health.—I am, etc.,

G. CLARK TROTTER,  
Medical Officer of Health, Metropolitan  
Borough of Islington.

October 29th.

### PERSISTENCE OF TUBERCLE BACILLI IN BUTTER FROM TUBERCULOUS MILK.

SIR,—The opening observation of Dr. Cookson, the bacteriologist to the Sunderland sanitary authority, in his article published in your issue of October 9th (p. 637), is correct, but only states the case very gently and mildly. The danger due to the presence of tubercle bacilli in butter is only less than the danger arising from their presence in milk and cream.

Dr. Cookson does not seem to be aware of the work done on the subject on behalf of the United States Bureau of Animal Industry many years ago, and continued over a period of years—at least he does not make any reference to the investigation. One of the workers for the Federal Government—Dr. Schroeder—came to the conclusion that:

"Tubercle bacilli in milk are transferred to the cream, butter, and cheese made from it, and may occur in these products in greater concentration than they had in the milk from which they were derived."

And in April, 1910, the Bureau of Animal Industry reported that:

"The testing of infected butter has been continued, and in the later experiments of this nature the conclusions reached through former work have been confirmed. Tubercle bacilli will retain their vitality and virulence while in butter under common market conditions for at least five months."

(I may mention incidentally that typhoid bacilli also were demonstrated, in the course of the same investigation, to persist in butter for 151 days.)

I hope Dr. Cookson will forgive me if I suggest that when he next publishes an article, he read it over, with a view to making sure that he has written with precision and with lucidity. I experience a difficulty in understanding just what he means by the phrase "specimens of milk were collected from five tuberculous cows; three of these cows were afterwards shown to have extensive tuberculous lesions." I think I can guess what he wishes to express, but on first reading one wonders why he needs to state that three out of five tuberculous cows were tuberculous. I really do not know what he wishes to convey by the fourth paragraph in his article.

From Dr. Cookson's description of his experiments one is led to surmise that he is not *au fait* with the modern significance of the term "pasteurization" when it is applied to milk. He states that he heated samples at 55°, 60°, 70° C., and ingeniously describes careful stirring of the samples for thirty minutes, while the thermometer readings were carefully watched. Fifty degrees Centigrade (131° F.) is far below, and even 60° C. (140° F.) is below, the recognized minimum pasteurization temperature, whilst 70° C. (158° F.) is too high.

Pasteurization of milk involves its heating to a determined temperature, in closed vessels, for the appropriate period—most commonly 62.7° C. (145° F.) for thirty minutes—thereafter immediately cooling it to under 40° F., bottling it, and sealing the bottle. The freedom of milk, so treated, from tubercle, and all other pathogenic bacteria, has been demonstrated on innumerable occasions during the past thirty years, both by exact scientific experiments and by practical experience. The vital statistics of those cities in the United States where the very reasonable and moderate requirement is made that all milk sold for human consumption shall be safe—that is to say, either pure and

free from dirt and pathogenic bacteria if sold raw, or, in the alternative, pasteurized—are quite convincing. It is regrettable that so many people write, and speak, on this subject with inadequate information. The best modern dairy companies purchase the cleanest milk which they can obtain—and they pay more for clean milk than for less clean milk—and then they proceed to pasteurize it. Pasteurization is not intended to be a substitute for cleanliness, but it is a complementary measure. Even certified milk is always liable to contamination from human sources whilst being handled, as well as to that from tubercle bacilli arising from kine which have developed tuberculosis in the long interval of six months permitted between tests.

After reading the description of such crude experiments as Dr. Cookson describes; after learning from him that butter was made by using a "starter," with no reference to any test of the latter for freedom from bacilli, one is by no means surprised to learn that he came to the erroneous conclusion that pasteurization is not always a sufficient protection against the survival of tubercle bacilli, although one must demur at his description of his experiments as most careful pasteurization.—I am, etc.,

October 14th.

S. G. MOORE, M.D.,  
Medical Officer of Health, Huddersfield.

## SANATORIUM TREATMENT.

SIR,—I do not think that any careful reader of my letter (*BRITISH MEDICAL JOURNAL*, September 25th, p. 578) would find in it—as Dr. Stocks avers—a suggestion that "diagnosis without bacilli is valueless." It would be absurd to make such a suggestion. But to say of 2,794 consecutive cases of pulmonary tuberculosis that they were all cases of "undoubted" pulmonary tuberculosis, while admitting that "the number of cases in which bacilli were sought for and found" was as small as that stated in Dr. Stocks's statistics, is to leave out of account the effect of the personal factor in diagnosis. What might appear sufficient for a positive diagnosis of incipient disease to one observer would be held to be quite inconclusive evidence by another. This difference in the personal factor is well illustrated by the letter of Dr. E. E. Prest in the same issue of the *BRITISH MEDICAL JOURNAL*, to which Dr. Stocks himself alludes. Dr. Prest maintains that the diagnosis of tuberculosis "should be made by a study of the history of the patient and a careful inquiry into symptoms, and not by the presence of physical signs and the finding of tubercle bacilli in the sputum." (The italics are mine.) If this advice is followed, I make bold to say that the percentage of cases which would be wrongly diagnosed as tuberculous would be very considerable, and that any statistics based on figures so obtained would be valueless.

No group of symptoms is pathognomonic of pulmonary tuberculosis, but the presence of certain symptoms together with certain physical signs is practically diagnostic of the disease. To divorce the one from the other is inadmissible. Dr. Prest's system may perhaps result in the cure of some early cases which are thus taken in good time, but against this there have to be balanced some dangers which were very fully discussed in a recent correspondence in the *BRITISH MEDICAL JOURNAL* on "Common sense in relation to doubtful tuberculosis" (February and March).

In previous statistical studies (for example, those published by the King Edward VII Sanatorium) it will be found that separate tables are given for "sputum-positive" and "sputum-negative" cases, and the necessity for this has been generally recognized.

Dr. Stocks puts the question, "Had we not better frankly admit that there are small hopes indeed that any large group of patients are ever likely to be persuaded to spend more than an average of six months in a municipal sanatorium?" I cannot say what is the average length of stay in the Cheshire Joint Sanatorium, but I can say that a considerable proportion of patients sent in by me are retained for a period exceeding six months. To make a practice of sending patients to sanatoriums for a period of three months only was, I had hoped, a relic of the past in any well organized tuberculosis scheme.—I am, etc.,

Alderley Edge, Cheshire, Oct. 17th.

E. WEATHERHEAD.

## PREVENTION OF CORYZA.

SIR,—A recent article in a lay periodical about winter colds seems to me to be characteristic of many other articles of this type in being slipshod, while its directions are loose, indefinite, and might do harm. Toilet of the nostrils with soap and water is advised, but the author's conclusions as to the mode of action of the remedy are, in my opinion, quite incorrect. For fourteen years I have steadily advocated the use of soap as an almost certain preventive of "colds," if used regularly; it is also the most valuable part of the treatment for an established "cold." (I do not use "cold" vaccines, as they are apt to weaken the myocardium for long periods—due to the toxin of *M. catarrhalis*, I believe.)

As a preventive I advise patients to get a rather thicker soap lather than usual on the hands when washing, and smear it over the face in the usual way, but, further, to rub the lather across the nostrils half a dozen times or so, but not to attempt to push any up the nostrils, nor to sniff it up. They should then proceed to wash the upper part of the face with warm water, and then gently throw several handfuls of the water against the openings of the nostrils—again without sniffing. Then blow the nose, one side at a time, with the finger and thumb, when it will be found that quite a quantity of mucus, inspissated and fresh, mixed with dust and debris, will easily come away. Finally, swill off with a little warm water. When a person already has a "cold" in the nose the above method, along with a few tablets of aceto-salicylic acid, taken at intervals after food, will soon clear up the generalities of "colds" in a normal nose. If there is sore throat as well, then, in addition, a few formalin tablets are a great help. In persons who already have a "cold," their nasal, and often the pharyngeal, mucous membranes are already damaged, and the soap treatment does better with the additional remedies I have mentioned. I consider that all schools and works, and indeed the community generally, should be urged by the Ministry of Health to attend to this very simple measure as a routine for the prevention of "colds," which, in the aggregate, inflict an immense loss on the country. The soap should be good "toilet soap," not common soap containing free alkali. This latter soap injures the skin and so would injure the entrance to the nares, which is lined with skin. In the method I have described this is the only area touched by the lather, so that the soap does not act as an antiseptic, except at the very entrance to the nose, and this is unimportant, as water would do equally well almost. The rationale of the treatment is that the posterior and upper regions of the nose are normally sterile, and that it is better to wash the nose out from above downwards on this account, rather than from below upwards. The soap method thus does away with the certainty of microbes being carried into the upper regions, and also saves the delicate nasal mucous membrane from the insult of coming into contact with "foreign" antiseptics, which both occur with douches, sprays, and sniffing up the nose from the palm of the hand. This latter, by the way, is still advised to out-patients at nose and throat clinics.

The soap lather, used as recommended, stimulates the ciliated and globular nasal epithelium (and causes a flow of mucus from above downwards) reflexly through the terminations of the fifth nerve at the entrance to the nose. Further, the lacrymal glands are stimulated also, through the branch from the ophthalmic division of the fifth nerve which goes to the tip of the nose. This combined flow of mucus and lacrymal secretion, aided by forced expiratory efforts, cleans the nose effectively and safely, in a very short time, and in a very simple manner, so that a child can be readily taught to make a habit of it. The nasal mucus itself is antiseptic, and the increased flow deals with any remaining microbes by inhibiting (or possibly destroying) them, and neutralizing or weakening their toxins. In my long experience of this treatment I have found that if a person is not speedily benefited by it, further diseases are present, or there is need for rhinological surgery.—I am, etc.,

ANDREW S. McNEIL, L.R.C.P. and S.Ed.

Liverpool, Oct. 20th.

# BRITISH CHEMICAL RESEARCH.

SIR.—The recent merging of the outstanding British chemical companies into a single organization is hailed by scientific men as one of the greatest steps towards the economic prosperity of the chemical industry. For the first time in history, Britain will be able to bring to bear upon the problems of organic chemical research an adequate organization, and it would be an impertinence on my part to discuss in this connexion the general questions of research in industry. There is, however, one aspect of the question to which I would like to draw particular attention—namely, the application of research to medicinal and therapeutic organic chemicals.

The last twenty or thirty years have seen the advance of medicine in the direction of accurate recognition of the nature of disease, and the discovery of the infective agents causing it. While there is, undoubtedly, an economic advantage to be derived from the prosperity and advance of huge commercial organizations, one of their fundamental duties to humanity lies unfulfilled if disease and suffering are left for their suppression to the chance efforts of isolated investigators. Many diseases—syphilis, tuberculosis, malaria, sleeping sickness, to mention only a few—are among the scourges which exact an untold tribute of misery from millions every year, and although the cause of these troubles is accurately known, in only a few cases is any selective drug available. It cannot be too strongly insisted upon that the present condition is one which need not endure. Whilst congratulating the German investigators upon their achievement which has culminated in the introduction of drugs of the type of salvarsan and Bayer 205, we may envy the facilities and resources upon which they are able to draw; it should be realized that there is now no obstacle in the way of establishing such facilities for ourselves, and, quite apart from commercial rivalry, it should be a question of honour with us to push on in the same direction in an effort to free humanity from some of its scourges. In this connexion, too, I would recall the words of the president of the American Chemical Society:

“... synthetic organic chemistry will prove itself to be, perhaps, the most potent factor of all those that are working towards the advancement of civilization and the peace of the world. I refer to the use of chemical compounds in combating disease and, as a result, prolonging life... the modern science of chemotherapy... Malaria, spread in the most fruitful part of the globe, is incapacitating and destroying millions, and we have used but one drug—quinine—to fight it.”

Thus, not only are British human resources concerned, but the whole untapped resources of Empire, now locked up by the spectres of malaria and sleeping sickness, might be released.

What is needed is the vision and broadmindedness of a commercial organization, such as that just formed, that will make possible the formation of a band of synthetic organic chemists, biochemists, and medical men, who, freed from the trammels of routine, will be able to work together upon chemotherapeutic problems. More, also, is necessary; the men concerned must be able, not only to place their hands upon every known compound, process, and method of treatment, but they must also be able to appreciate the difficulties of each other's craft. The medical men must realize that the task of building up the necessarily complex substances which alone seem to have therapeutic value is a matter for careful thought and patient experiment; the chemists must realize the intense difficulties of obtaining and correlating medical and clinical data, and, above all, the commercial organization which endows such a product must be prepared to wait, not months, but years for the fruitful results which must of necessity arise from such a combination of resources.

Finally, it appears to me to be a cogent argument that if, for economic reasons, the cotton industry found itself able to finance research on textiles, then the chemical industry should, for humanitarian reasons, finance research for the full utilization of the resources of chemistry.—I am, etc.,

ARNOLD RENSHAW, M.D.

Laboratory of Applied Pathology and Preventive Medicine, Manchester, Oct. 29th.

# Obituary.

FRANCIS WARNER, M.D., F.R.C.P.,  
Consulting Physician to the London Hospital.

WE have to announce with regret the death, on October 26th, in his eightieth year, of Dr. Francis Warner. He was one of the first to enter on a field of clinical research, which has since been very assiduously cultivated. He was physician to the East London Hospital for Children at Shadwell, as well as to the London Hospital, and at an early stage of his career he began to devote much of his time and energies to establishing a system by which the physical and mental defects of children might be scientifically estimated and recorded.

He received his medical education at King's College Hospital and graduated M.B.Lond. in 1872; in the following year he took the M.D. degree and became F.R.C.S.Eng. He was appointed medical registrar of the London Hospital in 1877, and assistant physician in 1879. In 1883 he was elected a Fellow of the Royal College of Physicians of London. He published a number of books and essays on his favourite subject, including works on the study of children and on the nervous system of the child. During the years 1893-96 he undertook a laborious investigation of the mental condition of some hundred thousand children in 106 schools; his results were published in the *Journal of the Royal Statistical Society*. In 1896 he wrote *The Children: How to Study Them*, and two years later made another contribution to this subject under the title *The Study of Children*. In 1887 he described his methods and researches in a Hunterian Lecture at the Royal College of Surgeons of England, and in 1892 gave the Milroy Lectures before the Royal College of Physicians of London. In them he described the methods and results of an inquiry as to the physical and mental condition of school children. In 1889 he had given evidence before the Royal Commission on Blind, Deaf, and Defective Children; the report of this Commission led to the passage of the Act which enabled the London School Board to provide special schools. In addition he made reports at various times to the Local Government Board, the Home Office, and the Education Department, on the condition of children for whose care and education these departments were responsible.

Dr. Warner retired from practice some years ago and the present generation knew very little of him; but he was a well known figure in London in the last twenty years of the nineteenth century, and was very greatly liked and respected by his fellow practitioners, although few thoroughly appreciated the importance of the pioneer work he was doing.

FRANK H. BARENDT, M.D.LOND., F.R.C.S.Eng.,  
Physician, Skin Department, Royal Southern Hospital,  
Liverpool.

WE have to record with great regret the sudden death at his home in Rodney Street, Liverpool, on the morning of Thursday, October 28th, of Dr. F. H. Barendt, the well known dermatologist.

Frank Hugh Barendt, the third son of J. H. Barendt, was born in Liverpool in 1861, and received his early education at Liverpool College (of which he later became a life governor) and St. Petri School, Danzig. At an early age he decided to follow the profession of medicine, and on leaving school in 1879 entered the University of Liverpool, where he had a distinguished student career, winning the Roger Lyon Jones scholarship in pathology, a subject which always attracted him. In 1885 he obtained the M.R.C.S. and L.R.C.P. diplomas; in 1887 he graduated M.B.Lond. with honours in materia medica, and in the following year proceeded M.D. He became a Fellow of the Royal College of Surgeons of England in 1890. After obtaining his first qualifications he travelled and studied for some time in France, Germany, and Austria, working in the Universities of Vienna and Berlin under Hebra, Kaposi, Neumann, Max Joseph, and Lassar. On returning to Liverpool he served as house-physician at the Royal Infirmary, senior medical officer to the Bootle

Borough Hospital, and assistant medical officer to the Rainhill Mental Hospital. When he had completed these appointments Dr. Barendt finally made up his mind to specialize in dermatology. He was appointed honorary surgeon to St. George's Hospital for Diseases of the Skin, Liverpool, and this was followed by election to the post of physician to the department of diseases of the skin at the Royal Southern Hospital. These two posts he filled with great acceptance until his death; he held appointments also as dermatologist to many homes for children in Liverpool. When the British Medical Association held its annual meeting in Brighton in 1913 he was vice-president of the Section of Dermatology, and he had been one of the local general secretaries at the Liverpool meeting in the previous year.

With a wide knowledge of his subject Dr. Barendt combined the power of clear and accurate exposition, and his literary skill found expression in numerous monographs on dermatology and venereal disease. Among these a paper in lighter vein on "Soap, its use, misuse, and abuse," which appeared in 1917, was reprinted in America and Australia. An article published in our columns in 1920, on scleroderma, is a good example of his writing; it reveals his scholarly approach to a medical subject and his attention to detail. In it he wrote: "There is a real danger that in coining new terms we may be misled to regard them as new knowledge. A great advantage would accrue to us if a short course on the history of medicine were instituted in our university. Nosological nomenclature alone would play an interesting part in such a subject." The subject, however, that perhaps interested him most was the diagnosis and treatment of syphilis. He was one of the first practitioners in Liverpool to make use of intravenous injections of arsenical compounds, and was officially appointed by the Carnarvon and Anglesey health authorities to take charge of the special venereal disease clinic at Bangor. In this work he laid special stress on the need for examining every case minutely and not depending merely on a laboratory diagnosis.

Dr. Barendt was interested in all European languages, and spoke French, German, and Russian, and his services as a translator were often called for. He was an enthusiastic member of the Liverpool Medico-Literary Society, before which he often read papers, and served on the committee of the local Czecho-Slovakian Society; he had held many offices also in the Liverpool Medical Institution, and had been editor of the *Liverpool Medico-Chirurgical Journal*. For some years he acted as the *Liverpool Correspondent* of the *BRITISH MEDICAL JOURNAL*, and could always be depended on for practical help at short notice, whatever might be the other claims upon his time. In this work his thoroughness and regard for accuracy were conspicuous. So it was, too, in his private and professional life: he shone most in matters of detail, and by countless little attentions won the esteem and affection of all who came to know him.

Dr. Barendt is survived by his widow—a daughter of the late Dr. Crowe of Liverpool—three sons, and two daughters. The eldest son died in 1918; the second is studying medicine in London.

For the following appreciation we are indebted to Sir JAMES BARR:

The death of Dr. Frank Barendt has removed a very prominent figure from medical circles in Liverpool, a valued correspondent of the *BRITISH MEDICAL JOURNAL*, and personally I feel the severance of an unbroken friendship of nearly forty years. He was an excellent linguist, a great authority on orthography and etymology, so that when Barendt had expressed his views on any such point there were very few who would attempt to controvert him. As a classical scholar he had few rivals and fewer equals in the medical profession. He was a cultured gentleman in literature, but I can scarcely add in art, as his tastes were of a very modest character. He was a keen controversialist, and stuck to his views with great pertinacity, though he was always tolerant of those who differed from him. We often agreed to differ rather than bring a disputed point to a final conclusion.

He was a man of wide sympathies, and had he had the means I have no doubt those sympathies would have been freely and tangibly expressed. He had deep religious feelings, which were never paraded for public inspection, and he made no attempt to thrust his convictions on others. His German extraction often showed itself in his attention to the most minute details, so that he was apt to miss the wood for the trees. In scientific work he was an excellent researcher, but failed to correlate the work of others, and could never become a discoverer.

He had a very happy domestic life, except for some losses in his family, and he felt very acutely the early death of a son who gave promise of a brilliant career. Even in adverse circumstances he was always bright and cheerful. He could never afford the luxury of being ill, though it would now appear that in the preservation of health he must have neglected the prevention of disease. Little did I think when I recently received his congratulations that within ten days I should be writing his obituary notice. Dr. Barendt might have been considered an expert writer of obituary notices, and those from his pen which appeared in the *BRITISH MEDICAL JOURNAL* were always faithful representations of the characters portrayed, without any excessive colouring, and any failings were gently glossed over. He adhered to the adage, *De mortuis nil nisi bonum*. With him it is not now a question of *requiescat in pace*, but let his good work blazon forth and his memory be ever kept green by those who knew him. My deep sympathy goes out to his widow and family.

A COLLEAGUE closely acquainted with Dr. Barendt's work writes:

His knowledge of his specialty was profound, and his opinion was much valued. He wrote much on his subject, and these articles, as well as his numerous papers read before the Liverpool Medical Institution, were all characterized by sound clinical observation and a rich knowledge of the literature. At the clinical meetings of the Institution he could always be relied upon to show some rare and interesting cases, and he counted no trouble too great to make these demonstrations successful. He was an excellent teacher, and students followed his clinics with interest and profit. Carefully trained in the old school of Vienna dermatology, he recognized that treatment was, from the patient's point of view, the most important side of dermatology. His treatment was never empirical, but was based on pathology, and his success in this was great. His mature judgement saved him from the too early and indiscriminate adoption of every new and vaunted remedy; but when assured that there was good in any remedial agent he let his patients have the benefit of it. But he never allowed his appreciation for a new remedy to blind him to the virtues of the old. This attitude of mind largely contributed to his success in treatment, and to the high opinion he won from his professional colleagues. But it was for other qualities besides his great abilities as a skin specialist that he was so much beloved. He was gifted with a genial spirit and a quiet sense of humour that made him the pleasantest of companions. Kindnesses large and small were done daily by Dr. Barendt, and many a young member of the profession has had reason to feel deeply grateful to him, not only for professional help, but also for sound advice on some of those difficulties that beset the path of the newly fledged practitioner. A devoted father, he found his greatest happiness in his family circle, or in the company of a few chosen friends. He was universally liked, even by those who differed from him profoundly on professional matters or in politics. In a material age he preserved a cheerful idealism. The pursuit of wealth for its own sake, or the wild race for position or power, meant nothing to him. His aim was to serve his day and generation faithfully, and few men have achieved that ambition so completely. He will be greatly missed in Liverpool by a large circle of patients, rich and poor, and by all his professional colleagues. It seems only fitting that one who loved the classics should have a Latin epitaph. There are many that spring to mind—each in its way appropriate—but for him a timeworn one seems best, for of Barendt it was wholly true: *Integer vitae, scelerisque purus*.

# THOMAS CHURTON, M.D.,

Consulting Physician, Leeds General Infirmary.

We have to record with great regret the death, at the advanced age of 87, of Dr. Thomas Churton of Leeds. Born at Stafford in June, 1839, Dr. Churton lost his father during his infancy. His mother became matron of the old General Infirmary at Leeds, and the high character of her work is still remembered there. He was educated at Shrewsbury and subsequently at Leeds, where he entered on his medical curriculum and became a junior resident assistant at the Infirmary. After becoming M.R.C.S. he was for some years in private practice at Erith in Kent. During this period he spent a great amount of time in paying frequent visits to London, where he attended the practice of Guy's Hospital. He then threw up his general practice and went to Aberdeen, where he spent a year in most close and assiduous study, graduating M.B., C.M. in 1876, under the conditions which then prevailed, and proceeding to the degree of M.D. in 1877. Of this time in his life the writer of this notice, himself an Aberdeen man, has very often heard him speak with the greatest pleasure. He made many friends, and used to laugh at them when he was told that his bold expressions of determination to come back and see them all once more would come to nothing, though he had to confess that they were right.

Soon after settling in Leeds he was, in 1879, elected honorary physician to the Infirmary, having as his two senior colleagues the late Sir Clifford Allbutt and Dr. John Eddison, who now lives in retirement at Cuckfield, Sussex. At that time there were no assistant physicians, and Dr. Churton was unsparing in his work, not only in the wards, but in the out-patient room and in the post-mortem department. When Dr. Eddison retired from the full staff in 1892 Dr. Churton became senior physician, and he held this position till 1919, when he became a member of the consulting staff. He thus served the Infirmary in an honorary capacity for the long period of forty years. He was for many years on the staff of the Leeds Public Dispensary, and served the old Leeds House of Recovery as well as other charitable institutions. He was lecturer on medicine at the Yorkshire College when it was one of the constituent colleges of the Victoria University.

By many generations of Leeds students Dr. Churton will be remembered as a man of the greatest charm of manner and as having one of the most delightful of voices and one of the most infectious of laughs. His diligence and conscientiousness were beyond all praise, and his clinical investigations were carried out with unsparing zeal. If it has to be stated that his zeal sometimes outran his discretion and perhaps exhausted the patience of his colleagues, this can be put on record without in any way detracting from the high esteem and affection in which he was held by all.

Dr. Churton took great interest in the work of the British Medical Association: he was honorary secretary of the Leeds Division and representative in the Representative Body in 1903, vice-chairman in 1905-06, chairman in 1907, and a member of the Executive Committee for 1909-13. He was a member of the Council of the Yorkshire Branch for 1896-1908, was elected president of the Branch for 1912, and became vice-president in 1915.

Dr. Churton was a man of wide general culture, well read, and a charming conversationalist; he will long be held in affectionate remembrance by the profession in Leeds.

After prolonged ill health Dr. DAVID LLOYD, J.P., died at Denbigh, North Wales, on October 23rd, in his sixty-second year. Dr. Lloyd was educated at Ruthin Grammar School, Glasgow University, and the Middlesex Hospital; he graduated M.B., C.M.Glasg. in 1891. After practising for some time in South Wales he settled in Denbigh in 1892, where he built up a large practice and became very popular. His numerous appointments included those of medical officer of health to the borough of Denbigh and medical officer to Howell's School, Denbigh, honorary surgeon to the Denbighshire Infirmary, consulting surgeon to King Edward's Memorial Association, a member of the court of governors of University College of North Wales, and medical officer to the police force. He was a member, and for some time an alderman, of the Denbighshire County Council, which he represented on the board of

governors of the North Wales Counties Lunatic Asylum, Denbigh. He was a justice of the peace of the borough and county of Denbigh, and mayor from 1903 to 1905. Notwithstanding the many claims upon his time, he managed to attend post-graduate classes in Liverpool University and pay weekly visits to the Liverpool hospitals for special study. He interested himself actively in the progress of the North Wales Branch of the British Medical Association, being chairman of the Denbigh and Flint Division in 1912, a member of the North Wales Branch Council from 1911 to 1923, and president of the North Wales Branch in 1915. His death will be keenly felt by a very large number of friends and patients throughout North Wales. He leaves a widow but no children.

The death occurred at Birmingham, on October 16th, of Dr. JAMES HUGH SPROAT, in his sixtieth year. Dr. Sproat received his medical education at Queen's College, Birmingham, where he obtained the diplomas L.S.A. in 1891, M.R.C.S., L.R.C.P. in 1892, and graduated M.B.Lond. in 1893. After holding appointments as clinical assistant to the Birmingham City Asylum, assistant medical officer to the Exeter City Asylum, and senior assistant medical officer to the Somerset and Bath Asylum, he practised in North Birmingham for twenty-one years, and retired two months ago on account of ill health. He held the appointment of medical officer to the Jaffray branch of the Birmingham General Hospital for eleven years. He took an active interest in National Health Insurance from its commencement, and served as a member of both the Panel and Insurance Committees in Birmingham. He was a member of the British Medical Association and an honorary member of the St. John Ambulance Association. He married in 1912, and leaves a widow.

The death occurred on October 13th of Dr. CHARLES STENNETT REDMOND, in his eighty-fourth year. Dr. Redmond entered the Catholic University, Dublin, in 1856, and after being a scholar and exhibitor of the university he obtained the diplomas L.R.C.P.I. and L.R.C.S.I. in 1864. He then became resident medical officer of the Jervis Street Hospital, Dublin, and later, as surgeon to the P. and O. Steamship Company, spent three years in India. From 1871 to 1874 he was resident medical officer of the Gateshead-on-Tyne Dispensary, and in 1876 started private practice in that town, taking particular interest in the correction of improper feeding of young children, and, as a member of the Gateshead School Board, in improving the existing types of schools. He subsequently practised in London and Manchester. From 1918 to 1919 he was resident medical officer of the Trafford Hall Red Cross Hospital, Manchester, and when the hospital was closed he retired and went to live in Queen's County, Ireland. When the National University of Ireland was constituted he was granted the degree of M.D. *honoris causa*, as being the oldest survivor of the former Catholic University of Ireland. In 1886 he published a book on *Infant Feeding and Management*, and contributed many papers to medical journals on the diagnosis of scarlet fever, the treatment of infantile convulsions, and the cool-bath treatment of enteric fever. For many years he was a member of the British Medical Association. He is survived by his widow, three sons, and four daughters; his eldest son is a member of the medical profession.

We regret to announce the death, on October 7th, of Professor EMIL KRAEPELIN, who did so much to advance the scientific study of psychiatry. His seventieth birthday was celebrated only last February by his many distinguished pupils. During the last year of his life he had been occupied in arranging for the erection of a home for the German Psychiatric Research Institute, and in preparing the ninth edition of his well known textbook.

The deaths of the following well known foreign medical men have recently occurred: Dr. MARIA PARHOV of Jassy, a leading Rumanian neurologist and biologist; Dr. S. I. FEDYNSKY, professor of diseases of infants in the University of Moscow, and Professor SALOMON EHLMANN, the Viennese dermatologist.

## Medico-Legal.

### TWO MEDICAL MEN CHARGED WITH MURDER.

A CORONER'S jury, at Bamber Bridge, near Preston, on October 29th, after an hour's retirement following an inquiry lasting two days into the death of Norah Elizabeth Marmion, aged 24, the daughter of a Penmaenmawr quarry owner, found that the deceased died from shock caused by criminal abortion performed by Dr. Arthur Stuart Holden and Dr. Frederick Langton Webster, and that Mrs. Constance Mary Holden and Major William Edward Blackburne and Mrs. Helen Blackburne were aware that criminal abortion was being meditated.

Thereupon the two medical men were charged with murder, and the other three persons with being accessories, all being committed for trial on a coroner's warrant at the next Manchester Assizes. In answer to the charge, Dr. Holden said: "I am not guilty of any such charge"; Dr. Webster said he had nothing to say; Mrs. Holden and Major Blackburne both said "I am not guilty."

It appeared that the deceased left the home of her sister at West Cliff, Preston, on October 7th, presumably to play bridge at Dr. Webster's house at Bamber Bridge, and later the same night Dr. Webster informed the police of her death, stating: "Dr. Holden has had an operation on a lady at my house to-night, and she has died under the anaesthetic."

Mrs. Elizabeth Smith, in her evidence, said she did the cooking and her husband cleaned the surgery at Dr. Webster's house. On October 7th she retired to bed shortly before 8 o'clock because she was not well. Dr. Webster being in his surgery with some patients at the time. She overslept the next morning, and on going downstairs at 11.30 a.m. she saw a note on the door of the telephone room in Dr. Webster's handwriting: "Smith, do not go in without consulting me." Her husband said to her: "Don't go in that room; there's a woman dead in it."

Alexander French, a single man, employed with a firm of sanitary engineers at Liverpool, in his evidence, said about twelve months ago the deceased told him she was engaged to a doctor in Waterloo. The engagement lasted about six months, and was then broken off. The deceased spoke to him about her condition on October 2nd, but did not allege that he was the cause of it. He offered to marry her, but she refused. The first he knew of her death was on the Friday morning, when Major Blackburne, her brother-in-law, telephoned the news to him.

Sir Bernard Spilsbury, who conducted a *post-mortem* examination, said that in his opinion death was due to shock consequent upon and following immediately after the use of an instrument; she was pregnant, probably two months.

The deputy coroner (Colonel H. Parker), in his summing up to the jury, said the deceased was perfectly well when she went to Dr. Webster's house, and, according to Sir Bernard Spilsbury, what took place there was criminal. They had to consider whether Dr. Holden or Dr. Webster was responsible, and, having regard to the facts, he did not see how they could separate the one from the other. Further, they must consider the responsibility of any other persons.

The jury returned a verdict as stated.

### A SPECIALIST'S FEES.

MR. E. J. DECK, M.R.C.S., L.R.C.P., of Welbeck Street, London, succeeded before Mr. Justice Roche and a special jury, in the King's Bench Division of the High Court of Justice, on October 27th and 28th, in establishing his claim against Captain A. G. Godwin Smith for the sum of £65, being fees for medical attendance.

The defendant pleaded that he consulted Mr. Deck for swellings on the side and back of his neck, but that the attendances were of no value to him by reason of the negligence of Mr. Deck, who, he alleged, wrongly diagnosed his ailment and directed treatment—ultra-violet rays and extraction of teeth—which injured his health. For such alleged negligence he counter-claimed damages.

The plaintiff, by his reply, denied negligence.

Mr. H. F. Dickens and Mr. J. M. Symmons appeared for the plaintiff. Mr. H. J. Wallington appeared for the defendant.

### The Plaintiff's Case.

Mr. Dickens said Mr. Deck before the war practised in New Zealand, and during the war he served with the New Zealand Army Medical Service. Becoming an authority on the ultra-violet ray treatment, which was coming into favour with medical men for its healing properties, he, after the war, equipped his consulting room in London with the necessary apparatus, and his whole-body ray bath was the first installed in England. Mr. Deck had personally administered the rays 25,000 times. On February 11th, 1925, the defendant was sent to him for consultation as to swellings at the side of the face and neck and back of the neck. He formed the opinion that the swelling of the face was an infection of the glands due to poisoning in the system, and an x-ray examination revealed that the condition of the defendant's teeth and gums was a sufficient cause, and between July 1st and 9th Captain Smith's teeth were extracted by Mr. Byrne, a dental surgeon, in Welbeck Street. Captain Smith's condition improved, and the swelling at the back of the neck decreased. In August he spent a holiday in Cornwall, but on his return in September the swelling at the back of the neck was found to have increased.

Blood tests showed that there was no poisoning, and it became clear that he was suffering from a tumour. The plaintiff advised him to undergo an operation, but Captain Smith was unwilling. Later, Captain Smith wrote that he had consulted Mr. Donald Armour, who had diagnosed the complaint as a tumour. Mr. Armour operated, removed the tumour, and Captain Smith recovered. When, however, the plaintiff demanded his fees, Captain Smith merely replied that if Mr. Deck desired to go into court he should welcome the opportunity of asking him a few questions.

Mr. Deck gave evidence in support of his counsel's opening. He had told Captain Smith he thought the swelling at the back of the neck was due to a tumour, but that in view of the history of varying size there was an element of doubt. Captain Smith was eager to have his treatment because he wanted to avoid an operation. In cross-examination, Mr. Deck said if the rays were applied directly there was no reason why they should provoke growth of the tumour as they did not act on fat, but through the blood stream. He did not think eight months an excessive time for him to take in making a definite diagnosis in this case. Captain Smith never said he would like a second opinion.

Mr. Ferdinand Byrne, dental surgeon, said the radiogram taken of Captain Smith's mouth showed marked absorption of the bones surrounding the teeth; in extracting the teeth he acted on his own, and not on Mr. Deck's opinion. Captain Smith still owed his fees for the dental treatment.

Mr. Eric W. Pedley, dental radiologist, who x-rayed Captain Smith's mouth, agreed that the extraction was necessary.

Sir Alfred Fripp spoke of Mr. Deck as one of the best known specialists in ultra-violet ray treatment, and said he considered the fees charged very reasonable.

Mr. Justice Roche: The moderation of most doctors with regard to fees always surprises me.

Sir Alfred Fripp said the rays had proved themselves valuable in cases where the reduction of inflammatory swelling was desired.

### The Defendant's Case.

Mr. Wallington, for the defendant, said the truth was that, as Mr. Deck had told Sir Alfred Fripp, he regarded the case as a very interesting one, and he was very eager to cure it with the ultra-violet rays, in which he specialized. It was not until September that Mr. Deck suggested that the swelling at the back of the neck was a tumour, and the operation, which would have been simple in February, 1925, was not so simple in the following October.

Captain Smith bore out his counsel's statement.

Mr. Donald Armour, F.R.C.S., who operated for the tumour, in cross-examination, agreed that the diagnosis of the tumour was not necessarily as easy in February as in October.

Mr. Dickens: If a doctor were in doubt, would it be proper to attempt to reduce swelling by ultra-violet ray treatment?—Yes.

Mr. Dickens: And, if the swelling subsided, the doctor would be justified in continuing the treatment?—Yes.

The jury returned a verdict for the plaintiff, and judgement was entered for him on the claim and counter-claim, with High Court costs.

## The Services.

### BELFAST UNIVERSITY SERVICES CLUB.

The eighth annual armistice dinner of the Belfast University Services Club will be held in Thompson's Restaurant, Donegal Place, Belfast, on Thursday, November 11th, at 8 p.m. All past Queensmen who served during the great war in His Majesty's Forces are invited to attend, and those who wish to do so should signify their intentions to the Honorary Secretaries, Services Club, The University, Belfast, before November 10th. The cost of the dinner (exclusive of wines) will be 12s. 6d.

On the morning of November 11th, at the conclusion of the "two minutes' silence," a wreath from the club will be laid at the base of the war memorial in the University, and all past and present Queensmen are invited to be present.

### DEATHS IN THE SERVICES.

SURGEON-GENERAL WILLIAM BUDD SLAUGHTER, Army Medical Service (ret.), died at Colchester on October 22nd, aged 77. He was born at Farningham, Kent, on December 31st, 1848, and was educated at St. Thomas's Hospital; he took the L.S.A. in 1870, and the M.R.C.S. in 1871. He entered the army as assistant surgeon on March 30th, 1872, and attained the rank of colonel after exactly thirty years, became surgeon-general on June 21st, 1905, and retired on December 31st, 1908. He served in the Afghan war of 1878-80 (medal), and in the Tirah campaign on the North-West frontier of India in 1897-98 (medal with clasp).

Colonel Bertal Hopton Scott, C.M.G., Army Medical Staff (ret.), died at Ealing on October 24th, aged 65. He was born at Gringley-on-the-Hill, Notts, and was the son of the Rev. G. H. Scott, vicar of that parish. He was educated at Toronto University, where he graduated M.D. and C.M. in 1883, and at the London Hospital, taking the L.R.C.P. Ed. in 1884, the M.R.C.S. in 1885, and the D.P.H. at Cambridge in 1902. He entered the army as surgeon on February 5th, 1887, became colonel in the long promotion list of March 1st, 1915, and retired on September 10th, 1919. He served in the Chitral campaign of 1895, with the relief force, receiving the frontier medal with a clasp; in the operations in Sierra Leone in 1898-99, the Karene expedition, when he was severely wounded in the chest and had his thigh fractured, and received the medal with clasp; in the recent war of 1914-18 he was thrice mentioned in dispatches (1915, 1916, and 1917) and received the C.M.G.

Lieut.-Colonel William Creyk, R.A.M.C. (ret.), died at Pango on August 19th, aged 87. He was educated at Aberdeen, where he graduated M.B. in 1860, taking the L.R.C.S.Ed. in 1861. He entered the army as assistant surgeon on April 14th, 1863, became surgeon major on April 28th, 1876, and retired on May 16th, 1888. During the old regimental days he served in the 4th Foot, the King's Own Royal Lancaster Regiment, from 1865 to 1871, and in the Royal Artillery in 1871-72. He served in the Afghan war of 1878-80, receiving the medal.

## Universities and Colleges.

### UNIVERSITY OF CAMBRIDGE.

The following have been elected to the Board of the Faculty of Medicine for varying periods: T. S. Hele, M.D., R. D. Adrian, M.D., G. S. Graham-Smith, M.D., F.R.S., and W. L. H. Duckworth, M.D., Sc.D.

At a congregation held on October 29th the following medical degrees were conferred:

M.D.—L. R. Cole.  
M.B., B.Ch.—W. W. McLean, R. H. Motcalfe, A. T. Worthington.  
M.B.—J. H. Hauman.

### UNIVERSITY OF LONDON.

#### THE FACULTY OF MEDICINE.

SIR CUTHBERT S. WALLACE, K.C.M.G., C.B., M.B., F.R.C.S., of St. Thomas's Medical School, has been elected Dean of the Faculty of Medicine for the period 1926-28.

#### UNIVERSITY COLLEGE.

The first of a course of four lectures on Insulin was given by Dr. C. H. Best at University College, Gower Street, W.C.1, on Wednesday last. The lectures, which are addressed to students and others interested in the subject, will be continued on succeeding Wednesdays in November at 5 p.m.

### UNIVERSITY OF EDINBURGH.

#### ADDRESS BY THE PRINCIPAL ON THE WORK OF THE YEAR.

AFTER the Principal's address on October 23rd, when 134 degrees were conferred, Sir Alfred Ewing, gave an address on some important developments in the University during the past year.

He referred to the rectorial address delivered by the Prime Minister in his last year of office as Lord Rector, at which the Earl of Balfour had presided, and expressed his gratification that, as a result of the students' organization, these distinguished visitors had received a hearing worthy of the great occasion. Another example of student leadership had been afforded at the time of the general strike when the students voluntarily formed themselves into a Students' Emergency Council, whose activities found expression in many useful deeds and had been of real service to the community; the action then taken, and the manner of it, had brought the student body into a higher level of public esteem than had perhaps ever occupied before.

After an allusion to the celebration in June, 1926, of the bicentenary of the foundation of the Medical Faculty, the Principal went on to instance, among the important developments of different departments, the provision of the laboratory in connexion with the chair of surgery, which had been opened at the bicentenary celebration. This had been carried out with the assistance of the Rockefeller Foundation, which was providing also material assistance towards the erection of a clinical laboratory at present being built in the infirmary grounds. A new radiology department had been opened by the managers of the Royal Infirmary in that institution, which he believed had no rival anywhere, and in connexion with this the University had appointed a lecturer in radiology. Recent gifts had made possible the development of a department of animal breeding, and it was hoped that the University might soon be in a similar position with regard to the zoology department, for which a site had now been definitely selected. Minto House in Chambers Street had recently been acquired by the University to provide accommodation on the department of English and modern languages and so relieve the congestion in the Old Quadrangle.

An important aspect of university life was the number of matriculated students. There had been great congestion in all the universities of the country after the war, and in Edinburgh this had reached its height in the session 1920-21, when there were nearly 5,000 matriculated students. A gradual fall, amounting to between 200 and 250 a year, had thereafter taken place, until the number was approximately 4,000, about which it now appeared to remain steady. Last year the total number had been 3,953. There were indications, he thought, that the numbers were beginning to rise again. It was too early in the session to speak with confidence regarding the coming year, but the entrance of first year students to date considerably exceeded the entrance of first-year students at the same date last year. There had been a very remarkable and sustained rise in the Faculty of Arts, which was now half as large again in numbers as it was in the pre-war years. Medicine and science had both experienced a rush after the war and then something of a slump, but even now science had one and a half times as many students as in pre-war years. An interesting feature in the statistics was the largely increased number of women who entered. Last year, out of 3,953 students, 1,191 had been women, and in the Faculty of Arts more than half of the

whole number were women. In the present year the number of students who had already matriculated showed a proportion of one woman to two men.

### UNIVERSITY OF DUBLIN.

#### SCHOOL OF PHYSIC, TRINITY COLLEGE.

The following candidates have been approved at the examination indicated:

FINAL EXAMINATION.—Part I (*Materia Medica and Therapeutics*; *Medical Jurisprudence and Hygiene*; *Physiology*);  
\*G. C. Dockeray, S. Boggs, R. H. Blair  
H. E. Knott, I. W. Pigott, In Com.  
Gamble, J. Horwich, E. K. Malone, C. E. G. Nunns.

\* Passed on high marks.

### NATIONAL UNIVERSITY OF IRELAND.

At the yearly meeting of the Senate, held on October 29th, the Senate had under consideration the reports of the examiners upon the results of the autumn examinations, and awarded passes, honours, etc., in connexion therewith.

The following awards were made in connexion with the Medical Faculty:—Dr. Henry Hutchinson Stewart Medical Scholarships: (1) Anatomy and (2) Physiology, J. F. O'Dea; Dr. and Mrs. W. A. Broune Gold Medal and Prize: Mary B. O'Mahony (gold medal), Lily M. McDermott (prize).

The Senate decided that a special final medical examination should be held in January, 1927, in University Colleges, Dublin, Cork, and Galway, provided that not fewer than seventy-five candidates enter and pay the special entry fee of £5 on or before November 18th.

The Senate also decided that the Dr. Henry Hutchinson Stewart Scholarships in Medicine shall be offered for competition in 1927.

### ROYAL COLLEGE OF PHYSICIANS OF LONDON.

An ordinary quarterly comitia of the Royal College of Physicians of London was held on October 28th, at 5 p.m., when the President, Sir John Rose Bradford, was in the chair.

#### Membership.

After the minutes of the Censors' Board had been read, the following candidates were admitted as Members:

K. B. Aikman, M.D.Camb., R. D. Alexander, M.B.Camb., H. Cohen, M.D.Liverp., W. R. P. Collis, M.B.Camb., H. A. Colwell, M.B.Lond., Surg.-Com. J. G. Danson, H. N. M.D. Verd., I. G. Davies, M.B.Lond., Dinsbaw H. Dudha, M.D.Bombay, V. Feldman, M.B.Lond., G. Fletcher, M.D.Glasg., C. S. Hallpike, M.B.Lond., G. E. R. Hamilton, M.B.Lond., F. M. D. A. Har, M.B.Camb., B. D. Hawes, L. R. C. P., R. Jerom, M.B.Syd., E. H. Kett, M.D.Lond., J. R. Landreth, M.B.New Zealand, O. C. Moller, M.B.New Zealand, A. T. Nankivell, M.D.Lond., C. E. Newman, M.B.Lond., A. Pool, M.B. Liverp., A. D. Porter, M.B.Camb., E. A. B. Pritchard, M.B.Camb., E. Scott, M.B.Liverp., S. B. Simaika, L.R.O.P., Sir E. S. Taylor, Bt., O.R.E., M.D.Camb., P. B. Wilkinson, M.B.Lond., L. J. Witts, M.D.Manch.

#### Licences.

Licences to practise were granted to the following 185 candidates who had passed the Final Examination in Medicine, Surgery, and Midwifery of the Examining Board in England:

Y. Abdel-Messiah, A. Ali, G. E. Ailing, J. H. Anderson, G. F. Andrews, M. C. Andrews, H. W. Applin, J. M. Ashion, E. Awroubi, L. G. Backhurst, "Grace Batten," Rosie B. Becker, M. Behr, "Florence K. Bibby, G. Biedman, G. W. Black, E. J. O. Bockett, E. S. Bolton," Susanna M. Bornman, J. W. Bottoms, H. W. Bowen, E. Bowen-Jones, H. Bown, F. W. Bradley, J. G. Braddon-Bravo, W. A. Briggs, M. Bryer, R. H. Burns, "I. Caley, C. J. N. Cameron, S. Carnofsky, J. C. D. Carothers, W. H. Carr, J. R. B. Chatterton, J. A. Chalmers, S. I. A. Clarke, P. F. Cluver, A. Cohen, W. K. Coombes, D. H. Couch, H. T. Cox, E. S. Curless, R. P. P. Davies, "Winifred M. De Kok, A. C. De Sousa, A. A. Digges in Douche, T. A. J. M. Dodd, J. Dywien, "Phyllis M. Edgar, H. M. Elliott, E. A. E. Emmon, H. K. Evans, "Leonora S. Evans, S. H. Evans, W. G. Evans, A. W. Fawcett, "Dorothy D. Forster, A. E. Fraser-Smith, E. G. Frower, A. H. Gale, "Margaret E. J. Gashion, J. B. George, "Dorothy Gibbs, R. M. Gilchrist, H. K. Goadby, "Myrtle S. M. Goldrich, J. A. Gornall, J. Gough, R. A. Graff, E. C. Grant, T. L. Griffiths, H. L. Gulati, G. S. Hall, A. C. de H. Helme, G. F. Henderson, G. R. N. Henry, V. V. H. Hoaki, O. Hooper, H. O. Hopkins, F. S. Hubberty, T. C. Hunt, C. B. Huss, A. B. Hyman, R. Illingworth, A. J. Johnson, E. C. Johnson, "Louise A. Johnson, C. W. Jones, W. T. Jones, F. E. Kingston, F. Knolly, L. C. Lancaster, P. R. Lamsdell, C. J. Laviers, H. W. Lewis-Phillips, D. G. Lloyd, "Flora W. Lloyd, G. E. Macdonald, J. R. Macdonald, J. C. MacFadden, W. H. S. McGregor, W. McLaren, H. E. McLaughlin, W. N. Macleay, D. H. Madge, P. C. Mallam, S. M. Mallick, C. Mani, "In M. N. Menon, R. J. Milbank, "Barbara itchell, E. R. W. Mons-Gla, R. H. W. Mori, "Morris, E. F. Morton, B. E. T. Mosse, B., "E. F. D. Owen, G. E. Parker, N. D. Patel, L. L. P. Paterson, R. H. Pearce, "Janet R. Phillips, R. A. Phillips, C. B. Picken, E. A. Pim, "Winifred A. L. "Lesley M. C. Probyn, "Hilda M. Richards, A. H. "P. Rose, A. W. L. Row, G. P. Roxburgh, J. A. Rushworth, B. F. Russell, N. A. Sait, F. G. A. Shabeeb, G. C. Shepherd, H. L. Shimmim, D. P. Simson, J. W. Simpson, B. A. Smith, R. Smith, E. R. Smithard, W. R. C. Spicer, "K. Stephen, C. E. R. Stephenson, O. L. Stote, R. Stuppel, F. J. Swinton-Eber, H. Syed, W. K. Targett, J. E. Teale, J. G. T. Thomas, A. R. Thompson, O. L. Truscott, "I. Tuckett, F. B. Turner, "Aimée A. L. Vallant, L. S. P. Wakeley, A. C. R. Walton, "Kathleen M. Ward, N. Wessell, R. Watson, T. O. S. Webb, W. N. Weink, "Beatrice A. Winslow, L. S. Williams, A. A. Wilson, A. G. Wilson, C. S. Wise, A. H. Wortman.

\* Under the Medical Act, 1876.

*Standing Counsel.*

Mr. F. H. Maugham, K.C., was appointed senior standing counsel on the nomination of the President, vice Mr. A. C. Chauson, K.C., appointed a Judge in the High Court of Justice.

*The Richard Bright Celebration.*

It was resolved that a conversazione should be held at the College in 1927 in honour of the centenary of the publication of Richard Bright's book, the date to be fixed so as to coincide with the celebration at Guy's Hospital.

*Final Conjoint Examination.*

On the motion of Dr. Fairbairn, it was resolved that the Committee of Management be asked to report to the College on the efficiency of the examination in midwifery and diseases peculiar to women in the Final Examination of the Conjoint Board.

*Committee of Management.*

Dr. H. L. Tidy was elected a member of the Committee of Management in place of Sir William Hale-White, who has resigned after eight and a half years of service. Dr. Raymond Crawford, who retired in rotation, was re-elected.

*Home Office.*

Two communications were received from the Home Office, the one inviting the College to lay its views before the Committee on the Poisons and Pharmacy Acts, and the other inviting the College to nominate a representative to serve on the tribunal for England and Wales under the Dangerous Drugs Act. Sir William Hale-White was nominated, with Dr. J. Fawcett as his substitute to act if necessary.

*Dr. Nathaniel Johnstone.*

Dr. A. J. Hall of Sheffield was thanked for the gift of a photograph of Dr. Nathaniel Johnstone, a former Fellow of the College, together with some biographical notes.

*Places of Study.*

In 1918 certain places in Austria and Germany were removed from the list of recognized places of were admissible to the final examination received for their restoration. The has now received from the German and Austrian embassies assurances that British doctors are admissible to the Staats examen in these countries by the recognition of their studies and examinations in Great Britain. The following places were recognized:

*Austria:* Graz, Innsbruck, Vienna. *Czecho-Slovakia:* Prague. *Germany:*

*Science Abstracts.*

A report was received from Lord Dawson on his conference with the Medical Research Council in regard to the continuation of the publication of the *Science Abstracts*.

*Donations to the Library: Portrait of Sir R. Douglas Powell.*

Books and other donations presented to the library during the past quarter were received and thanks returned to the donors. The replica of the portrait of the late Sir Richard Douglas Powell, Bt., a former President of the College, given by the Dowager Lady Powell and by Colonel Sir Douglas Powell, was on view.

## Medical News.

At the annual meeting of Fellows and Members of the Royal College of Surgeons of England, to be held on Thursday, November 18th, at 3 p.m., a resolution will be moved by Dr. H. Wansey Bayly and seconded by Dr. Redmond Roche, on behalf of the Society of Members of the College, affirming again the desirability of admitting Members to direct representation upon the Council, and requesting the Council to take a postal vote of Fellows and Members on this general principle. The new president of the society is Dr. Ernest E. Ware, and the honorary secretary is Dr. S. C. Lawrence, 106, Richmond Park Road, Bournemouth. In a letter accompanying the notification Dr. Lawrence draws attention to the fact that the Council of the College has not yet altered By-law xxvi forbidding women to attend or vote at meetings, although the new Supplementary Charter, which grants women members the same privileges as men, was signed by His Majesty last July.

On November 11th, at 5 p.m., at the house of the Medical Society, 11, Chandos Street, W.1, Mr. Arthur E. Giles will give the sixth lecture in the series arranged by the Fellowship of Medicine on emergencies; he will speak on emergencies in gynaecological practice. On the same date, at 1 p.m., Mr. Maurice Whiting will give a demonstration in clinical ophthalmology at the Royal London Ophthalmic Hospital. Mr. L. C. Rivett will give a clinical demonstration at the Chelsea Hospital on November 12th, at 2 p.m. The lecture and demonstrations are open to medical practitioners without fee. The Royal Waterloo Hospital will hold a course in medicine, surgery, and gynaecology from November 15th to December 4th, with special reference to endocrine deficiency, diseases of the blood, thyroid gland,

respiratory system, stomach and intestines, and modern methods of laboratory diagnosis. From November 15th for one month there will be a clinical course in dermatology at the St. John's Hospital, including two lectures a week, and also a series of practical demonstrations in pathology if desired. A week's comprehensive course in diseases of the rectum will start at St. Mark's Hospital on November 22nd, and will include the use of the sigmoidoscope. For four weeks from November 22nd there will be a course at the West End Hospital for Nervous Diseases, 73, Welbeck Street, W., commencing at 5 p.m. each day. A course for general practitioners will be provided by the London Temperance Hospital from November 29th to December 11th, and courses in obstetrics are available at Queen Charlotte's Hospital and the City of London Maternity Hospital; practical courses in anaesthetics can also be arranged. Copies of all syllabuses and of the general course programme may be obtained from the Secretary of the Fellowship, 1, Wimpole Street, W.1.

THE Post-Graduate Hostel meeting to be held at the Imperial Hotel, Russell Square, W.C.1, on Tuesday, November 9th, at 9 p.m., will be addressed by Dr. S. Wright on the output of the heart in health and disease. On Thursday, November 11th, at 9 p.m., Mr. H. A. Harris, F.R.C.S., will discuss epiphyses. All medical practitioners are welcome. Dinner will be served at 8 p.m. (price 5s.) and coffee and biscuits at 10 p.m. (price 6d.).

THE National Council for Mental Hygiene has arranged a public meeting at the house of the Royal Society of Medicine on November 17th, at 4.45 p.m., when the chairman will be Lord Southborough, and an address will be given by the Right Hon. H. P. Macmillan, K.C., chairman of the Royal Commission on Lunacy and Mental Disorder, 1924-26. The third report of the National Council contains references to the report of the Royal Commission and to the inquiry into the value of psycho-analysis as a method of treatment. The latter subject was referred to a subcommittee for report, but it is announced that no decision has yet been reached. Three subcommittees of the council during the year under review dealt with the prevention and early treatment of mental disorder; the care, after-care, and treatment of the insane; and mental deficiency and crime. The evidence submitted by Dr. W. A. Potts to the Home Office Committee on the treatment of young offenders is published as an appendix to the report.

PROFESSOR W. W. C. TOPLEY will deliver the Harben Lectures at the Royal Institute of Public Health in the lecture theatre of the Institute (37, Russell Square, W.C.) on November 15th, 18th, and 22nd, at 4 p.m. on each day. His subject will be quantitative experiments in the study of infection and resistance; no tickets of admission are required.

A SERIES of three lectures on the history of medicine will be given at the University of Durham College of Medicine, Newcastle-upon-Tyne, during the academic year 1926-27, by Dr. Charles Singer, of University College, London. The first lecture will be delivered on Friday, November 19th, at 4.45 p.m. All medical practitioners in the neighbourhood are invited to attend.

A FURTHER extraordinary general meeting of the Medical Sickness, Annuity and Life Assurance Society was held at the offices of the company, Lincoln House, 300, High Holborn, W.C.1, on November 1st. The resolution approving the new Articles of Association of the society adopted at the meeting on October 11th (BRITISH MEDICAL JOURNAL, October 16th, p. 693) was unanimously confirmed.

AT a meeting of the Hunterian Society of London in the Cutlers' Hall, Warwick Lane, E.C., on Monday, November 15th, at 8.45 p.m., a discussion will be held on medicine and the press. The speakers will include Sir Humphry Rolleston, Bt., Dr. Graham Little, M.P., Dr. Leonard Williams, and prominent persons connected with the newspaper press. Fellows may bring non-medical guests.

The annual dinner of past and present students of the Royal Dental Hospital of London will be held at the Trocadero Restaurant on Saturday, November 20th, at 7 o'clock, with Mr. W. H. Dolamore in the chair. The staff will hold its annual clinical "At Home" at the hospital, Leicester Square, on the afternoon of the same day at 2 o'clock. Cases of special clinical interest which have come under observation and treatment during the past year will be shown and demonstrations given. The Medical Committee extends an invitation to any medical practitioners who may like to attend.

THE first of the Malcolm Morris memorial lectures will be given in the Barnes Hall of the Royal Society of Medicine, 1, Wimpole Street, W.1, on November 15th, at 5.15 p.m., by Professor H. J. Fleure, who will speak on racial characters of the human skin and racial types in relation to health problems. The fund for the lectures, which have to deal with dermatology and public health in alternate years, has been transferred by the Memorial Committee to the Chadwick Trustees for administration.

At the meeting of the Pharmacological Society of Great Britain at 17, Bloomsbury Square, W.C., on Tuesday, November 9th, at 8 p.m., a paper on "Some methods of biological assay" will be read by Dr. J. H. Burn, director of the society's pharmacological laboratories. Medical friends of members and student-associates will be welcomed.

The annual dinner of the West Riding Association of Graduates of the Edinburgh University will be held at the Midland Hotel, Bradford, on Wednesday, November 17th, at 7.15 p.m. Professor Kemp Smith, dean of the faculty of arts, will be the guest of the evening. Further information can be obtained from Dr. Donald Watson, 33, Manor Row, Bradford.

The annual dinner of the Society of Medical Officers of Health will be held at the Piccadilly Hotel, on Thursday, November 18th, at 7.30 p.m. Ladies are invited, and members, or candidates nominated for election, are asked to give early notice to the Executive Secretary of their intention to be present, with the names of their guests. A payment of 12s. 6d. for each ticket should be made with applications sent before November 15th; after that date the cost of tickets will be 15s. each.

The Continental Medical Graduates' Association (formerly the Brussels University Medical Graduates' Association) held its annual dinner at the Langham Hotel, on October 28th, with the president, Dr. H. Fielden Briggs, in the chair. In proposing prosperity to the association Sir Henry Jackson, M.P., M.B., coupled the toast with the name of the president, who, in his reply, gave an outline of its history and indicated the objects to be attained in the future. These, Dr. Fielden Briggs explained, were scientific and political; under the former heading would come the winter meetings, at which eminent men would be asked to read papers, and congresses in the summer to be held at various Continental cities; with regard to the latter, they would press for reciprocity of medical practice between this country and the European nations. Although millions of English tourists and residents were on the Continent, they were unable to be attended by their own British medical man because they were prohibited from practising in those countries. Mr. Hugh Edwards, M.P., agreed with the president's remarks, and instanced his own experience on the Continent, when, being ill, he was unable to avail himself of the services of his own medical adviser because it was useless to send to England for him as he would not legally be allowed to attend him. Dr. Leonard Williams, in a humorous speech, proposed the toast of "The Ladies," and Dr. Justina Wilson, in replying, contrasted the reception given to post-graduates on the Continent and that given in this country. Sir Thomas Corey-Evans proposed "Kindred Societies," and Mr. Mortimer Woolf, president of the Hunterian Society, and Dr. Ernest Young, president of the Chelsea Clinical Society, responded. The president's health was proposed by Dr. Campbell McClure, and Dr. Fielden Briggs, in replying, paid tribute to the honorary secretary, Dr. A. D. Woolf, for his arduous labours on behalf of the association.

At the first general meeting of the League of National Life, held in the Caxton Hall, London, on October 29th, with Lord Fitzalan in the chair, the president, Dr. F. J. McCann, said that it was felt that contraception was becoming a great national problem, and that accordingly the league had been formed to influence public opinion along what they believed to be the correct lines, and to foster the perpetuation of family life. After a large experience Dr. McCann affirmed that the practice of contraception should be condemned because it was physically harmful to the female. The more complete the interference with the physiological character of the act the greater the harmfulness. The continued use of contraceptives had an important relationship to some of the major and many of the minor ailments whose cause was regarded as obscure. Dr. Halliday Sutherland (honorary secretary) said that the immediate policy of the league was to have the various fallacies of birth prevention exposed by experts—ethical, medical, statistical, and sociological. Dr. Letitia Fairfield said that perhaps the chief difficulty in propaganda work would be the fact that birth control was advocated as a panacea for every conceivable social evil, and those who undertook to oppose it were made to appear as reactionary or inhuman supporters of these evils.

Dr. F. J. BAILEY, well known to many members of the British Medical Association as a representative and committeeman, has been elected for the fourth time President of the Southport Society of Natural Science. At the opening meeting of the thirty-seventh session of the society on October 21st, at which the Mayor and Mayoress of Southport attended, Dr. Bailey gave his presidential address on "Some pioneers and prophets of science." In this he spoke of the great development which took place during the war in scientific matters, which compensated to some extent for the losses suffered. He traced the progress in art and science

and medicine from the days of the Egyptians, Greeks, and Romans, through the Middle Ages and down to the present time. His conclusion was that the development during the last fifty years in science and its application to life in commerce and industry has been greater than in all the preceding ages.

QUESTIONS of importance concerning the future of British spas were discussed at the autumn meeting of the British Spa Federation, held recently in London, and attended by representatives of all the leading spas in Britain. The organization is being developed for dealing with insured persons, so that when spa treatment for rheumatic diseases is made an additional benefit under the National Health Insurance scheme the patients may obtain the best results without any confusion or interference with the ordinary visitors to the spas. Other subjects discussed were the extension and co-ordination of scientific research into the chemical and physical properties of the mineral waters of Great Britain, and the relation of the spas with the "Come to Britain" Movement and other efforts towards meeting foreign competition.

AN x-ray apparatus and a new orthopaedic pavilion have been installed at the Warrington Infirmary. The x-ray apparatus, which cost £400, was presented by the employees of Messrs. Pearson and Knowles as a memorial to the late Mr. Gordon H. Fraser, managing director. The orthopaedic pavilion, which cost £1,800, is fully equipped with gymnastic apparatus and appliances for the administration of artificial sunlight treatment. It was opened by Mr. H. Wade Deacon, vice-president of the council of the British Hospitals Association and chairman of the board of management of the Liverpool Royal Infirmary.

DR. R. M. LITTLE, on his retirement from the post of medical officer to the Southport Post Office, has been presented by the staff with a travelling clock.

DURING the week ending September 25th 6 fatal cases of plague, 79 cases of cholera with 25 deaths, and 27 cases of small-pox with 10 deaths were reported by the Far East Bureau at Singapore, and during the week ending October 2nd 47 cases of cholera with 10 deaths, and 21 cases of small-pox with 11 deaths were reported.

PROFESSOR HENSCHEN of St. Gall has been appointed successor to the late Professor Holtz in the chair of clinical surgery at Basle, and Professor Ziemcke of Kiel has been appointed professor of medical jurisprudence at Breslau.

## Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to **The EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.**

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the **BRITISH MEDICAL JOURNAL** alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the **BRITISH MEDICAL JOURNAL** must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the **JOURNAL**, should be addressed to the Financial Secretary and Business Manager.

The **TELEPHONE NUMBERS** of the British Medical Association and the **BRITISH MEDICAL JOURNAL** are **MUSEUM 9861, 9862, 9863, and 9864** (internal exchange, four lines).

The **TELEGRAPHIC ADDRESSES** are:

**EDITOR** of the **BRITISH MEDICAL JOURNAL**, *Aitiology Westcent, London.*

**FINANCIAL SECRETARY AND BUSINESS MANAGER** (Advertisements, etc.), *Articulate Westcent, London.*

**MEDICAL SECRETARY**, *Mediscera Westcent, London.*

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Bacillus, Dublin*; telephone: 4737 Dublin), and of the Scottish Office, 6, Drumsheugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone: 4361 Central).

## QUERIES AND ANSWERS.

### CHILBLAINS.

"C. P. J." asks for suggestions in the treatment and prevention of chilblains in a patient who suffers every year with the advent of frosty weather, both on hands and feet. She takes plenty of exercise throughout the year, and also takes cod-liver oil and extract of malt, together with calcium lactate gr. xv t.i.d., but in spite of this the chilblains recur and persist. Local treatment consists in the application of counter irritants—iodine,

methyl salicylate ointment, etc. Our correspondent wonders if an injection of horse serum would be of benefit in increasing the coagulability of the blood.

#### INCOME TAX.

##### Schedule E: Expenses.

"C. R. G." has claimed to deduct from his salary expenses incurred for medical periodicals and upkeep of medical library. The inspector of taxes has refused the claim, referring him to the decision of Rowlatt, J., in the case of Simpson v. Tate.

\* \* The refusal is in accordance with the law, as judicially laid down; "C. R. G." has no prospect of appealing successfully unless he can show that the purchase of the medical literature (or membership of the societies distributing it to him) was a condition of his appointment to the office he holds.

##### Cash Basis.

"R. M. W." is being pressed by the inspector of taxes to render his firm's returns on the basis of actual bookings; past returns have been prepared by chartered accountants on the basis of actual receipts.

\* \* It is officially agreed, we believe, that the basis of actual bookings is incorrect and also unfair to the practitioner unless it is modified by the deduction—authorized by law—of a carefully made estimate of anticipated loss by reason of bad debts. That estimate it is almost impossible to prepare in such circumstances as "R. M. W.'s," except on the basis that the percentage lost in the past is likely to be the ratio of loss in the future. If the amount of debts outstanding does not differ materially from one year to another, the result of taking such an estimate will be the same as of preparing the returns on a cash basis. This is the reason why it is a well recognized custom on the part of inspectors of taxes to accept the cash basis in the case of medical practices. If our correspondent's gross bookings have been increasing, then the "cash" returns are lagging behind the true earnings of the practice, and he has no answer (theoretically, at least) to the inspector's contention, but if bookings are not increasing, we think that an application to the Board of Inland Revenue, Somerset House, would probably receive sympathetic consideration.

"P., T., and R."—A, B, and C were in partnership until June 30th, 1926, when A left the firm, undertaking not to act as a general practitioner, but carried on as a surgeon and consultant. How should the assessment for 1926-27 be dealt with, and can A and/or B and C claim "specific cause"?

\* \* The old ratio of division will, of course, apply for the first quarter of 1926-27. For the remaining three quarters the average should be reconstructed, separating A's specialized work from the general practice now carried on by B and C and dividing the remainder of the assessment accordingly. The question of "specific cause" is, in the circumstances, somewhat intricate, and, as it is at present a hypothetical one, we suggest that it be referred again when the result of the next accounts—that is, for nine months to March 31st, 1927—is available.

#### ESTATE DUTY.

"M.D."—Dr. X. died in 1918, leaving a small estate. His will provided *inter alia* for payment of an annuity of £80 to a dependant. The annuitant has now died, and the Inland Revenue claim payment of a further estate duty upon the sum which had been invested to provide for payment of the annuity.

\* \* The facts appear to be within the rule laid down in *Attorney-General v. Watson and others* [1917], 2 K.B., 427, in which it was held that the cesser of an annuity gives rise to a claim for duty. In dealing with the statutory provisions (Finance Act, 1894, Sec. 2 (1) (b), Lush, J., said: "The object of the section is to make estate duty payable whenever there has been a succession, in fact, or that which is equivalent to a succession—whenever there has been a cesser of an annuity by reason of the death of the annuitant, which cesser causes a benefit to accrue to that property."

#### LETTERS, NOTES, ETC.

##### CHOLECYSTOGRAPHY.

Mr. G. P. B. HUDDY, M.S., F.R.C.S. (Dudley Road Hospital, Birmingham), writes: The fatality following the injection of sodium tetraiodophosphthalein, referred to in your issue of September 18th (p. 542) and again on October 2nd (p. 620), occurred in a patient under my care and was brought to the notice of the medical profession in the *Lancet* of September 4th (p. 509).

The patient was a woman, aged 46, and her weight was 11 st. 12 lb. The dose given was 51 grams in 40 c.cm. of triple distilled water, this being the maximum dose used by Professor D. P. D. WILKIE (*BRITISH MEDICAL JOURNAL*, 1925, ii, p. 1046). I gave the injection myself, and it was carried out very slowly, during a period of over twenty minutes. During the injection the patient complained of abdominal pain, which was followed by vomiting and headache. Immediately after the completion

of the injection the pain became so severe that she rolled about and screamed. The body became rigid, there was frothing at the mouth, and then loss of consciousness. The pulse and respiration became more and more feeble, the pupils dilated, and death ensued in spite of all efforts at resuscitation.

The makers of the preparation were immediately informed and samples were tested, but no alteration in the compound could be detected. I should like to point out that, contrary to my previous practice, the solution had been made up the day before use. Another patient injected immediately preceding and under similar circumstances had a more severe reaction than is usual.

The amount of drug used by different workers has varied, and, in view of the above experience, I feel that some patients are particularly susceptible, and that the amount given in this case is too high for general use. This would seem to be confirmed by Mr. Stanford Cade, who, using a smaller maximum dose of 4½ grams, observed in two consecutive cases a very similar train of symptoms to that described above. In describing the cases he states "... the pulse at the wrist could not be felt for half to three-quarters of an hour" (*Lancet*, July 3rd, p. 5). The injection of the solution in two portions, with a short interval between, is a safeguard, for the symptoms develop rapidly, and by adopting this procedure the second portion could be omitted if advisable.

The value of intravenous injection of sodium tetraiodophosphthalein is to be estimated by the increased percentage of correct diagnoses so obtained over that obtained by ordinary clinical and other means of investigation, including oral administration of the drug.

##### AN ACID DENTIFRICE.

DR. W. J. HENSON (London, W.) writes: Six years ago (*JOURNAL*, 1921, vol. i, p. 408) you published a letter from me under the above heading. I have had before me correspondence from doctors and dentists in all parts of the world, and up to the present not one has controverted my assertion that alkali and soap, forming the basis of the major part of the tooth pastes in modern use, depress the flow of alkaline saliva, which is Nature's preventive of pyorrhoæa and dental decay. On the occasion to which I refer I gave the ingredients of a fruit acid tooth paste formula which I had used in my practice for a number of years, and now, after this lapse of time, I am in a position to confirm my former statement that I have never seen a recurrence of pyorrhoæa or decay in any case in which it has been properly used.

##### PLUMBO-SOLVENT WATERS.

"HYDRAULIC ENGINEER" writes: The method advocated by Dr. T. D. Harries (October 23rd, p. 764) for safeguarding the public against dangers incurred by the use of lead pipes for the conveyance of soft water is as effective as it is simple, and can be applied with equal advantage to the water supplies of towns, villages, schools, and country houses. It is now for the authorities to broadcast the information given by Dr. Harries, which can justly be proclaimed as a most valuable contribution in the cause of public health.

##### GARLIC IN PNEUMONIA.

DR. C. J. HILL AITKEN (Kilnhurst, Yorks), writing with reference to a Memorandum by Dr. F. W. Crossman (*JOURNAL*, 1924, vol. i, p. 519), in which it was stated that the use in pneumonia of a spirituous tincture of the garlic bulb brought about a rapid cure, relates that in two cases under his care in which it was proposed to employ this remedy the crisis occurred on the fifth and sixth days of the illness respectively, and before the drug was obtained. In another case the crisis came after a dose of castor oil, and in yet another after a change in the medicine. Subsequently to reading the article on garlic, he noticed a statement made at a medical meeting that pneumonia had changed its type and was tending to abort much sooner than the eighth day. In twelve months he had a series of thirty-six cases of pneumonia in which the treatment was on ordinary lines, without one death. He thinks that this result justifies the continuance of the treatment of pneumonia in the usual way, and that the good results ascribed to garlic may be of the nature of *post hoc ergo propter hoc*.

##### CORRIGENDA.

THE writer of the review of the current issue of *Brain* in last week's *JOURNAL* (p. 793) calls attention to a sentence in which the insertion of the word "and" commences in the ninth line the review, and should read as follows: "The drum is rotated in a clockwise direction viewed from above, nystagmus develops in an individual watching the drum," etc.

IN the report of the discussion on "Surgery and the Workmen's Compensation Act" at the Royal Society of Medicine (*JOURNAL*, October 30th, p. 788), by a reporter's slip the few remarks stated to have been made by Mr. Maynard Smith should have been attributed to Mr. Maynard Heath. Our sincere apologies are due to both gentlemen.

##### VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 47, 48, 49, 52, and 53 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 50 and 51.

A short summary of vacant posts notified in the advertisement column appears in the *Supplement* at page 207.

## THE CANCER PROBLEM.

A SUMMARY OF THE LLOYD ROBERTS MEMORIAL LECTURE.\*

BY

W. E. GYE, M.D.,

PATHOLOGIST, MEDICAL RESEARCH COUNCIL'S FARM LABORATORIES,  
MILL HILL.

I DESIRE to express my thanks for the honour of being asked to deliver this, the fourth of the lectures established to perpetuate the memory of Lloyd Roberts. The subject which I have chosen for the lecture is not entirely within the special field of medicine in which Lloyd Roberts was an acknowledged master, but my hope is that what I have to say will be of sufficient interest to make the lecture worthy of the occasion.

I shall begin by indicating at once my general viewpoint on the subject of cancer, and I cannot do better than quote a few words from the introductory note of the first scientific report of the Imperial Cancer Research Fund (1904):

"The combined histological and clinical observations of the last fifty years have established the malignant new growths as a natural group related to each other by fundamental common attributes. The explanation of those common fundamental characters is bound up with the mode of origin of malignant new growths, and is the problem awaiting solution, to be followed by the specific explanation of individual variations as its natural corollary."

I do not know how far this would meet with general approval. There are some very distinguished pathologists who take the view that there is no common cause of the fundamental characters of new growths; to such the search for a cause of the disease is an irrational pursuit. This view I regard as simply obscurantist, and so, perforce, I leave it to time and the progress of knowledge to decide the issue.

My task is to tell briefly the essential story of the attempts which have been made to solve the problem set out in the quotation above. Naturally I shall advocate my own views of the solution of the problem, but I am more anxious to show—and if I fail the fault lies with me and not with the facts—that at least the problem has been defined and brought to a practical stage by the immense efforts of experimental pathologists during the last twenty-five years.

The earliest record of cancer experiments goes back to 1775, when Peyrilhe attempted to transfer a human breast cancer to a dog. The experiment was a failure. It has been repeated, with variations, over and over again by numerous observers—by Dupuytren, by Langenbeck (1840), Lebert and Follin, Duplay and Cazin, etc.—and invariably without success. Roux and Metchnikoff, and also Jobling, have attempted to transfer human tumours to anthropoid apes, and failed. All this early work has shown the impossibility of transferring human tumours to the lower animals.

In 1889 Hanau described the first successful transplantation of a carcinoma within the same species. The tumour was of a rat, and in structure was a squamous-cell carcinoma. It was transplanted into two other rats and formed small nodules in both. Pfeiffer (1890) was successful in transferring a melanotic carcinoma of a mouse to other mice. Von Eiselsberg (1890) successfully transplanted a spindle-cell sarcoma of a rat to another rat. Morau (1891) was the first, by the method of transplantation, to cultivate a tumour. He was able to maintain a carcinoma of a mouse for seventeen generations over a period of three years by the inoculation of fragments of the tumour into other mice. Firket (1882) and Velich (1898) were successful in transplanting a spindle-cell sarcoma and a subperiosteal sarcoma of the rat respectively.

These observations attracted but little attention, and it was not until Jensen, Loeb, and Borrel had turned their attention to them that the significance of such work began to be appreciated. The present era of experimental cancer research may be said to date from the publication of Jensen's paper in 1902. His work, which was carried out with a carcinoma of a mouse, confirmed the observations of the previous experimenters already mentioned, in showing

that a malignant tumour can be transmitted indefinitely within the species in which the tumour arises. Further, Jensen was unable to find micro-organisms in the transplanted tumours, and described experiments in which was tested the resistance of the cancer cell to different agents. During the same period Loeb studied a cystic sarcoma of the thyroid of the rat and obtained results essentially similar to those obtained by Jensen. Borrel, working with a mouse carcinoma, added further confirmation.

It will have been observed that the animals used by the experimenters mentioned were rats and mice, and the question now arose as to the occurrence of true new growths in other species. In the first scientific report of the Imperial Cancer Research Fund a list is given of the animal tumours examined in the laboratories of the Fund during the year 1903. Tumours of the most varied histological kinds, sarcomata and carcinomata, of the following animals are mentioned: cow, dog, horse, sheep, pig, mouse, cat, hen, Indian parakeet, giant salamander, cod, gurnard, and trout. Since that time observations of pathologists throughout the world have established definitely the fact that new growths occur commonly in all the lower animals, both domesticated and wild. Cancer is not, therefore, a purely human disease, and any explanation of cancer in man must also explain the phenomena presented by cancer in the lower animals. These observations are uncontested and are of fundamental importance; they rule out of account the all too frequent pronouncements that cancer is a disease of civilization and can be abolished by a return to a "natural" mode of living—whatever that may mean.

In the literature of twenty years ago may be found papers in which doubt was thrown on the neoplastic nature of animal tumours, but the question has now been most thoroughly studied, and the opinion among those most competent to judge is that the animal tumours are true new growths. It is therefore no longer necessary to discuss the point at any length. It is sufficient to say that in mode of origin, in age incidence, in clinical course, in mode of growth and infiltrative spread, and in the formation of metastases, there are no differences between tumours of man and of animals. The same range of tumours, benign and malignant, is met with in animals, and it is with this material that the greater part of experimental studies have been carried on.

The method by which a tumour is transferred from one animal to another consists in the implantation, usually subcutaneously, of a fragment of the tumour by means of a trocar or a syringe. From the implanted fragment a new tumour arises. Is the new tumour produced by infecting the cells of the host, or does it arise by multiplication of the cells implanted? This question was studied by Jensen by the following technique. A series of animals—mice—was inoculated, in the manner indicated, with a mouse carcinoma, and at regular intervals one of the inoculated mice was killed, the whole of the graft and surrounding tissues fixed and cut in serial sections. In this way the fate of the implanted cells could be followed. Jensen showed decisively for a carcinoma—and his results have been confirmed by numerous observers—that the daughter tumour is derived entirely from the cells of the implanted graft. The central portion of the graft dies, but the peripheral cells live; the fate of the implanted stroma of the graft is difficult to follow, but a new stroma is provided by the host, and it is this which nourishes the rim of neoplastic cells of the implanted fragment. The process, then, is a true transplantation and not an infection. Loeb, who studied the same problem with a rat sarcoma, was unable to come to a decided opinion. He inclined to the belief that the new tumour was derived partly from the malignant cells inoculated and partly, by a process of infection, from the connective tissues of the host. This difference in finding, however, may be merely one of technique and depending upon the difficulty of recognizing a malignant from a normal connective tissue cell. Wherever the cells of the implanted tumour are easily distinguished from the cells of the area in which the fragment is placed, the question at issue may be determined by early-stage examinations. The general result of an immense amount of investigation of this character has been to show that the inoculations of tumours are true

\* Delivered at the Royal Infirmary, Manchester, November 9th, 1926.

transplantations, that the daughter tumours are derived from the cells of the original new growths, and that the inoculated animals merely act as a medium in which the cells proliferate. By losing sight of these fundamental facts and by regarding transplanted tumours as *new* growths cancer research has often been led into blind alleys.

The failure of the earliest investigators of cancer to transfer the human disease to lower animals has been mentioned already. This failure probably played a large part in forming the opinion that cancer is essentially a human disease. But it was quickly shown by experimental research that the tumours of animals are transplantable only within the species in which they occur. Thus a dog tumour cannot be propagated in a cat, or a cat tumour in a dog. In the light of the discoveries of experimental histologists this is easily understood. It has been shown that inoculations of tumours are transplantations, and therefore it could not be expected that the cells of a dog, for example, would grow indefinitely in cats or any other species of animal than the dog. The cell of an animal carries the species specificity. Certain observations have been made which would appear to invalidate this conclusion. Murphy discovered that mammalian tumours can be grown in a developing chick embryo. This discovery has been confirmed by many observers, including myself. From a minute fragment of a mouse carcinoma a considerable amount of growth can be procured, and the astonishing picture is obtained of mouse epithelial tissue growing rapidly around a stroma provided by the chick embryo, new blood vessels in which course nucleated red cells penetrating the mass of growth.

The same phenomenon of heteroplastic growth can be obtained in mammals by inoculating a mouse sarcoma into new-born rats. The cells proliferate and form a large tumour, which can again be transplanted into new-born rats. In this way it is possible to maintain a mouse sarcoma for several generations in rats. But such work has no real bearing on the cancer problem. The implanted cells remain mouse cells, and the maintenance of the tumour for a few weeks or months in a series of new-born rats is merely a laboratory trick which leaves the main problem unaffected.

Since daughter tumours are derived from the implanted tumour cells it follows that living cells must be inoculated in order to obtain a second tumour. With epithelial tissues this is obvious indeed; inoculations are usually made subcutaneously into the connective tissues, and the formation of an epithelial daughter tumour could not be expected to occur from infection of connective tissue cells. It is, however, an experimental fact that when the cells of a tumour are killed, whether by heat or by drying, by means of antiseptics or by mechanical disintegration, the mass of dead material no longer possesses the power of giving rise to a tumour when it is inoculated into a suitable animal. Thus, coincident with the death of the tumour cell, there disappears the power of inducing a daughter tumour. The fact fits exactly with the logical deductions from the histological analysis of the changes accompanying the processes of transplantation.

Such beautiful interlocking of fact and deduction served to strengthen the already strong conviction that the tumour cell is itself, as it were, the parasite. Nothing, apparently, is separable from the malignant cell which can induce the formation of a new tumour, and the general opinion has been reached, and is now held almost as a dogma, that the malignant cell is one which, under the influence of many possible inciting causes, has assumed a character or quality which enables it to grow and divide steadily and persistently beyond the needs of the rest of the body. According to this view the cell itself is a parasite. The position is most clearly indicated by the following facts. It is now possible by following the brilliant work of Yamagiwa and Ishikawa to induce tumours in rats and mice by repeated applications of tar to the skin or subcutaneous tissues. The tumours thus produced are typical new growths and behave in every respect like spontaneous tumours which are caused in some way which we do not yet understand. A tar tumour of a mouse—carcinoma or sarcoma—can be transferred by transplantation to other mice, but living cells

are necessary for success. It cannot be successfully transplanted to a rat or to any other species of animal. It is as much an individual mouse tissue as a mouse is an individual mouse. In the same way a rat tar-tumour can be transplanted successfully only to other rats, and only by the inoculation of living cells. We thus arrive at the interesting position that one and the same irritant acting upon two species of animals will induce new growths in each species, but the new growth in each case is individual and particular to its own species. Clearly the extrinsic agent, the tar, has induced an intrinsic change in the cell. It is thus easy to understand why a microbic hypothesis of the origin of tumours is met with scepticism and indeed contempt. It would be strange were it otherwise. Nevertheless, I believe that these apparently conclusive facts merely conceal the truth.

And now I come to the exceptions in all this mass of tumours. I refer to the well known fowl tumours described by Peyton Rous. For the purpose of simplification I shall describe and discuss only one of these tumours, the first to be discovered, and the one which is in the hands of pathologists all over the world. It is a spindle-cell sarcoma, of primitive type, which occurred spontaneously in a Plymouth Rock variety of the domestic fowl. The tumour was first described in 1910, when it was shown to be transplantable in the usual way, but to exhibit an unusual degree of specificity for the variety of bird in which it originated. Indeed, the early transplantations were successful only in blood relations of the fowl which bore the spontaneous tumour. Now, after many years of artificial transplantation, the tumour grows in almost any variety of fowl, but, like mammalian tumours, it retains its species specificity strictly—that is to say, it will not grow in pigeons, ducks, or any other species of bird, or in any mammal. Now this tumour was found by Peyton Rous to differ from all other tumours examined up to that time in being transferable to fowls, not only by means of living cells but also by means of dried tumour tissue or by means of cell-free filtrates. The cell-free filtrates, therefore, contain the tumour's "cause." And, most surprising fact of all, the filtrate is infective only for fowls, and causes the reproduction invariably of exactly the same kind of tumour—a spindle-cell sarcoma. Thus the agent derived from the tumour cells has the power of exciting the formation again of a new tumour by transforming the normal connective tissue cell of the fowl into malignant cells, and this power is exerted only in one species. It is easy to believe in the specificity of animal cells, but here apparently the specificity is freed from the cells and is obtained in solution—or at least it passes through a filter.

Of such tumours half a dozen or so have been described; but it does not matter much whether the number be half a dozen or half a hundred: the problem to be faced is the same and is challenging to all of us. Before trying to make clear what I conceive to be the problem, I will state and discuss briefly the essential facts upon which there is general agreement.

First, the tumour is a true new growth as judged by the most rigid standards; secondly, filtrates through candles which hold back very small bacteria are able to induce sarcoma formation; and thirdly, some of the properties of the filterable agent are those which we usually associate with living organisms.

The general reaction to the discovery of these tumours was one of surprise that such a tumour should exist, followed by a half-hearted denial of the neoplastic nature of the growth. To-day most pathologists who have studied the tumour agree as to its neoplastic nature. There exists, however, an unwillingness to consider seriously the possibility of the filterable agent being an ultra-microscopic microbe such as we believe exists in certain animal diseases. Some of the more absurd explanations of the peculiarity of this tumour I will simply mention. It has been suggested that the filtrate of the tumour contains an ultra-microscopic cell which, when injected into the muscle of a fowl, enlarges and becomes a normal cell from which the new tumour forms. A modification of this view which has been put forward is that the active filtrate contains a part of the cell from which the normal cell can again regenerate. Such views, I hope, need no reply. They are stated merely

# THE CANCER PROBLEM.

to indicate the extremes to which men will go to explain away a fact which runs counter to a strongly held opinion. Rous and his collaborators in their long researches into the filterable tumours came to the opinion that the balance of evidence was in favour of the agent being a living, filterable micro-organism. Now what is the evidence that such things exist at all? If we take the classical example, and the first discovered, of an animal disease believed to be caused by a filterable virus we shall consider foot-and-mouth disease.

The current belief that foot-and-mouth disease is caused by a filterable virus is founded upon the following evidence. When the vesicular fluid of a lesion in this disease is diluted and filtered through a good candle, and the filtrate is injected into a normal animal, this animal acquires the typical signs and symptoms of the disease. The vesicular fluid obtained from the second case may again be diluted and filtered, and so on *ad infinitum*. The filtrate when examined by ordinary microscopic and cultural methods is sterile; but since the causal agent reproduces itself indefinitely in the bodies of the inoculated animals it must be a living thing, and it is, as we have seen, of ultra-microscopic size. This evidence almost all bacteriologists believe that the cause of foot-and-mouth disease is an ultra-microscopic microbe. The evidence produced by Peyton Rous with regard to the filterable tumours was of the same kind and quality, and is now more extensive. But opinion against a microbe cause of tumours is strong, and few are prepared to accept for tumours conclusions which, on similar evidence, are unquestioned in other fields of medicine.

Let me now state the problem which is before all of us. Thousands of tumours of men and animals have been studied. Large numbers have been cultivated by transplantation. A considerable number of tumours have been induced *de novo* by means of chemical and other irritants, and have been carefully studied. Almost all attempts to find an extrinsic cause—or a cause separable from the cells—have failed. But for about half a dozen tumours, of various histological kinds, a cause, a filterable virus, separable from cells, has been found. We may regard the upon this astonishing difference? We may regard the filterable tumours as a disease sui generis unrelated to other tumours; in this way we must suppose that a filterable virus plays a part in the causation of certain tumours which is comparable to the part played by tar or soot in others. This attitude to the problem has been general, but I think that it is a mere evasion of a very real difficulty. The problem exposed by the work of Rous does not consist solely in the isolation and cultivation of a virus. The true explanation of these tumours must, in the first place, decide whether or not a virus is present; and in the second place, equally important from the point of view of the cancer problem, must give us some understanding of the extraordinary specific character of active filtrates.

For my part I agree most emphatically with Rous, Murphy, and Tytler that "the findings with the chicken tumours largely demolish the theoretical basis on which objections to an extrinsic cause for cancer have been built up." But can these positive findings of Rous be reconciled with the negative results of similar experiments made with the majority of other tumours? I think they can.

**The Filterability of the Rous Tumour.**  
It has already been pointed out that the exceptional character of the tumour lies in the fact that cell-free extracts are able to cause the formation of a new tumour. This property of the tumour must therefore be carefully studied, and we must know how far it is a fixed and constant property. It has generally been looked upon as constant, and the tumour has on this account been set in sharp contrast with the facts; they are not quite so simple. Peyton Rous remarked in one of his papers dealing with the filterability of his tumour that sometimes, and under the best conditions, cell-free filtrates are unaccountably innocuous. That, I am sure, has been the experience of all investigators who have worked for any length of time with the tumour. In my experience it has been unusual, for example, to obtain a potent filtrate from a tumour

which has been induced by the inoculation of dried tumour tissue, or from a tumour which has been caused by the inoculation of filtrates damaged by heat. But when failure to obtain potent filtrates is an irregular thing the most obvious explanation is that the failure is caused by some technical difficulty. Filtration is not a simple regular process, and it is easy to understand irregular qualities of filtrates. But it has now been shown that technical difficulties cannot fully explain such failures. Dr. Andrews and myself have described how a Rous tumour lost its property of filterability, and how this property remained absent for more than five months and then suddenly reappeared. During this long period the tumour was transplantable only by means of living cells—that is, it behaved like the recognized tumours of mammals. Clearly, then, this property of filterability is not fixed; all we can say is that generally a filtrate of the tumour is active—sometimes feebly, sometimes intensely; often it is quite inert. And since it has generally been accepted that a potent cell-free filtrate contains the cause is present in the filtrates to say that sometimes the cause is present in the filtrates and sometimes it is not? The solution of this apparently ridiculous dilemma will be shown later; at present I merely wish to point out that sometimes the tumour's cause gives no sign of its presence.

## The Effect of Heat on Filtrates.

It was shown by Rous and Murphy that tumour extracts are always robbed of their activity by exposure to a temperature of 55° C. for fifteen minutes. This statement I can confirm completely. It has been tested very carefully, and the method employed is as follows: Not more than 3 c.cm. of the tumour extract is sealed up in a thin-walled, hard-glass test tube, which is then attached to the bulb of a standard thermometer and completely immersed in a water-bath kept at 55° C. The thermometer and attached tube are shaken gently during the period of heating. Tested in this way, tumour extracts, whatever their initial potency, are invariably inactivated. Rous and Murphy regarded this result as evidence that the causative agent of the tumour had been destroyed; and of course it looks very like it. Whatever the agent is that is destroyed in such a short time at 55° C. it is evidently very sensitive to heat, and judging by the effect of lower points of other viruses, it is not likely to be a virus. This view is supported by a study of the effect of lower temperatures than 55° C. upon a series of filtrates of tumours. A filtrate, usually through a Mandler candle, was made from all the routine tumours obtained during a period of more than six months—in all more than 60 tumours. Each filtrate was tested at temperatures from 45° to 55° C., variations being made from time to time. During the period chosen the tumour was not malignant, and as malignancy and activity of filtrates parallel with one another, the filtrates were not very potent. In a few tests made, it was found that 0.5 c.cm. of Mandler filtrate was barely sufficient to induce a new tumour; 2 c.cm. was in each case adequate. All the samples of such filtrates were inactivated by exposure to 55° C. for fifteen minutes; often 50° C., and sometimes the tumour became exceedingly malignant, metastasizing freely in liver, lungs, spleen, and elsewhere, and the filtrate became exceedingly active, inducing tumours in doses of 0.001 c.cm., then it was found that 54° C. for fifteen minutes was insufficient to destroy all activity—the activity of the filtrate being merely reduced—but that exposure to 55° C. for fifteen minutes was effective. It is evident from this experience that the substance in the filtrate which is sensitive to heat is variable in amount or in quality in filtrates from different tumours.

## Effects of Antiseptics upon Tumour Extracts.

One of the reasons given by Rous and Murphy for their belief that the filterable agent may be a virus was that antiseptics destroy the agent. It is only fair to state that Dr. Murphy has since changed his mind; he now thinks that it is unnecessary to assume a virus. His opinion of 1912 seems to me to be sounder than his opinion of 1926. Carbolic acid, corrosive sublimate, toluene, chloroform and

ether, hydrogen peroxide, formalin, acriflavine and hydrocyanic acid are some of the antiseptics which have been tested, and they are all effective, each in its own way, in abolishing the activity of tumour extracts. I shall describe briefly the effects of two only of these substances—namely, chloroform and acriflavine.

Chloroform acts very rapidly at incubator temperature. This is shown very clearly in Chart 1, which represents the effect of 0.2 c.cm. of chloroform on 10 c.cm. of clear, cell-free, sand filtrate of a very malignant Rous sarcoma. The mixture of filtrate and chloroform was incubated in a large hard-glass tube in a water-bath at 37° C. After incubation for one hour a sample was removed, the chloroform pumped off, and 1 c.cm. then inoculated intramuscularly into the right breast of Bird 411; after two and a quarter hours a second sample was inoculated in a dose of 1 c.cm. into the left breast of the same bird; and after three hours 1 c.cm. was inoculated into the right leg of the bird. The control in this experiment was provided by incubating 10 c.cm. of the filtrate, contained in a hard-glass tube, for three hours in the same water-bath; of this incubated extract 0.2 c.cm. was inoculated into the left leg of Bird 411. It is shown by this experiment that in two and a quarter hours the activity of the filtrate has been enormously diminished by the chloroform; in three hours abolished. But since the fowl died in nineteen days it might be argued that there was not sufficient time allowed for the dose of filtrate treated with chloroform for the full three hours to manifest its activity. To provide against such a source of error a second fowl was inoculated with 2 c.cm. of such extract; in four months it has not developed a tumour.

Thus chloroform acts very rapidly. This, however, applies only to the ordinary impure chloroform used for common purposes in laboratories. When pure chloroform is used the action is much slower. I am indebted to Dr. Howard Mueller of Harvard for the intimation that this might be so.

Acriflavine acts slowly. The experiment represented by Chart 2 illustrates this very well. It will be seen from this that 1 in 5,000 acriflavine is unable in three hours to abolish the activity of an extract of a tumour. When such experiments are carried on for longer times—for example, six hours—it is found that the activity is further diminished but not entirely abolished. In order to inactivate a filtrate it is necessary to incubate the mixture overnight, and this often introduces a complication: simple incubation at 37° C. for eighteen hours frequently robs a filtrate of its power to induce tumour formation. In order, therefore, to utilize the action of acriflavine in experiments of an analytical character it is necessary to devise other methods the details of which are omitted here for the sake of clarity.\*

#### *Two Factors: Both Necessary for Cell Infection.*

We know that filtrates of the Rous tumour can be inactivated by heat and by antiseptics. By means of experiments such as that illustrated in Chart 3 it can be shown that the element destroyed by heat is not the same as that destroyed by acriflavine. The experiment shows that a tumour extract treated with acriflavine was quite inactive; an extract of the same tumour heated to 55° to 56° C. for eighteen minutes was also inactive. The two inactive fluids when mixed together acquired the power of inducing tumour formation.

The only criticism which can be passed upon experiments of this kind is that the chickens inoculated with acriflavine-treated extract happen to be naturally resistant, whereas the others are sensitive. This criticism, however, is not sound. The percentage of resistant birds cannot be determined absolutely, but it is, in any case, very small. Moreover, resistance is a graded quality. When the infective fluid is intensely active it is very rare to find a chicken resistant to its action. Only when the fluids which are inoculated are on the border-line of infectivity does one reveal differences in sensitiveness among any batch of chickens. The criticism, in any case, cannot

apply to the next series of experiments, which are illustrated in Charts 4 and 5. In these experiments the same bird is used as control to the experiment. In the first experiment (Chart 4) the dose of acriflavine-treated tumour extract is the same in both breasts; the only difference between the two sides is that in the right breast the diluent is horse-serum broth medium, while in the left breast it is heat-inactivated extract of tumour. The quantities in such experiments as this are measured with the most scrupulous exactitude.

In the experiments represented by Chart 5 the controls, both of heat-inactivated and antiseptic-inactivated extracts, are included on the same bird. Similar experiments, with similar results, have been made with chloroform and with hydrocyanic acid as antiseptics.

From results such as these I am satisfied that the production of a tumour with cell-free filtrates depends upon the conjoint action of two elements of the filtrate. One of these is rendered inactive by acriflavine or other antiseptic, and is therefore presumably a micro-organism; the other is readily inactivated by heat. As we have seen, it would appear probable that the agent which is destroyed by heat is variable in quantity (or in quality) in filtrates from different tumours.

Chart 6, which illustrates eight similar experiments, shows that innocuous filtrates (that is, filtrates from a "non-filterable" Rous tumour) have the same property of reactivating acriflavine-inactivated extracts as have extracts which have been heated to 55° C. for fifteen minutes. It follows that inert filtrates are simply filtrate which contain none, or an insufficient amount, of this heat sensitive but absolutely essential factor. This factor—which I have named the "specific factor," for reason which will appear later—may be present in variable amount, and it is only because of its activity that the presence of a virus can be shown in the Rous sarcoma. When it is absent the Rous sarcoma, like the average bird and mammalian tumours, cannot reveal its "cause." The peculiarity of the Rous tumour is that it manufactures in varying degree this accessory thermo-labile substance.

It is evident from these experiments that the agent which is destroyed by antiseptics (the virus) is unable acting alone, to induce sarcoma formation. This fact appears to me to be very simple. It has its analogies in general bacteriology, where the phenomena are more widely known and appreciated. But the fact, when established in research connected with the subject of cancer, is apparently regarded as a diabolical mystification of a plain and straightforward problem. It is but right to state here that Professor Borrel, the pioneer of experimental cancer research, has for twenty years held the opinion on general grounds that the essential cause of tumours is a virus which requires prolonged preparatory irritation of the tissues before its latent powers can be manifested.

The use of the word "cause" in medicine is unfortunate and is always liable to misapprehension. What is generally understood by the word is, I assume, a factor which must be invariably present in the etiology of a disease. We cannot, if this be the meaning understood, regard the specific factor as the cause of the Rous sarcoma, because it is sometimes absent. The virus—that is, the element which may be destroyed by an antiseptic—is, so far as my experiments show, always present in the tumour whether the tumour be very malignant or relatively benign. I regard the virus, therefore, as the cause of the sarcoma. Which of these two characters carries the specificity?

#### *Substitution Experiments.*

If an extract of the Rous fowl sarcoma be inactivated by heat and then there be added to it an extract of another tumour, the mixture does not induce sarcoma formation in the fowl or in the animal from which the second tumour was obtained—that is, a heat-inactivated extract of the Rous sarcoma cannot be restored to activity by the addition of simple extract of a rat or mouse tumour. But when an extract of a Rous sarcoma is inactivated by means of an antiseptic or by centrifugation, the activity can be restored by the addition of extracts of some other tumours.

\* The details and protocols of these researches will appear in a series of papers in the *British Journal of Experimental Pathology*.

CHART 1.

CHART 2

Chart 7 shows this very clearly. In this experiment the fowl sarcoma filtrate was treated with chloroform, the chloroform removed, and 1 c.cm. of the filtrate was then injected into the right breast of a fowl. Into the left breast of the same animal a mixture of 0.5 c.cm. of this chloroform-inactivated filtrate and 0.5 c.cm. of an extract of a tar tumour of the mouse was injected. A tumour grew in the left breast; the right breast remained quite negative. Chart 8 shows the same result for a human breast carcinoma.

Experiments such as these have been made with a large variety of tumours and with normal tissues. Among the tumours which have provided an agent which can replace

CHART 3.—All injections July 27th, 1926.

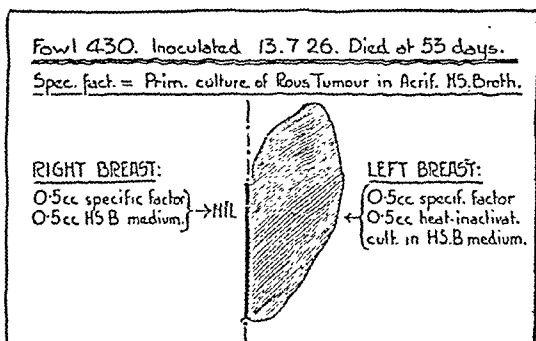

CHART 4.

CHART 5.

that agent of the Rous sarcoma destroyed by antiseptics are carcinomata and sarcomata, both of man and animals. Normal tissues which have been tested are: embryonic tissues (chick, mouse, rat) more than 150 times; adult tissues of animals, including heart, lungs, muscle, brain, liver, and kidneys—and, in one instance, normal human uterus. Not once has it been possible with extracts of such normal tissues to replace the agent destroyed by antiseptic in the fowl sarcoma extract.

My interpretation of such experiments is as follows: In the experiment represented by Chart 8, for example, acriflavine has destroyed in the Rous tumour extract a micro-organism; this interpretation is in accordance with the

well known antiseptic action of acriflavine. The extract of mammary carcinoma has, as I conceive it, provided a fresh supply of organisms which are able, in virtue of the presence of a sufficient amount of accessory factor of the fowl tumour, to infect the cells of the fowl inoculated.

These experiments show very clearly that the specificity of the Rous tumour extract is carried by the heat-labile

is a criticism which has been applied, and quite fairly, to these results: it is that possibly we are here dealing with a phenomenon similar to that discovered by Twort and now known as the "bacteriophage phenomenon." It is possible to argue that successive inoculations into tubes which contain living embryo induce repeatedly the production of the agent from the cells of the embryonic fragment. This is not impossible, but it is very improbable. It must, of course, be settled before the last element of doubt has been removed.

### Conclusions.

Does this new knowledge bring us any nearer to the solution of the problem set forth at the beginning of this lecture? And further, is the answer compatible with the known facts of cancer structure and behaviour?

It seems to me, after considering the problem very thoroughly—and I hope with a sound knowledge of the accepted facts—that in the first place there is no incompatibility between new and old "fact"; and in the second place it shows that there is an agent contained in tumours of diverse origin and of diverse structure which has the supremely important property of reactivating an extract of the Rous sarcoma which has been inactivated by means of an antiseptic. The tumours in this respect are therefore linked together in a way which had never before been suspected; they are, indeed, a natural group. The agent which is common to these and which links them together

CHART 6.

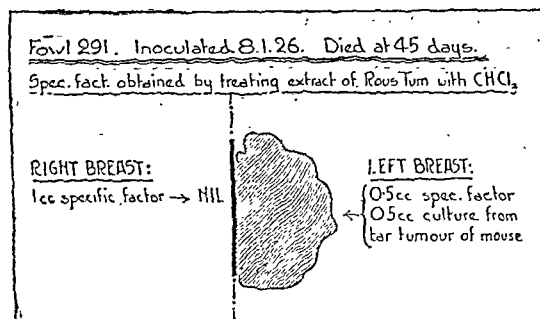

CHART 7.

CHART 8.

agent, which has, for this reason, been called the "specific factor."

It has already been pointed out that extracts of normal tissues do not provide the agent which reactivates antiseptic-treated extracts of the Rous sarcoma. But certain tumours, one of which is a sarcoma of the mouse, have so far invariably failed also. This is one of the most puzzling facts yet met with, and I have no explanation which accounts for it satisfactorily.

The evidence that the agent which is extractable from many bird and mammalian tumours, and which has the power of restoring activity to inactive extracts of the Rous tumour, is a micro-organism is as follows: first the agent is killed by antiseptics, and secondly, it can be cultivated. The proof of cultivation is obtained by the method described in a recent publication—namely, by using as a medium serum broth to which is added a fragment of embryonic tissue. Chart 9 shows the method of experimentation adopted. Acriflavine-treated extract of Rous sarcoma is prepared; to measured portions of this are added in series: (1) a sample of serum-broth-embryo culture medium, (2) a sample of a subculture in the same medium, and (3) samples of a subculture in different media. Quantities are measured precisely. The result of the experiment represented by Chart 9 shows that the agent from a rat carcinoma survived in horse-serum-broth-embryo and in horse-serum broth, but not in broth-embryo; it was not present in the horse-serum-broth control tube, which had been incubated for the same period of time as the cultures. Continuing with subcultures in this way, tumours have been obtained with remote (seventh) subcultures in media which contain embryo tissue. But there

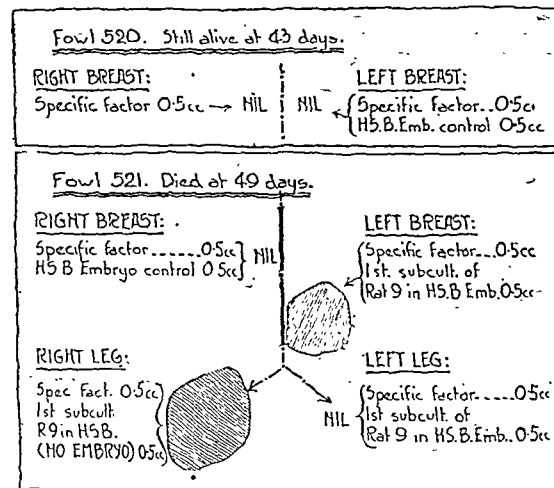

CHART 9.—All injections September 20th, 1926. Primary culture of Rous, in acriflavine. HS.B.=Specific factor.

in a group is killed by antiseptics and can be cultivated. Moreover, under special conditions it can be seen and photographed, as has been shown by my friend and colleague Mr. Barnard. I am satisfied that the simplest explanation of these observations is the correct one—namely, that the agent is a living, filterable microbe, and that it is the cause of new growths.

## THE RECONSTRUCTIVE SURGERY OF THE HIP.\*

ABSTRACT OF THE BRADSHAW LECTURE.

BY

ERNEST W. HEY GROVES, M.S., F.R.C.S.,  
PROFESSOR OF SURGERY, UNIVERSITY OF BRISTOL.

THE hip-joint, the largest and most important in the body, presents special difficulties and special displacements. It is more liable to serious disease and congenital dislocation than any other joint. Possibly this may be due in part to the evolutionary change from the quadruped to the biped gait and progression.

### FRACTURE OF THE NECK OF THE FEMUR.

Fractures of the true neck of the femur—that is, of the bone proximal to the intertrochanteric line—present very special features. Unless impacted these fractures never undergo natural union, and yet if artificial impaction is brought about, bony union will occur just as certainly as in any fracture elsewhere. Non-union, which is the natural event in these cases, is due to four causes—namely, want of apposition, poor blood supply, interposed capsule, and the action of the synovial fluid. Of these, the first two are by far the most important. If efficient treatment is delayed for more than a few weeks marked atrophy occurs in the proximal fragment, and after such an event perfect restitution either of form or function is impossible. The three essential points in the treatment are: early intervention, accurate apposition, and firm fixation. If these points are observed, firm bony union can be secured in practically all cases, whether in old or young.

The method advocated by Whitman is a great advance on previous modes of treatment. Under an anaesthetic the leg is pulled downwards, inverted and abducted, thus impacting the fracture. The abducted limb is fixed in a plaster spica for three to six months. The objections to this method consist in its uncertainty, and the very great torture and tedium of keeping an adult in a plaster case for several months. The uncertain result is due to the facts that manipulation of the leg cannot correct a misplaced proximal fragment, or get rid of that portion of the capsule which may lie between the broken surfaces.

Fixing the fracture by means of a bone peg gives a much more certain and perfect union with less strain upon the patience and fortitude of the patient. The joint is exposed by an anterior incision, the capsule opened, the fractured surfaces laid bare, the fracture accurately replaced by manipulation, and a square peg  $4\frac{1}{2}$  in. long by  $\frac{3}{8}$  in. thick driven from the base of the great trochanter through the neck into the head. The limb is put up in moderate flexion and abduction, steadied by slight traction. In six weeks' time the patient can walk with a calliper, and in three to six months can resume a normal life.

Special modifications of the pegging operation are useful in certain circumstances.

The peg may be inserted from above. This is useful when the proximal fragment is very small and the line of fracture difficult to expose outside the hip socket. The head of the bone is dislocated and nailed on to the neck, after which the bone is replaced in position.

In old cases, where the fracture is of long standing, it may be useful to employ a living bone peg, taken preferably from the fibula, because this type of peg will substitute some new bone in place of that lost by atrophy.

The peg may be inserted blindly—that is, without exposing the joint at all. This method should be reserved for patients whose age or debility makes it desirable to avoid the more serious operation. The drill hole into the neck and the insertion of the peg should be made under the guidance of the x rays. Conditions of slipped epiphysis should also be treated by the pegging operation, which is capable of restoring the bone to its perfect original form.

\* Delivered before the Royal College of Surgeons of England, November 11th, 1926. The full text of the lecture will be published in the January number of the *British Journal of Surgery*.

### ANKYLOSIS OF THE HIP.

There is no entirely satisfactory method of treating an ankylosed hip. It is comparatively easy to cure the patient of pain and to correct deformity, but it is extraordinarily difficult to secure mobility and stability at the same time, therefore only those cases are operated upon in which double ankylosis of the hips or simultaneous ankylosis of the hip and knee makes some treatment imperative. The more complicated methods of arthroplasty tend to leave the patient with a very stiff hip. It seems better, therefore, to be content with some modification of excision of the head of the femur. Two suggestions are made in order to secure both mobility and stability after this excision. To attain mobility, the capsular ligament is used as an envelope for the cut neck of the femur. To prevent the bone becoming dislocated the excised head of the femur is cut into two fragments and affixed to the upper margin of the acetabulum.

### CONGENITAL DISLOCATION OF THE HIP.

It is now generally recognized that early cases of congenital dislocation of the hip can be efficiently treated and cured by manipulation. But it is not realized that in older children when manipulative reduction is impossible a great deal can still be done by open operation to get firm and useful hip-joints. It is worse than useless to employ elaborate and difficult methods of manipulative reduction in these older cases. The main obstacle to reduction is the tight constriction of the capsule. No force or cunning can compel the head of the femur measuring one inch in diameter to pass through a thick constricted capsule presenting a channel of about a quarter of an inch.

Open exposure of the joint through an anterior incision makes it quite easy to reduce the dislocation after the constricted capsule has been slit open. The problem then arises as to the best methods of retaining the femur in its socket. In one method the acetabulum is deepened until it affords a socket sufficient to take the whole femoral head. This gives a very secure joint, but one which is liable to become stiff. In another method, that which has been most frequently used, the cartilage of the acetabulum is left undisturbed and a new rim is added to the socket by turning down a part of the outer surface of the iliac bone. In a third method the capsule is cut from its attachment to the pelvis and tied round the head of the femur, the acetabulum is gouged out, the head of the bone wrapped in the capsule is placed in the socket and anchored there by stitches which fix the capsule to the floor of the acetabulum.

In the late or adult cases of congenital dislocation a great deal can be done to cure both the pain and the lameness by a subtrochanteric osteotomy, putting up the leg in full abduction. But this is only suitable for unilateral cases. When the dislocation is bilateral, the head of one femur can be brought down into the socket by removing about two inches of the shaft of the bone below the small trochanter. This will give a firm hip on one side and the two legs will be of the same length. At a later date, if necessary, an osteotomy may be done on the opposite side.

### INFANTILE PARALYSIS AFFECTING THE HIP MUSCLES.

Extensive infantile paralysis of the lower limb can to a large extent be made good by means of apparatus which fixes and controls the knee and ankle joints, but paralysis of the gluteal muscles leads to a complete inability to balance the trunk upon the leg and necessitates the permanent use of crutches. It has been suggested that the lost abductors may be replaced by using the tensor fasciae femoris or the erector spinae muscles. Neither of these muscles singly can make a very efficient abductor, partly because one lies in front and the other behind the required line of action, and, in the case of the back muscle, because of the difficulty in getting a necessary tendinous insertion. By combining these two muscles an efficient digastric abductor of the hip is formed. A long incision is made on the outer side of the thigh; the ilio-tibial band is isolated and cut above the knee; the fascial band forming the tendon of the tensor muscle is brought backwards through the base of the great trochanter; the erector spinae muscle is exposed by a vertical incision, and the lower portion

isolated by cutting through its lower origin and splitting this part of the muscle upwards for about four inches; the ilio-tibial band is brought backwards and upwards through a tunnel under the skin and fixed to the isolated part of the erector spinae muscle.

#### SECTION OF NEUROLOGY AND PSYCHOLOGY.

E. FARQUHAR BUZZARD, M.D., F.R.C.P., President.

#### DISCUSSION ON MANIC-DEPRESSIVE PSYCHOSIS.

##### OPENING PAPER

BY

EDWARD MAPOTHER, M.D., M.R.C.P.,  
Medical Superintendent, Maudsley Hospital, London.

THE task of introducing for discussion the subject of the manic-depressive psychosis has an engaging but spurious air of simplicity. The disorder arouses a natural sympathy and interest in normal people. The anomalies of the patient have none of that apparently meaningless and inexplicable quality which makes the schizophrenic so remote and renders so improbable the truth that he once thought and acted like ourselves. On the contrary, if the term "manic-depressive psychosis" is used in any but the narrowest sense it is obvious that in many cases we are dealing with a merely quantitative deviation, that the disturbance consists in a response similar in kind to that which like circumstances might provoke in us, but morbidly prolonged or disproportionate or disastrous in degree. Even if we were to confine the term to those cases showing apparently spontaneous mutations of mood and activity there are few of us without personal experience of analogous phases.

In handling the practical problems of causation, diagnosis, prognosis, and treatment it is impossible to be both comprehensive and detailed. I shall aim at raising points for discussion, but if at times I express myself dogmatically I hope this will be recognized as merely provocative.

##### *Delimitation of Manic-Depressive Psychosis: Relation to Neuroses.*

The primary problem is what meaning should be attached to the term "manic-depressive psychosis." There is no constant and specific cause, and no distinctive bodily change recognizable during life or after death. The range of the term is a matter of convention: at present there is no agreement, and no one with the authority to impose one. Yet all discussion, at least as to the problems of causation, diagnosis, and prognosis, must depend on delimitation. All would probably agree that under the heading of "manic-depressive psychosis" are included cases of functional mental disorder which show as their predominant features one of a contrasting pair of anomalous types of reaction.

I. The depressive reaction comprises (a) Morbid dissatisfaction (with the self or circumstances) in one of its varieties; colouring of thought and action thereby; persistence or hyperexcitability of various alternative reactions (psychomotor and visceral) expressive of the mood. (b) A sense of difficulty in thought, action, and feeling of all other kinds and a varying true incapacity for activity in relation to external reality.

II. The manic reaction comprises: (a) Morbid satisfaction (with the self or circumstances); colouring of thought and action thereby and objective expressions of this mood. (b) Fallacious sense of power and mis-directed hyperactivity.

The question, however, which immediately arises is

whether all or only some such cases should be included; whether it is necessary to limit the application of the term by reference to varieties of these symptoms, their intensity, time relations, and causes, or by such criteria as insight and amenability to treatment. It will be generally agreed that subdivision in virtue of details of the known (for example, of past course and present symptoms) serves little purpose unless the types discriminated are correlated with differences in the unknown—for example, in causation, prognosis, or treatment. The term originated in the attempt of Kraepelin to establish a correlation between certain syndromes and course, between transverse and longitudinal section in the severer psychoses. Hence Kraepelin's invention of the category manic-depressive psychosis as one of the standard types to which cases of grave mental disease more or less conform.

It was emphasized that cases of the manic-depressive type did not in most instances tend to dementia between attacks or even after a number of such. It is doubtful whether this is more than a truism which could be briefly expressed in more modern terms by saying that in a given patient there is no strong reason to anticipate marked and terminal schizophrenia in the absence of minor and early changes of the same kind. Nevertheless cases presenting the manic-depressive syndrome in absolutely pure form during their early stage do sometimes end as typical dementia praecox.

In earlier years spontaneous occurrence—that is, lack of traceable relation to any external causes—was one of the features ascribed to typical manic-depressive psychosis, but in fact the degree to which internal and external factors co-operate is infinitely variable.

It is unproven and improbable that any mental syndrome is due to a specific cause, and consequently there is no more likelihood of a constant course in mania or depression than in jaundice.

Kraepelin himself in later years has fully recognized that in addition to the striking cases of almost purely affective disturbance reaching the intensity to which we commonly give the name of a psychosis and showing a clear-cut phasic course there are many others. We see cases in which chronic anomalies, like in kind to those of the attack though varying infinitely in degree, are present before or after. These cases merge into those where constitutional symptoms of one kind or the other are pretty constantly present and undergo mere fluctuations. Thus there is a complete gradation to certain minor disturbances which whether continuous or phasic, are usually termed neuroses.

Kraepelin, if anyone, has the right to settle what conditions the term "manic-depressive psychosis" shall connote. He has come to the conclusion that it is simplest to include all cases showing the affective excesses and also the "syntonic" types of intellectual and conative disorder to which I have referred, and this regardless of their intensity and time relations. He has not been followed by all who have borrowed their names and ideas from his earlier work, but personally I entirely agree with his later views in this matter.

The distinction between what are termed neuroses and psychoses has really grown out of practical differences, particularly as regards certification and asylum treatment. It has become customary to call those types and degrees of mental disorder which rarely call for such measures by the name of neuroses. I can find no other basis for the distinction; neither insight, nor co-operation in treatment, nor susceptibility to psychotherapy will serve.

I am aware that this view will probably be challenged. There is a small group who insist on importing animism into psychopathology. Most of these authors seem to propound the paradox that mental disorders are disturbances in the nervous functions and structures, while what we term neuroses are disturbances of an entity called mind without persistent physical basis, though others, including McDougall, would, I believe, include manic-depressive psychosis in the latter category. In spite of the profoundest respect for those who hold these theories, and in spite of the traditional upbringing during childhood, I confess that these views now convey no meaning to me. We admit the mystery of consciousness, but to assume that an enduring physical basis for habitually abnormal behaviour is probably non-existent because at present its exact nature is not

# MANIC-DEPRESSIVE PSYCHOSIS.

demonstrable seems to me a flat defiance of all relevant experience in medicine.

The view that neurosis and the depressive psychosis are continuous, and that both are associated with lasting bodily anomalies, is not, of course, in the least inconsistent with believing that the traces of unpleasant experience are one of the principal causes of both, and that other mental experiences may be curative. It is in fact a wider and less degree of clinical blindness to ignore the fact that in a very large proportion of the attacks of depression and melancholia, and as a rule the exact emotional anomaly corresponds to a morbid protraction of what the circumstances would naturally cause. Often there remains undue susceptibility to the same emotion—for example, after one attack of anxiety with fairly adequate reason, a liability to terror from all sorts of trivial causes. Frequently one finds the topic of the first attack reproduced in later ones, though there is nothing common in the patient's circumstances at the two dates except his mood. Many cases, even in the first attack, show regressive prominence of events of the early life, tinged with the same emotion.

On the other hand, events justifying one depressive emotion—for example, grief—may cause relapse of another somewhat different depressive type—for example, fear, to which the patient has become habitually liable. Attacks of mania and melancholia are very often obviously decontrol of tendencies just inhibited when the patient is at his best. On the other hand, many attacks of acute mania are clearly that all mania is of this type, catastrophie. It is arguable that all mania is of this type, even when hypomania is temperamental. The phenomena seen in manic-depressive psychosis and allied neuroses are obviously related to those of habit, decontrol, and contrast, as otherwise exhibited in the nervous system. In view of this it seems to me a counsel of despair to urge contentment with conceiving them in terms of struggles between such entities as the conscious and unconscious mind except as a temporary expedient.

## VARIATION OF THE DEPRESSIVE SYNDROME.

(a) *In Ratio of Positive and Negative Symptoms.*  
In the depressive type of psychosis there is great variation in the ratio between the excess of affective response and the reduction of conative and intellectual activity in relation to the outer world. In many cases, at least in some depressive attacks, these negative symptoms are the salient feature. This state of things reaches its height in anergic stupor. At the beginning or end of an attack it is common to find as the main symptoms of unreality, contraction and of recollection, loss of interest and pleasure in life and of all enduring feelings, a sense of unreality of the world and strangeness of the self, lassitude, fatigability, and hatred of effort and responsibility. All these may be accompanied by perfect insight; usually there is some tendency to exaggerate the objective disabilities, but insight even into this tendency.

Many neuropaths show this syndrome in a single attack, repeatedly or chronically, and never exceed it. It then seems to correspond to what may best be included under the overstrained heading of neurasthenia.

## (b) *In Type of Emotion.*

When depression is well marked its exact form varies greatly—grief finding causes for unhappiness in the past, fear which seeks them in the future, and a simple sense of wretchedness about the present seem the primary types. The melancholic is, of course, apt to experience all these varieties of depression; which type predominates seems in part a function of recent circumstances, if any, precipitating the present attack or the first of his life. In part, the mood expresses the individual temperament as determined by the interaction of inborn constitution with the sum of experience, remote as well as recent.

Anxiety neurosis has achieved a persistent acceptance to its causation. There seems no particular objection to isolating it if it be regarded as merely one of the numerous subdivisions of the manic-depressive group. But it merges

in the same patient, and by a perfectly continuous gradation in a series of patients, into agitated melancholia. Almost as much could be said for recognizing grief and wretchedness neuroses. It would be easy to construct a table of symptoms analogous to those seen in anxiety neurosis, but coupled with grief and associated with insight into their morbid nature. We have all seen the patient exasperated by tears for which he can ascribe no cause; and obsessed by sorrowful memories despite the fullest recognition of the futility of dwelling on these. Remorse, which provides at once a reason for depression past, present, and future, is about the commonest form.

(c) *In Intellectual Concomitants.*  
Grief, misery, or fear is apt to make the patient remember events, magnify perceptions, and anticipate prospects that are in keeping with itself. Insight is not only graded in various patients, but also varies immensely from time to time. It includes insight into the morbidity of the emotions and of the rationalizations to which these incline the patient. In a surprising number of even the severest cases of melancholia there are no delusions, merely a formless sense of one of the three types of distress which I have mentioned. Hallucinations and delusions in the melancholic are usually related to a foundation of fact, though it may be a frail one; they show chiefly a distorted sense of proportion and probability. Often there is merely a regressive prominence of some congruous memory without delusion. Obsessions are common in these cases, but, like the delusions, are as a rule of the readily intelligible type.

(d) *In Psychomotor Accompaniments.*  
Grief, wretchedness, and fear in the melancholic may alike find expression in mute prostration or in various forms of futile activity, exaggerating those seen in the normal affected by similar emotions. Such differences have formed the basis of much traditional subdivision of melancholia—for example, into agitated, resistive stuporose, and so forth. The one patient is apt to vary in the course of a day in these respects.

## Transition between Manic-Depressive and other Syndromes.

Next we must recognize that cases which are mainly manic-depressive may from their beginning present certain features resembling dementia praecox or come to develop these. Other types of reaction than the schizoid may be combined with the syntonie. One may see the typical failure to recognize the outer world and liability to hallucinations may also coexist in varying measure with either mania or melancholia. In either case hostility is the keynote. The distinction from the simple melancholic reaction consists in the attitude to misfortune—acceptance as retribution or ill luck in the one, and resentment as injustice in the other. Modern psychiatry is at last losing its passion for multiplying descriptive categories, which has been so often parodied. We are moving towards a recognition of the fact that the task of psychopathology is to isolate a few fundamental types of anomalous reaction for which a physical basis can be sought. Among these are the two syntonie types, the confusional, the schizoid, the paranoid, and the hysterical. These are not regarded as separate diseases comparable with measles and scarlet fever, or with tabes and disseminated sclerosis. Each may result from numerous causes, and generally does result from a combination which can give rise to several anomalies of reaction, and often initiates a mixture of them in one patient.

## Physical Basis of Manic-Depressive and other Functional Psychoses.

It is at least conceivable that some of the primary modes of abnormal mental reaction correspond to fairly definite bodily changes, perhaps to particular systems of neurons which we shall some day be able to identify. The combination of more than one type of anomaly in most cases would then be somewhat analogous to in tabo-paresis. Attempts to conceive the physical basis of the various reaction types are of course purely speculative, but recognition of their nature at least saves us from the misleading

simplification called "making a diagnosis" as between various functional psychoses and neuroses. This does not exclude the possibility that the degree in which various reaction types are present may be empirically correlated with certain courses.

Such evidence as there is regarding the physical basis of dementia praecox and manic-depressive psychosis supports the view which I have put forward. Most of the earlier changes described in both are not peculiar to any disease, but accompaniments of the behaviour or emotion displayed, or secondary results of these. Such will, of course, be seen alike in manic-depressive psychosis and dementia praecox. Among these may be instanced the loss of weight due in many cases to insomnia, restlessness, and starvation, glycosuria, which may occur with all forms of normal or morbid excitement; and leucocytosis of the type associated with exercise. Blood pressure also is probably parallel to mood and behaviour.

Numerous physical changes have been described of late years by Sir Frederick Mott and Dr. Golla, and by Dr. Tabella Robertson working with them in the Maudsley laboratory, as occurring in the functional psychoses, which seem independent of behaviour. They are found in manic-depressive types as well as in dementia praecox. These changes include histological ones in the cortex cerebri, gonads, adrenals, and pituitary body. Specific relation to the functional psychoses seems fairly certain (though it has been denied), but differences between manic-depressive and dementia praecox are only questions of constancy and degree. This agrees with clinical facts such as that amenorrhoea is common in both. It is opposed to the alleged finding in dementia praecox alone of protective ferments against breakdown products of cerebral cortex and gonads by the Abderhalden reaction; but the value of these findings is very doubtful. It is likewise true that such intra-vitam reactions as the haemoclastic crisis, absence of the alkaline tide, abnormalities in composition of the alveolar air after food, in gastric secretion, and in blood sugar, are common to both. Changes in basal metabolism peculiar to dementia praecox and in nitrogen excretion peculiar to manic-depressive have been described, but difficulties of technique make these results very questionable.

#### *Etiology of Manic-Depressive Psychosis.*

The problem is really the double one of tracing separately an exciting cause and a predisposition or susceptibility.

Of exciting causes shock in the absolutely normal is rarely sufficient, but even if we confine our attention to cases of certifiable severity a recent serious mental stress to which the attack is really traceable is found in quite 50 per cent. Probably the proportion would be much higher if slight cases were considered. In saying this I have due regard to alleged causal episodes that are symptomatic or results of the psychosis or coincidences or commonplace or merely untrue.

I hesitate to refer to such banalities as exciting mental stresses in these days when the quest of the obscure and the terror of the obvious has become a cult; when nothing can be too trivial to be of revolutionary importance if only it be sufficiently remote. Of these banalities the death of husband or wife seems far the commonest to me, probably because of the usual age of occurrence. Financial worries come next, and are often combined with the former cause. More romantic episodes, such as disappointment in love and illicit pregnancies, are a bad third. The insanity of a near relative is a very common determinant in my experience. I have seen seven instances in the last three years where sudden development of insanity in one patient has been followed by melancholia in a brother or sister, or in a husband or wife. This seems by far the commonest type of *folie à deux*.

Though shocks are more potent, I think the modern fashion of minimizing intellectual overwork as a cause of mental illness has gone too far, but separation of this from worry is generally more theoretical than real. As one would guess from experience of ordinary humanity, performances that might reasonably cause shame are less prone than misfortune to originate melancholia, and more likely to originate paranoid reactions. Remorse is common in melancholia, but mostly about remote or trifling episodes.

Now as to the fundamental susceptibility to experience or apparently spontaneous affective excess in which the disease consists. We have no knowledge of its essential basis or whether this is in or out of the nervous system, though this is an enormously important question. In considering causation of mental disorder we must always think of four groups of factors: (1) the innate structure of the whole organism and corresponding tendencies; (2) the stage of evolution reached and influence of physiological epochs; (3) mental experiences (recent and remote); (4) physical influences (recent and remote).

I fear we have not progressed far beyond saying that the essence of the manic-depressive diathesis in most cases is an innate and often inherited tendency. At least, we do know that the grouping of cases does not obey the laws of chance but shows family distribution, and that there are families in which the manic-depressive tendency occurs in extraordinarily pure form in numerous members, both in the same generation and in successive ones. These are the well known families where numerous suicides occur and often where exceptional ability is combined with insanity, which is never of deteriorating type. It is a relatively minor point whether such family disposition originates as a spontaneous variation in the germ plasm or, as Myerson suggests, is a heritable modification by injurious action upon the germ plasm of something external (blastophoria).

I wish to discuss briefly the relation of the susceptibility constituting the essence of manic-depressive psychosis to primary disturbances of internal secretion and to infection. Similar mental syndromes often occur with obvious endocrine diseases having bodily symptoms—particularly Graves's disease; they often follow febrile infections, especially influenza. Such neuroses and psychoses, however, are excluded by definition if one limits manic-depressive psychosis to functional conditions.

The attributing of neuroses and psychoses without characteristic bodily changes to primary endocrine disturbances, which has been so popular of late years, is pure speculation. Whether the demonstrable changes in glands are causes, concomitants, or consequences of the nervous lesions is unknown; treatment provides no clear evidence.

Of late years there has been a boom in afebrile focal infection as the cause of neuroses and psychoses. The sites from which it is alleged to be derived are chiefly nasal sinuses, and ear, mouth, teeth, tonsils, stomach, and intestines, the urinary tract, uterus, and vesiculae seminales.

So-called detoxication, including very drastic surgery and vaccine therapy, has had some vogue. The most prominent exponent of this view has been Cotton. He minimizes the effect of heredity and of remote experience, and, though admitting that recent mental stresses may precipitate psychoses, he maintains that "they are due to a combination of many factors, but the most constant one is the intracerebral biochemical cellular disturbances arising from circulating toxins originating in chronic foci of infection situated anywhere throughout the body, associated probably with secondary disturbances of the endocrine system."

Cotton claims astonishing results from detoxication, and a large proportion of these results are in the affective psychoses. It is certain, as Cotton says, that psychoses are generally due to a complex of causes, and probable that latent infection may be one of these in a group of cases, but there is little reliable evidence that it is a large group. Cotton's treatment, repeated by others with control cases, does not reproduce his results. Recovery occurs with the same frequency with and without special treatment directed to focal infection in two series of similar cases. Similar infections are also present in large numbers of people who show no tendency to mental abnormality. Proof that toxæmia is really occurring is almost absent. It proves nothing to show that there is intestinal stasis in melancholia by skiagraphing a bismuth meal. The stasis is more likely to be a symptom than the cause of melancholia. Goodall's review of work done in the examination of blood and cerebro-spinal fluid, of urine and faeces, lends no support to the infective theory of functional psychoses. Almost the only feature suggesting infective origin of manic-depressive psychosis is the leucocytosis sometimes associated with progressive phases.

### Course and Prognosis of Manic-Depressive Psychoses.

Under this head I shall confine myself to principles and omit figures, which would need so much explanation and qualification as to be impossible here. I am aiming at a few hints for individual prognosis rather than statistics.

Many deaths occur which are mainly due to melancholic states; they are apt to figure in certificates under the heading of terminal complications. In some the death is almost inexplicable; the patient is taking an ample supply of food and not extremely restless or sleepless, but weakness and wasting progress. Investigation of these cases is badly needed. Their number is, of course, trivial compared with those of lives saved—a fact to be remembered in these days of abuse of the mental hospitals.

Seen at the beginning of an attack the questions quite reasonably asked by relatives are the following: its probable length; the chance of preliminary intensification; the likelihood of cure or persistent abnormality. In the event of persistent abnormality, what is likely to be the degree of this? Whether abnormality persists or not, what is the probability of further acute symptoms? To all these questions we can only give the vaguest answers. Though we cannot concede that there is any special spontaneous form of syntonie psychosis, yet it is certain that in many cases there is a phasic state of susceptibility to experience the basis of which is as mysterious as the readiness of a plant to respond to conditions in the spring and autumn.

Again, though it is impossible to discriminate groups in virtue of susceptibility to treatment, yet at times the emotional excess, even if started by shock, attains a sort of independence, and is as certain to persist and even get worse for a time despite all treatment as the symptoms of a case of typhoid in the first week. In recurrent manic-depressive attacks the duration of both attacks and intervals is usually quite irregular. Abrupt onset and termination are rare. So far as I have seen, cases in which excitement or depression approaches a possibly certifiable degree and lasts less than two or three months are also rare; possibly more such may get well in nursing homes and observation wards than is suspected. I should be interested to hear the experiences of others. Far more than half the recoveries occur in the first year, and the large majority of the rest in the second year.

In attempting individual prognosis three sets of facts must be considered: details of present symptoms, etiology, and course up to date.

The two elements of the melancholic reaction—the intellectual and conative reduction without disorder, and a fundamental affective disturbance capable of elaboration into grief, misery, or fear—seem the primary response in most mental cases to any noxious influence, whether a situation or a physical stress. Most other reactions are secondary, so that we can say that the major part of psychiatry is the study of morbid unhappiness and how people show it and mask it. Every future is possible in a young person seen for the first time in a manic and still more in a depressive state. If symptoms remain confined to the syntonie type then permanent recovery is more common than with any other type (except perhaps the confusional), and so is complete intermission with recurrence (both results, of course, may occur with any form of reaction). Estimation, therefore, of the degree in which the syntonie is mixed with paranoid and schizoid signs is very important. Such intermixture if absent at first may develop later. Pure chronic mania without any element of these reactions is a rarity; pure chronic melancholia less uncommon. It is necessary to consider the special significance (a) of the different types of emotion—grief, wretchedness, and fear; (b) of various motor accompaniments—stupor, restlessness, resistiveness; (c) of insight, delusions, and hallucinations. These features have relations to other factors, such as age and causation, which more directly affect the prognosis.

Bodily symptoms are often the best indication of coming recovery. Improved appetite and regularity of bowels, sleep, clearing of the complexion, increase of weight, and return of menstruation may be noted even before any increase of activity, and long before any admission of feeling better can be extracted.

In regard to the relation of prognosis to etiology, we recall that neuropathic inheritance decreases the probability that the attack will be a transitory isolated episode. But the chance that recovery and no dementia will follow a given attack is greater when it is known that the family disorder has usually been of the phasic type. This may be a fact of great practical importance. A personal history indicating mere emotional instability has the same prognostic value as similar family history. Abstraction, sullenness, or eccentricities suggest schizoid tendencies; suspicion and conceit, paranoid ones. The prognosis of puerperal psychoses is good, but they are very liable to recur with childbirth. The idea that anything but mild disturbances which start about the menopause are specially likely to clear up with its completion seems to have little foundation.

The prognosis of recurrences even in advanced age is good in the absence of arterio-sclerosis and evidence of dementia. First attacks in the involutional period are apt to be more prolonged, but eventually clear up in two-thirds of cases. Again, excluding arterio-sclerosis, prognosis is ultimately only unfavourable if there are schizoid or paranoid features.

The graver psychoses precipitated by really severe mental stress are apt to be syntonie rather than schizoid. *A priori* one might expect that the resilience of a person thoroughly normal until broken by exceptional disaster would assert itself, and therefore that recovery would be exceptionally frequent in such cases. I have noted a statement to the contrary in Maudsley's *Pathology of Mind*, and there is, of course, an old saying about the effect of storms on oaks and reeds. I believe the chances of the weakling upset by trifles are the better.

It must be admitted that by far the safest recipe for the psychiatric prophet is a judicious use of the probability that what has steadily progressed until now will continue to do so; the outlook is good in proportion as the onset was stormy, bad when it was insidious. The proportion of ultimate recoveries will be much greater among a group of cases seen within one month of onset than in a group seen after six months, and this for natural reasons without regard to treatment. A patient who has recovered once will probably do so again.

### DIAGNOSIS.

Having excluded organic disease, diagnosis includes:

1. Exact estimation of the degree in which all causes interact in production.
2. The problem of the exact proportion in which various reaction types are traceable.
3. Consideration of how far various kinds of syntonie anomaly are present.
4. Determination of practical probabilities—for example, in acute attacks the dangers of exhaustion and injury to self or others, the suitability for voluntary treatment; in quiet phases, fitness for work and likelihood of benefit from this.

For exclusion of organic diseases there are only two requisites—complete examination and a sound knowledge of neurology. Details of mental states are entirely unreliable. There are cases of general paralysis that no one, however expert, can distinguish from neurasthenia or from true mania without a Wassermann test of the cerebro-spinal fluid. Encephalitis is frequently responsible for aimless unemotional restlessness, but very rarely in my experience for true mania. Diagnosis, however, from functional melancholia is often extremely difficult. It should be made only on such grounds as history of a febrile attack with characteristic drowsiness or ocular palsies, or on presence of physical sequelae—most commonly Parkinsonism. Pre-found depression is very common after encephalitis, and many such cases are desperately suicidal; motives are sometimes, though not always, delusional. Parkinsonism may be very difficult to distinguish from the retardation of some types of melancholia. Motor restlessness like that of the senile is common in children after encephalitis, but emotional exaltation of the manic type is a very rare sequel.

The other organic conditions most commonly responsible for syndromes of the manic-depressive type are arterio-sclerosis, alcoholism, endocrine disorders (especially Graves's

disease), and obvious infections such as influenza. These will not be missed if the need to look for them is borne in mind.

#### TREATMENT.

Treatment of mania will naturally differ from that of melancholia. But there is more difference between the management of cases during attacks and exacerbations on the one hand, and in more or less stationary phases on the other.

The essence of an attack or exacerbation is the clinical fact that emotions for the time have lost enduring relation to current experience, and whatever their origin and intensity they have achieved a sort of autonomy. We must recognize that at present the length of such attacks is largely out of control, that treatment must be symptomatic rather than specific, its objects being to safeguard life, relieve distress, and provide the condition in which natural processes will have a fair chance to produce recovery. The situation is quite like that in tuberculosis or typhoid fever. If the attack is sufficiently severe to unfit the patient for ordinary duties, treatment at home is probably inadvisable. Although in attacks all active psychotherapy, especially analysis of any kind, is merely harmful, yet the loss of relation between current experience and emotion is never absolute; temporary effects are possible by separation from worries and distressing associations, reassurance, kindness, and firmness. The essential combination of these, and especially the last, is rarely obtainable at home. Apart from custom, it would hardly ever be necessary in the first instance for cases of manic-depressive type, whatever their severity, to be treated under a detention order. Both the manic and melancholic, however boisterous or suicidal, usually recognize their need of treatment. They may become intolerant of treatment or intolerable to other voluntary cases, but the practice of certification which has prevailed hitherto results on the one hand from a legal tradition which happily is now nearing death, and on the other from the lack of any place where poor cases can go for treatment apart from the unwilling and chronic.

Specific treatments designed to cut short attacks are many, but their effects unproven. The largest claims have been made for detoxication—that is, removal or disinfection of the foci already mentioned, together with vaccine therapy. Such measures should doubtless be adopted where any obvious physical indications exist, but rarely for mental symptoms in the absence of these, and always with due regard to risks. I have seen a large number of acute mental attacks and exacerbations clearly following extensive dental extraction; it is often difficult to decide in particular cases whether emotional stress or sudden toxæmia is the cause.

The effect of malaria in general paralysis and the way in which intercurrent disease sometimes aborts manic-depressive attacks has led to induction of artificial pyrexia in the latter with various substances. So far results are not definite, but I think the method might be worth further trial, especially in melancholics tending to become chronic. The results of intensive thyroid treatment have been disappointing in my experience.

In the main, treatment of attacks is hygienic. A patient with serious emotional disturbance should be kept in bed as in the case of a feverish tuberculous patient; open air and sunlight are nearly as important in manic-depressive psychosis, and massage is a useful substitute for exercise.

Feeding is the second main essential, and the supply of all vitamins should be adequate. Patients must take sufficient food, and when they are losing weight tube feeding should not be delayed even if only needed as a supplement. It renders possible gastric lavage, which is useful in many cases with atonic dyspepsia, and also the administration of aperients and sedatives without a struggle. Sleep by night and cessation of motor restlessness by day must be obtained. As to hypnotics, I believe, with Sir Maurice Craig, that we take too seriously the danger of habit formation, and too lightly the damage wrought by insomnia. Some success has been claimed for the attempt to cut short manic-depressive phases by induction of twilight sleep for a week with somnifen. I have no experience of its use quite early in an attack; later

I have seen it fail a good many times. Use of sedatives as "chemical restraint" during the day is an unfortunate necessity. It is certain that in some cases they are better for the patient than incessant restlessness; their use in practice cannot be avoided for the sake of other patients. If the interests of the latter and of the staff are not allowed to outweigh those of the patient there is no abuse. Most experienced persons would admit that, subject to the same proviso, there are cases where seclusion and even mechanical restraint would be preferable, but in the case of the latter at least the risk of abuse is so great that its practical abolition is best on the whole. Hyoscine has achieved a quite undeserved ill fame; it seems to me indispensable in many cases. Sulphonal and similar drugs, which have been described as specific for mania, seem to me far the worst of the sedatives, to be used only with every precaution to avoid accumulation and avoided if possible in recent cases. They may be the only drugs that will quiet the intolerable chronic maniac, but of their deteriorating effect in some cases there can be no doubt. Prolonged baths are a useful adjunct in some cases, both to procure sleep and check motor restlessness. Often they need using in conjunction with a preliminary sedative, and will then reduce the use of drugs.

Prevention of injury to self and others is the last point in connexion with treatment of the acute attack. We are losing faith in mechanical precautions and in everything but knowledge of patients and observation. Even this should be unostentatious; the excellent principle of "safety first" can be overworked. Two good rules are to discredit the maxim that those who talk of suicide never commit it, and to remember that most suicides are surprises, often by the convalescent.

I can only just touch upon the question of treatment in those degrees of manic-depressive psychosis (in the broad sense) which are susceptible to psychotherapy. I disbelieve in all theories which single out special patients within this wide group as permanently fitted or unfitted for such treatment. Most are suitable at some time, some never pass the limit which disqualifies them. In tuberculosis it is not different varieties of the disease but varying degrees of activity that necessitate treatment by rest or exercise; the position is similar in emotional disturbances, but at present the indications are more obscure.

Practical treatment habitually ignores theoretical distinctions between suggestion, persuasion, and analysis, and utilizes a compound in which they are inextricably combined. Tracing the devious origin of symptoms and presenting them in a new light for review is often helpful, but some have exaggerated the degree to which repressed complexes are primarily responsible and benefit follows mere elucidation, while others overestimate the extent to which any analysis, however prolonged, achieves lasting reconstruction of temperament. Great practical benefits are obtainable by psychotherapy in emotional disturbances, but they generally seem to depend on getting the confidence of the patient and using this to influence super-added hysterical symptoms and various tendencies to shirk difficulties which the essential temperament multiplies and magnifies.

I hope I shall not be dubbed pessimistic if I express some doubt of the ability of psychotherapy to cure radically, in a large proportion of these cases, the lasting tendency to undue emotion of some type and to phases of reduced efficiency. There is quite a proportion of cases in which one should insist that minor attacks of depression and anxiety must be courageously ignored by some patients, as physical pain by others, or prevented from influencing conduct. The most spectacular effects in psychotherapy are of course achieved by those who believe in their powers to effect radical cures. It is doubtful whether equal good is not done in the long run by patient people who realize that some of these depressives are permanently inadequate in one way as the feeble-minded in another, and who recognize that many need sheltered conditions with occasional guidance, support, and control. Treatment often consists of the intelligent provision of these at the right time, and fortunately the results are at least equal to those achieved in any chronic disease.

# MANIC-DEPRESSIVE PSYCHOSIS.

## DISCUSSION.

The President said that in choosing manic-depressive psychosis for discussion by this Section it was felt that the time was ripe for the subject to be reviewed by an authority such as Dr. Mapother. Those present had listened to a paper full of instruction, information, and suggestion, and the additional merit of being controversial, and perhaps even provocative. Dr. Buzzard believed that this psychosis in its mild and moderate forms was a very common, if not the commonest, mental disorder; it was rarely recognized, except by experts; but its recognition was a matter of great practical importance in relation to prognosis and treatment. It was as common as migraine, which it resembled in some etiological particulars. As in the case of migraine, the hereditary factor loomed large. Manic-depressive psychosis was rarely met with except in families with definite psychopathic taint. Its manifestations varied greatly in their degree of severity and in their periodicity, but made their appearance chiefly during the years of active sexual life, with a tendency to exaggeration towards its close. Dr. Buzzard disagreed with Dr. Mapother's statement that little was known about the exciting causes of its attacks, although a large percentage of patients recovered. Dr. Buzzard had achieved a persistent acceptance even among the large majority who rejected Freud's views as to its causation, and that there seemed to be no particular objection to isolating it if it was regarded as merely one of the numerous subdivisions of depression, loss of energy, decision, interest, and concentration, and presented no signs of organic disease, the question which arose in a large majority of cases was the discrimination between a manic-depressive psychosis and an anxiety neurosis, although that the distinction between these two conditions, in regard to prognosis and treatment, as well as in the interests of academic accuracy. If he came to the conclusion that the patient was a manic-depressive, but at an uncertain date, sometimes difficult, was of fundamental importance in his recovery as more or less assured, but at an uncertain date. He was concerned that the patient should be safeguarded against possible suicidal tendencies, that he should have constant sympathetic care and encouragement, and that he should be protected from any form of analysis. Help in regard to sleep, feeding, and environment might be necessary, but of direct curative measures he admitted complete ignorance. In short, he recognized that the patient was the victim of a disorder in which physical and mental symptoms were closely associated, and perhaps interdependent, and that he required all that his doctor could give him of time, patience, and assistance until Nature restored him to health. The doctor who was in charge of the patient when he recovered, and the treatment prescribed, would gain the credit of a cure—a credit which would all probability fail to survive the next attack. If, on the other hand, Dr. Buzzard came to the conclusion that the patient was suffering from an anxiety neurosis, he regarded his recovery and its date as dependent on the success of any measures directed towards its removal. He had little fear of suicide, and no dread of skilful analysis. In other words, he realized that the condition was a mental disorder which could be directly attacked, and that the disappearance of any physical symptoms of which the patient complained would coincide with the restoration of his peace of mind.

These alternative conclusions might be fallacious in conception and reached on inadequate grounds, but if they were a guide to prognosis and treatment, how could they be reconciled as merely one of the numerous subdivisions of the manic-depressive group?

The question of diagnosis was sometimes easy, sometimes very difficult. In the first place, a very careful and detailed history was as essential here as it was in the diagnosis of any disorder, physical or mental. In the second place, he would stress the loss of interest in all pursuits and of affection for all persons exhibited by the manic-depressive on the psychological side and the change in his

appearance, colour, and smell on the physical side. Disturbances of sleep were less profound and less difficult to overcome in the manic-depressive than in the patient suffering from anxiety neurosis.

Last, but not least, it was always possible to find a cause for an anxiety neurosis, while it was often impossible to discover an adequate reason for a depressive phase in a manic-depressive.

Dr. Buzzard hoped that efforts would be made to popularize what knowledge they possessed about a very common malady, and one which was of as much interest and importance to the general practitioner as to the consultant in psychiatry or neurology. He had already contended that the name of this psychosis was a serious bar to its general recognition, and in conclusion he felt he could hardly do better than commend to the members of the Section as a holiday task the discovery of an alternative and less objectionable title than that of manic-depressive psychosis.

Dr. T. A. Ross (Penshurst) joined issue with that part of Dr. Mapother's paper in which he identified the psychoses with the psychoses. For Dr. Mapother to attempt to distinguish between them was a useless exercise, although he admitted that the attempt to do so had grown out of practical differences, particularly as regards certification and asylum treatment. Dr. Ross confessed that if he were suffering from a condition which might or might not at some future time lead to detention and loss of liberty he would be glad to have a physician who would engage in the useless exercise mentioned. He had long wondered how Dr. Mapother had been led to the conclusions he held, and he thought that to-day he had solved this problem. Dr. Mapother had said that details of mental states were entirely unreliable; the investigation of them was, therefore, to his mind a useless exercise. Dr. Ross thought that if Dr. Mapother would carefully study mental states he would find that they would lead him to perceive fundamental differences between the psychoses and psychoneuroses. It was rash to call any clinical examination a useless exercise. When the speaker was a student the plantar reflex used to be examined to see whether it was present or absent. It was then a perfectly useless exercise for most people, but one man at any rate had since made something of it.

Dr. Ross wished to put forward some proof that their study did as a matter of fact lead to something demonstrable, something of value. He proposed to take as a criterion the fact of certification. He proposed to take as a criterion the fact of certification. At once it would be said that certification was a legal and not a medical question: that was only partly true. Certification was an admission that the patient in question was so far removed from deprivation of liberty that he could not be dealt with without deprivation of liberty. Certification depended also on social status; it was not fair to compare the numbers of certifications of the poor with those of the rich; the poor required certification for less illness than the rich. But the figures he would put forward were all drawn from substantially one class—those who were not rich among them. Since the Cassel Hospital opened they had 66 patients who were definitely labelled by them as manic-depressives. They were not sent as such. Most of them were labelled neurasthenics: none were then certified. The diagnosis from a psychoneurosis was made on an examination of the mental state. Of these patients 12 had since been certified, and 3 others who unfortunately were not certified had committed suicide. During the same period 355 patients definitely diagnosed at the Cassel Hospital as suffering from one or other form of psychoneurosis were admitted; of these, 3 had since been certified. Two of these, had Dr. Ross followed his own rules, he would not have put him into that group. But if not was warned that he was making a mistake—that the patient was really a manic-depressive. In one case he ptom which certainly put him into that group. But if not allowed to transfer them, three errors of diagnosis out of 355 patients—less than 1 per cent.—were insignificant. Even if it was impossible to be sure in less than 1 per cent., when it could be shown that over 20 per cent. of those diagnosed as manic-depressives would need asylum treatment, the "useless exercise" seemed worth trying.

As regards the important points in the diagnosis. He would begin with a mental symptom, which Dr. Mapother

said was a common one—namely, remorse. He thought it might be said that this was a very great diagnostic symptom. No patient suffering from a psychoneurosis complained of remorse. If a patient suffered from this he was certainly in the depressive group, and one could not promise him immunity from loss of liberty. It should be understood that he was talking of a patient before he had had any sort of analysis; an analysis might reveal something which called for remorse. But while the psychotic-depressive on the whole tended to blame himself for his state, the psychoneurotic always blamed someone else, if, indeed, he was not praising himself in showing that his illness had been due to overwork and self-sacrifice. Here, then, a very striking difference was perceived in mental reaction between the two groups. This question of overwork led to a second point in diagnosis, for although the psychoneurotic often spoke of overwork, a critical estimation of what was actually done did not make the physician feel that the amount accomplished had really been great; the psychoneurotic did not do anything so foolish as to overwork himself at any time of his life. But a well authenticated history of overwork was often obtained in the case of a manic-depressive. He would not care to assert that the overwork was the cause of the breakdown; it might equally be true that it was a symptom of a mild manic phase when the patient thought that he was invulnerable. This led them to consider history a little more, and when this was done it would be found that the story of the intervals between the attacks was different in the two conditions: the psychoneurotic was never in quite good health; when he was well he was "highly strung" or dyspeptic, and was often consulting a doctor: the depressive when he was well was really quite well. He did not think that the opener had emphasized sufficiently the importance of history; in the diagnosis from organic disease Dr. Mapother said there were only two requisites—namely, complete examination and a sound knowledge of neurology. Dr. Ross thought history would be found more important even than examination, and the fact that Dr. Mapother emphasized neurology, and not cardiology, gastrology, proctology, and all the other ologies of the body, made the speaker suspect that it was only a very small section of the psychoneurotic group that found its way to the Maudsley Hospital. He thought that if Dr. Mapother had seen a number of people whom he could not be sure about—for example, whether they were suffering from a psychoneurosis or from cancer of the stomach—he would be more willing to admit that there was really a difference between the former and the psychoses. There was a great difference in reaction to mental environment between the two conditions. If the psychoneurotic was in an environment where he was perfectly happy, he was better for the time being. This environment might be provided in many ways: an attentive doctor, an interesting treatment, a holiday with congenial companions might provide it. Such things usually had no effect on the psychotic, and if they had, it was never in so striking a manner. Equally, displeasure at once cast the psychoneurotic down, and affected the psychotic very little. In nothing was this shown better than when an attempt was made to give aesthetic pleasure. The psychoneurotic who looked on a beautiful garden obtained as much pleasure out of it as anyone else; the psychotic said he could see it was beautiful, but he could not feel it.

These, then, were some important differences; and if he had shown that the exercises were not wholly useless, had they any value in treatment? His answer was that appropriate treatment could not be undertaken in the absence of such a diagnosis. The psychoneurotic was capable of enormous improvement if his mental orientation was altered, and the physician could alter it by the various forms of psychotherapy in the large proportion of cases. The manic-depressive psychosis was a disease which ran a course; the physician had little power to make any striking alteration in orientation. He could take care of his patient, and thus indirectly could hasten, perhaps, recovery, but active therapy was out of the question. Dr. Ross therefore absolutely controverted Dr. Mapother's view that the two states showed no difference in reaction to treatment.

Dr. R. D. GILLESPIE (London) considered that a definition of "manic-depressive psychosis" was certainly desirable, since there had been an inclination to give the term an application so wide that its meaning had become vague and its value doubtful. Before dealing with Dr. Mapother's definition, he wished to draw attention to the opener's preliminary remark, that the primary problem was what meaning should be attached to the term "manic-depressive psychosis," and that there was no constant and specific cause and no physical modification recognizable. The failure to mention clinical criteria Dr. Gillespie would have regarded as an accident, were it not for the remark later in the paper that details of mental states were utterly unreliable. This tendency, more or less unconscious, to depreciate clinical differentiation gave the key to Dr. Mapother's subsequent surprising classification of all psychoneuroses as a subdivision of the manic-depressive psychosis. In his definition the depressive phase was characterized as showing a "morbid dissatisfaction with the self or circumstances." That Dr. Mapother did not really consider this to be a good characterization was shown by his subsequent remark that in a surprising number of even the severest cases of melancholia there was a "formless" sense of one of the types of distress mentioned. This was precisely the point. The feeling that was called depressive in these patients was often "formless"—there might be neither "morbid dissatisfaction" nor "dissatisfaction with the self or circumstances," but only something vague and very unpleasant in tone. From this arose the difficulty that these patients so frequently had in expressing their condition to the physician. In the definition of the manic phase "misdirection" of activity should surely have been "continuous change of direction"; otherwise the definition could have applied almost to a full-blown paranoia. The truth was that the manic-depressive psychosis was essentially a clinical conception, and that an attempt to define something that had been differentiated on purely clinical grounds in terms of academic psychology after McDougall was likely to fail. It seemed probable that cases beginning as "pure manic-depressive psychoses" and ending as dementia praecox became very much fewer as more attention was paid to clinical differentiation. That was not the only type of dementia which occurred. Kraepelin himself recognized a tendency to dementia, not schizophrenic in nature, after repeated attacks. That there was a "continuous graded series" between the neuroses (or rather the psychoneuroses) and the manic-depressive psychoses was not a conviction that was generally held. If the question of the interrelationships of the psychoneuroses and manic-depressive disorders was placed on a broad biological basis very great differences were found, according to members of Kraepelin's own school, such as Jango and Cimbal. (1) The heredity of manic-depressive disorders was a similar one; while in the heredity of psychoneurotics occurred schizophrenia, epilepsy, and psychopathic states. (2) The type of pre-morbid personality was different in the two groups. (3) The physical types, if Kretschmer's work was accepted, were different in the two groups. The value of Kretschmer's work on physique and character, although widely confirmed on the Continent, was, of course, still *sub judice*. Certainly among sixty successive psychoneurotics recently seen by the speaker there was not one of the classical "pyknic" type. (4) The somatic morbidity was different in the anamnesis of the two groups. (5) The physical disturbances actually accompanying the mental conditions differed in kind as well as in quantity in one group as compared with the other.

That "obsessions were common in melancholics" was an original observation which he would have liked to see expanded. By "anxiety neurosis" it was presumably intended to designate also "anxiety hysteria," since here Dr. Mapother referred explicitly to Freud. When it was said that "anxiety neurosis" merged by a continuous series of gradations into agitated melancholia, presumably not melancholia agitata, which might have no anxiety, but anxiety melancholia was intended. Here it seemed to the speaker, on the contrary, that something entirely discontinuous was introduced—namely, the melancholia. There were numerous clinical differences between anxiety states

# SECTION OF ANAESTHETICS.

in general and melancholia; for example, the former had frequently a brief episodic appearance; and they had often an immediate and complete dependence on external circumstances in a way unknown in "true melancholics." Who had heard of a melancholic of the manic-depressive type who was well and at ease while he sat in the garden, but was plunged in misery when he returned to the drawing-room? Dr. Gillespie had at the present time a patient with such an anxiety state.

Dr. Mapother had rightly described "sorrowful memories in melancholics"; he thus touched unwittingly on another distinction from psychoneurotics. In the latter it was precisely that the troublesome ideas were not sorrowful, and the problem before the physician was to discover why ideas apparently colourless in themselves should be so distressing. That the enduring character of the hysteric was the "persistent analogue" of the mixed manic-depressive was a statement that must also be challenged in the interest of clearness. If true manic and melancholic ailments were common in hysterics it would be expected to find both of two things: First, that hysteria was common in the anamnesis of manic-depressives. The general impression was that it was not. In the last twenty-one depressives he had treated and investigated extensively, only two had any symptoms that appeared hysterical, and one of these was a very problematical case. Secondly, they would expect to find a manic-depressive history commonly in hysteria; in his last thirty cases of hysteria Dr. Gillespie had not found one such.

The "useless exercise of making a diagnosis between functional neuroses and psychoses" would not be saved by the discovery *post mortem* of a patho-physiological basis for each of them. Further, the distinction between neuroses and psychoses rested not upon the problem of certification so much as upon the problem of treatment. The treatment that was suitable for a manic-depressive was fatal to a psychoneurotic, as Dr. Gillespie knew to his cost. He had not tried the converse process—the application of the methods for psychoneurotics to psychotics; but he had met the results of such an application and they had been among the most seriously ill patients he had seen. Blood pressure showed little or no correlation with mood, and very little with behaviour in mental patients. The changes in the cortex in dementia praecox described by the late Sir Frederick Mott awaited confirmation. The best controlled work on the subject (that of Dunlap) had in fact shown no cortical changes.

The task of psychopathology at present was not so much the discovery of a physical basis—that was not psychopathology, and smacked of the pseudo-physiologizing of the latter half of the last century which Meyer had well designated "brain-mythology"—but the unravelling of the meaning and origin of mental symptoms as such. That there was a "phasic state of susceptibility" in manic-depressive illnesses seemed not by any means proven. Statistics from the New York State hospitals showed that of about 12,000 manic-depressive cases, only 50 per cent. had a second attack, and only 25 per cent. had a third.

It was to be regretted that Dr. Mapother had made no mention of MacCurdy's work on the manic-depressive psychosis. Whether MacCurdy's views were accepted or not, his case material was clinically the best that had been published in this country on this topic. His work did much to upset that might be called the "psychiatrist's fallacy"—that thought always followed emotion. Emotion probably more often followed thought. The poets recognized this, if many psychiatrists did not—"My heart leaps up when I behold a rainbow in the sky." It seemed to the speaker that it might be more helpful to speak of the speaker that it might be more helpful to speak of "primarily affective disorders; (2) reactive episodes in follows: (1) manic-depressive disorders; (3) affective episodes in disorders (depression usually); (4) psychoneurotic mood-disorders; and (5) miscellaneous group. In this or some similar way a heterogeneous mass of material could be subdivided, the conception of the manic-depressive psychosis clarified, and all of the manifestly affective reaction types better understood.

Dr. R. H. Cole (London) believed that everyone was liable to manic-depressive psychosis was merely an exaggeration of this state. It was doubtful, however, if sufficient evidence existed for saying that a psychoneurosis could become a definite psychosis.

Dr. Mapother, in reply, said that discussion had centred almost entirely around the relation between the neuroses and psychoses. There had been some distortion of the views expressed in the paper, doubtless due to lack of time to consider it. Dr. Ross had suggested that it made light of the need to estimate the risk of suicide. On the contrary, this need was specially mentioned under diagnosis. It would be best met by labelling the words that the speakers had detached from their setting the words that details of the mental state were unreliable as a basis for exclusion of organic disease and had ascribed to him the general view that investigation of such details was unnecessary in dealing with neuroses and psychoses. The real fact was that he took a wider view of the usefulness of such investigation than those who believed in two distinguishable syndromes—one due to mental causes and capable of mental cure, the other with a course quite independent of such causes and treatment. As Dr. Ross had raised the question of personal experience, he might say that he spent most of three years in various hospitals dealing with the war neuroses, and for the past three had been connected with the only hospital in this country where it was possible to get simultaneous experience of both extremes in mental disorder and of the intermediate cases that were the crux of this question. He could only express surprise when Dr. Gillespie and Dr. Gordon doubted the occurrence of cases that were at first indistinguishable from manic-depressive psychosis and ended as dementia praecox. He thought most of those with considerable experience as medical officers of a mental hospital would have seen such cases. Most of the speakers seemed still to adhere to the limited idea of manic-depressive psychosis as occurring entirely in clear-cut spontaneous phases. Dr. Gillespie's remarks regarding treatment probably ignored the fact that what he found so disastrous was only recommended for phases where the patient was inaccessible to psychotherapy. He did not question the ability of Dr. Ross to foretell correctly the chances of suicide and certification in a large proportion of cases, especially if they were mostly chronic. Whatever the exact form of symptoms there was a tendency in some attacks to occurrence in acute attacks, in others to minor attacks or chronically; after years, of course, probabilities could be estimated. He thought that Dr. Ross consciously or unconsciously considered known course as well as form in making a diagnosis. The test would be his ability to forecast the course from the form just after the first beginnings of symptoms in the patient.

## SECTION OF ANAESTHETICS. SAMUEL JOHNSTON, M.D., President.

### DISCUSSION ON ANAESTHESIA IN RELATION TO CARDIO- VASCULAR AFFECTIONS.

#### OPENING PAPER

BY  
FREDERICK W. PRICE, M.D., F.R.S.Ed.,  
Physician, National Hospital for Diseases of the Heart;  
Consulting Physician, Royal Northern Hospital, London.

In the course of my professional work I am sometimes asked to give an opinion regarding the risk of inducing anaesthesia, for the purpose of an operation, in those who are the subjects of some cardio-vascular affection, and also, in a certain proportion of these, which is the safest anaesthetic to administer. I frankly confess that this is one of the responsibilities which I least like undertaking. The decision is often one attended with great difficulty, and in this connexion, at the outset of my remarks, I desire to

express most sincerely and warmly my great admiration for the courage and ability with which the anaesthetist faces and discharges his responsible and difficult task; and furthermore, I should like to bear my grateful testimony to much that I have learned from him, and—may I add?—from the surgeon also.

I feel considerable diffidence in addressing an audience of experts, such as this is, on this important subject. I can even understand it being stated that the cardiologist is seldom, if ever, able to render much practical help, and yet I venture to hope that it is possible for him to furnish something of value to the common stock of useful information on the subject.

As far as my experience and observation go, speaking generally—that is, taking cases as a whole—given adequate knowledge and skill and care, the subjects of cardio-vascular affections stand the induction of anaesthesia surprisingly well. Indeed, it has even been stated that if a person is able to undergo an operation it will not be impossible for him to stand an anaesthetic. It may be added that if a fatality does occur during the induction of anaesthesia in the subject of a cardio-vascular affection it may have been due to the choice of the wrong anaesthetic or the manner in which the anaesthetic was given. But, unfortunately, painful surprises do sometimes occur in the experience of even the most skilled anaesthetists. As I shall show you later, these are usually cases of unrecognized chronic myocardial disease. How to avoid so unfortunate an event is the main purpose of my remarks this morning.

Reduced to simple terms, an operation means, in essence, an added piece of work—an added load—of varying degree, depending upon the nature and duration of the operation, to an impaired heart, or an impairment of some other part of the cardio-vascular system. The fundamental question which has to be decided is whether the various parts of the cardio-vascular system can stand this. If this is doubtful it is a case of comparing this risk with the degree of urgency of the operation proposed. Questions of diagnosis, prognosis, and, it may be, treatment, are involved; and prognosis depends largely, if not almost entirely, upon accurate diagnosis.

It is generally recognized that within recent years there has been a great advance in our knowledge of cardiac disorders, and that this advance has been of vital importance with regard to diagnosis, prognosis, and treatment. I would plead the great advantage of a closer acquaintance, of a practical kind, on your part, with this advance. It is true that this progress has been mainly the result of the employment of the clinical polygraph and the electro-cardiograph. Let me, however, encourage you by pointing out that, the work of elucidation having been accomplished, it is not now necessary to employ either the clinical polygraph or the electro-cardiograph in the great majority of cases, the use of a sphygmograph being sufficient, and in a large proportion palpation and auscultation are all that is necessary.

It is obviously impossible, in the time at my disposal, to deal with the whole subject of the cardio-vascular system from the point of view of the induction of anaesthesia. I shall content myself by making some practical observations with regard to some of the more important points.

Passing to the clinical examination of the heart, I would emphasize that the rate and rhythm of the heart should always be determined at the cardiac apex, either by palpation or auscultation, preferably the latter—for two reasons: (1) the rate of the radial pulse does not necessarily represent the ventricular rate; and (2) in order to determine the type of irregularity, which is of great practical importance.

#### *Rate of the Heart.*

It should be remembered that the normal cardiac rate has a considerable range of variation in perfectly healthy individuals. Also I need scarcely remind you that tachycardia may be due to the excitement incidental to a medical examination. May I point out that by the term "bradycardia" is meant infrequent action of the heart, and that it must be distinguished from infrequency of the pulse rate at the wrist? Bradycardia also may be physiological,

especially in males. It is difficult, therefore, to decide when tachycardia or bradycardia in an individual is pathological. In both cases a record of the past history is of value. It is scarcely necessary to observe that there are many causes of the pathological form of tachycardia and bradycardia other than the various kinds of heart disease. The increase in the cardiac rate induced by physical exertion varies in healthy individuals. It is, therefore, difficult here also to determine whether an increase in rate is pathological. In this connexion, the presence or otherwise of accompanying subjective symptoms of cardiac distress is of fundamental importance. Other causes of an abnormal increase of the cardiac rate on physical exertion than cardiac disease proper, such as atony of the wall of the heart muscle the result of lack of physical exercise, and poisoning of the heart without structural damage, should not be forgotten. The time which may elapse before the cardiac rate returns to its former level after physical exertion is of greater significance than the degree of increase induced by the exertion.

#### *Irregular Action of the Heart.*

Irregular action of the heart is of great practical importance in regard to the subject-matter of our discussion. I mean irregular action in itself—that is, without reference to the cause or the condition with which it may be associated—and my remarks shall be used in this sense only. Formerly, this subject was a source of great perplexity and difficulty to the clinician. It was known that irregular action of the heart in itself might, on the one hand, be of even serious significance, or, on the other hand, that it might be of no practical importance at all. It was not possible, however, to determine the significance of the irregularity in any given case. We are now able to classify almost every case of irregular action of the heart into types, and we know what each type signifies; and, most fortunately, it is possible to determine the type by palpation and auscultation alone in the great majority of cases, and, in case of doubt, by the use of a sphygmograph in the vast majority of cases.

All cases of cardiac irregularity, apart from comparatively rare exceptions, fall into one of six groups: (1) What is called sinus irregularity; (2) irregularity due to premature contraction or extra-systole; (3) irregularity due to heart-block; (4) irregularity due to pulsus alternans; (5) irregularity due to auricular fibrillation; and (6) irregularity due to auricular flutter.

In sinus irregularity there is a variation in the length of the diastolic period of the cardiac cycle, while the systolic period remains constant, and this can be detected by the stethoscope. If a tracing of the radial artery be taken, the intervals between the beats will be found to vary, but the actual variations are not numerous, while the pulse beats are of equal, or nearly equal, size. When irregularity of the cardiac action is found to be definitely related to respiration it is in all probability of the sinus type.

By extra-systole is meant a premature contraction of the auricle, or of the ventricle, or of both chambers together, while the fundamental or sinus rhythm is otherwise maintained in most cases. Usually the extra-systole is followed by a long pause—the compensatory pause. On auscultation, in the vast majority of cases, two heart sounds are synchronous with each cardiac cycle; sometimes only the first sound; very rarely is there an absence of both sounds. Extra-systoles may appear at long or at frequent irregular intervals, or regularly after each normal beat, or after every second, or third, or more, normal beats, or in paroxysms. An extra-systole may be so feeble that no wave is felt at the wrist, so that there is simply an abnormally long pause, resulting in an "intermittent" pulse. If a single extra-systole, with its succeeding compensatory pause, occurs after every two normal beats, the pulse beats occur in threes, the condition being known as pulsus trigeminus; but if the premature contraction is so feeble that no wave reaches the wrist, the pulse beats are paired (pulsus bigeminus). If an extra-systole occurs regularly after each normal beat and the extra-systole fails to reach the wrist on each occasion, the rate of the arterial pulse is halved.

In the great majority of cases a correct diagnosis of the existence of extra-systoles can be made simply by palpation and auscultation, especially the latter. The normal rhythm of the heart is disturbed by the occurrence of a premature beat, followed by an abnormally long pause. The auscultatory signs are of great diagnostic value. I shall refer to the differential diagnosis between extra-systoles and partial heart-block in a moment. It is sometimes very difficult, if not impossible, to distinguish by palpation and auscultation alone between extra-systoles occurring frequently and at irregular intervals, especially if of auricular origin, and auricular fibrillation; but in such cases a sphygmographic tracing is almost invariably sufficient.

There are three degrees of auriculo-ventricular block:

(a) There may be merely a prolongation of the interval which separates the commencement of the contraction of the auricle and that of the ventricle, each stimulus of the auricle reaching the ventricle, which duly responds. (b) The stimulus does not always reach the ventricle—in other words, the ventricle does not always respond to the stimulus from the auricle. (c) A condition in which no impulses reach the ventricle from the auricle, so that the auricle and ventricle beat independently of each other. The first two of these are referred to as "partial heart-block," and the third as "complete heart-block." The first grade can only be recognized by means of the polygraph or the electro-cardiograph. The second degree of heart-block may give rise to intermission of the pulse, pulsus bigeminus, pulsus trigeminus, and infrequency, including halving, of the pulse rate. Extra-systoles or partial heart-block account for the vast majority of such cases.

The differential diagnosis between these conditions, due on the one hand to extra-systoles and on the other to partial heart-block, can be readily made, as a rule, by means of palpation and auscultation. In the former case a premature beat can be detected at the apex-beat, and on auscultation one or two heart sounds will, in the great majority of cases, be audible during the early part of the pause, because the ventricle has contracted; whereas, in the case of partial heart-block, there will be an absence of an apex-thrust and of heart sounds during the pause, because the ventricle has failed to contract. In complete heart-block the pulse rate is usually not more than 36, though some cases have been recorded in which the rate has been even up to 60 or more a minute. It is sometimes difficult to distinguish between partial and complete heart-block without the aid of the polygraph or electro-cardiograph. Most cases with a ventricular rate of 36 or under, however, are cases of complete heart-block. When bradycardia is due to complete heart-block the ventricular rate is not increased by posture, physical exertion, emotion, or pyrexia.

A lesion of either the right or left main branch of the auriculo-ventricular bundle, and what is called intra-ventricular block (a condition in which there is abnormal conductivity of the subendothelial arborizations of the auriculo-ventricular bundle), can be diagnosed by the electro-cardiograph alone.

By pulsus alternans is meant a condition of the pulse in which, while the rhythm is perfectly regular, a large beat and a small beat alternate. In the vast majority of cases it is necessary to take a tracing of the radial artery in order to recognize the condition. It is of the utmost practical importance that the variety of irregular action of the heart indicative of auricular fibrillation should be recognized. This type of irregularity presents the following features: (a) It is continuous. (b) The irregularity is complete; the rhythm is irregularly irregular. In a sphygmogram it will be found that two beats of the same length or amplitude rarely follow each other. There is often no relation also between the length of a pause and the amplitude of the beat which follows it—that is, a short pause may be followed by a strong beat, and a long pause by a weak beat. We may be reasonably certain of the existence of auricular fibrillation from the mere presence of complete irregularity of the pulse. It is possible to determine complete irregularity of the pulse in a large proportion of cases by palpation and auscultation alone.

When, however, the ventricular rate is slow, or very rapid, the irregularity may be only slight, and it may be necessary to adopt careful measurements of the sphygmogram to detect it. It is necessary to exclude irregular action of the heart due to extra-systoles or to auricular flutter. In most cases of auricular flutter the rhythm of the arterial pulse is regular. Not infrequently, however, there is irregularity of the pulse rhythm, it may be even markedly so, and in some of these cases a sphygmogram may resemble that of auricular fibrillation. In this connexion, if a sphygmogram from a case of auricular flutter be carefully studied, it will be found that even if the ventricular rhythm is markedly irregular the pulse beats measure out into groups of equal length, whereas this is never the case in auricular fibrillation.

#### Paroxysmal Tachycardia.

By paroxysmal tachycardia is meant a condition in which a marked acceleration of the cardiac rate occurs, which commences suddenly and abruptly and without apparent cause, lasts for a varying period, ceases suddenly and abruptly, and is due to an abnormal rhythm—the stimulus for cardiac contraction, instead of arising at the junction of the great veins with the auricle, having its origin at an abnormal point. A diagnosis of paroxysmal tachycardia is usually possible without having resort to instrumental methods. Thus: (1) The suddenness and abruptness of the onset and termination of the tachycardia is a characteristic feature—the maximum rate is attained within a few seconds, and the return of the cardiac rate to what it was prior to the attack occurs equally quickly; whereas in tachycardia associated with the normal rhythm the onset and termination are gradual. (2) A persistent rate of over 160 is almost invariably due to an abnormal rhythm. (3) With the exception of those cases due to transient attacks of auricular fibrillation, the cardiac rate is not influenced by posture, physical exertion, emotion, pressure upon the vagus, or pyrexia, as is the case in tachycardia associated with the normal rhythm.

What is the prognostic significance of the various types of irregular action of the heart in themselves—in other words, what practical bearing do they have upon the subject-matter of our discussion? Sinus irregularity may be entirely disregarded. The question of extra-systoles is of great practical importance; they constitute one of the most frequent causes of irregular action of the heart, and may give rise to very disagreeable symptoms. There is considerable diversity of opinion as to their prognostic significance. Further experience has not led me to change the opinion I expressed in 1911—namely, that there is so far no evidence for supposing that extra-systoles are either indicative of an impaired heart or that they add to the gravity of any existing morbid condition; so that with regard to the subject-matter of our discussion they may be disregarded. The occurrence of partial heart-block during the course of an acute infective disease is a sign, and may be the only sign, of myocardial involvement. Persistent heart-block of mild degree is also indicative of myocardial damage. The prognosis of bundle-branch block is usually very unfavourable. That of intraventricular block is almost always of grave import. From the point of view of the anaesthetist there are two kinds of pulsus alternans—namely, one in which the condition is associated with a severe grade of tachycardia, and the other in which it is not. In the former event it does not appear to have any serious significance in itself. In the latter, however, it is an indication of extreme exhaustion of the heart muscle, and should be regarded as an imperative call on the part of the heart for rest—complete and prolonged. Auricular fibrillation is in the vast majority of cases indicative of some myocardial change. Put briefly, the prognosis depends upon the ventricular rate, the degree of any existing cardiac failure, and the response to digitalis therapy. I shall refer to the last point later. With regard to the risk of inducing anaesthesia in an individual who is the subject of paroxysmal tachycardia, this depends chiefly upon (1) whether there is coexisting chronic myocardial or chronic valvular disease, and, if either be present, its nature and degree; (2) to a less extent, upon the average duration, the ventricular rate, and the degree

of cardiac failure during former attacks; and (3) the response to treatment—regarding which I shall say a word or two later on.

May I draw attention to the importance of examining the walls of other arteries than the radial, especially the brachial? How frequently is arterial disease excluded as the result merely of an examination of a short length of the radial artery alone! It is necessary to emphasize the great importance of accurately determining the size of the heart, more especially in cases in which the apex-beat is either faint or absent, and particularly in suspected chronic myocardial disease. I have been surprised at the comparative frequency with which these cases are overlooked—due, in my opinion, to a lack of appreciation of the great importance of determining accurately the size of the heart, and also to a lack of knowledge of the size of the normal heart in persons of varying size and physique. In any doubtful case the size of the heart should be determined by means of x rays.

Much valuable information may often be afforded by the cardiac sounds and the cardiac cycle. Thus: The first sound may be short, sharp, and clear, and diminished in intensity when the contractile force of the ventricle is reduced from any cause. What is called the tick-tack heart-beat or foetal rhythm signifies a greatly impaired vitality, and is often of grave omen. What is termed the gallop rhythm indicates either a failing heart muscle or a bundle-branch block, or possibly intraventricular block, and is almost always of very unfavourable import.

During recent years it has become rather the fashion not to pay much attention to murmurs, especially to those which are systolic in time. This is, I think, largely due to misunderstanding. As far as I am aware the older masters of clinical medicine were not accustomed to form a prognosis from the mere presence of a murmur. The point of practical importance is, What is the significance of the murmur? Thus, it is not justifiable to make a diagnosis of aortic stenosis from the mere presence of a systolic murmur over the aortic area, or of organic disease of the mitral valve from the mere presence of a systolic bruit over the apex of the heart, additional evidence being required in both cases. In every case in which an adventitious sound is audible over the precordium, the patient should be examined in the standing posture and on lying down, before and after gentle exercise, and during the various phases of respiration. In every case in which an adventitious sound is audible we should carefully consider whether it is exocardial or endocardial in origin, and, if the former, whether the murmur is organic or functional.

#### *Chronic Valvular Disease and Chronic Myocardial Disease.*

There is a tendency also not to pay much attention to chronic valvular disease. Now there are two points for consideration with regard to chronic valvular disease: (1) a valvular defect is a mechanical impediment to the heart muscle in its work; and (2) there are, as a rule, along with the valvular lesion, coincident changes in the myocardium, the aorta, or coronary arteries. I shall emphasize the great importance of the latter in a few moments. But that does not mean that a valvular defect may not be of great importance in itself.

In attempting to form a prognosis in any given case of chronic valvular disease, the nature, the extent, and mode of origin of the lesion, the condition of the myocardium, the amount of any existing degree of cardiac failure, the existence of complications, and the risk of sudden death are among those which require consideration. Of four varieties of chronic valvular disease, I should place in order of gravity aortic incompetence, mitral stenosis, aortic stenosis, and mitral regurgitation. With regard to aortic stenosis, however, a qualification is necessary; for although when due to a previous attack of acute endocarditis the prognosis is better than that of mitral stenosis, when primary chronic endocarditis is responsible it is not so good. Among the points which may be of assistance in trying to form an estimate of the extent of the lesion are: how far the character of the pulse and the blood pressure are modified, the size of the heart, and

whether the murmur merely accompanies or replaces the cardiac sound; and, in the case of aortic incompetence, the pulse pressure, and, in the case of mitral stenosis, the length of the presystolic murmur, and the presence and length of a diastolic murmur. Taking cases as a whole, when the lesion is due to a previous attack of acute endocarditis the prognosis is not so serious as when due to primary chronic endocarditis or to syphilis. With reference to the risk of the occurrence of sudden death in cardiac affections, a fatal issue in this way is most likely to occur in fatty or fibroid degeneration of the myocardium; it is also of not uncommon occurrence in angina pectoris; while of the valvular diseases it is most frequent in aortic incompetence, in which it is to be noted that sudden death may occur even when there are no indications of cardiac failure. Another cause of sudden death is complete and abrupt closure of the lumen of a coronary artery or one of its main branches. I shall deal with the myocardium and cardiac failure separately.

We now pass to the most important part of our subject. I have already remarked (1) that it is chronic myocardial disease, occurring *by itself*, which is so frequently missed, and (2) in the case of chronic valvular disease it is of the utmost importance that we should endeavour to ascertain whether the lesion which has invaded the valve has also affected the myocardium, the aorta, or coronary arteries. Now with regard to the investigation as to whether the myocardium is involved or not, and if so to what extent, I have referred to the significance of auriculo-ventricular block, branch-bundle lesion, intraventricular block, auricular fibrillation, auricular flutter, paroxysmal tachycardia, the size of the heart, and various modifications of the cardiac sounds and of the cardiac cycle. It remains to add and emphasize the extreme importance of ascertaining *how the heart responds to effort*; in other words, the amount of physical exertion in which the patient can indulge without experiencing symptoms of cardiac distress. I would urge that you should conduct a searching inquiry with regard to this in every case. In conducting this inquiry it is essential at the outset that three facts should be borne in mind. The first is that the natural standard of the heart's strength varies in individuals, each individual knowing the kind and amount of exertion in which he can normally indulge without producing symptoms of cardiac distress, and being aware when there is any departure from this, and to what extent. Our inquiry should aim at finding out whether the normal standard of a patient has decreased, and, if so, to what extent. The second fact which should be borne in mind is that symptoms of cardiac distress on exertion may be due to causes other than heart disease. Thirdly, the cardiac muscle may be merely temporarily exhausted, and this may occur whether the heart is diseased or not. But, provided extrinsic and temporary causes—such as anaemia, sleeplessness, temporary physical or mental strain, deficient tone due to lack of physical exercise—can be excluded, the fact of a departure from the normal standard of an individual, and its degree, may be taken as fairly indicative of the presence and degree of myocardial disease.

In the great majority of cases the first indications of heart failure are symptoms of cardiac distress on exertion, and it is only afterwards that objective signs—such as increased pulse rate, dilatation, or dropsy—appear. These symptoms occur as the result of less and less effort, until ultimately some or all of them are present, even during rest, and objective signs also become evident. The commonest symptoms are breathlessness, palpitation, fatigue, and precordial pain, on exertion. Breathlessness is perhaps the most important symptom of all. The most characteristic feature of pain due to heart disease is that it is brought on by exertion—though it should be noted that the pain may not come on until some hours after the exertion which has induced it. The site of the pain may be over any part of the precordial area. The pain of angina pectoris is felt most commonly in the retro-sternal region, next most frequently across the front of the chest, and occasionally in the precordium, the epigastrium, or over a wide area of the back of the chest, and has a tendency to radiate in certain directions. Cerebral symptoms may be due to cardiac causes. Among these

# ANAESTHESIA IN RELATION TO CARDIO-VASCULAR AFFECTIONS.

THE BRITISH  
MEDICAL JOURNAL 883

symptoms are giddiness, syncope or fainting attacks, attacks resembling *petit mal*, and Adams-Stokes syndrome. While giddiness and syncope may occur in heart disease, they are frequently due to vasomotor derangement, in which connexion it is of fundamental diagnostic importance whether they are more associated with physical exertion or change of posture. What is called cardiac asthma may occur.

It has occurred to me that it might be helpful to you if I indicated what, speaking broadly, may be regarded as clinical manifestations of four degrees of cardiac failure—namely, slight, moderate, severe, and extreme. Slight: Shortness of breath, palpitation, exhaustion, and it may be, precordial pain, on exertion which the patient formerly could undergo without experiencing this. Moderate: Shortness of breath, palpitation, and, it may be, cyanosis, on moderate exertion, such as walking quickly on the level; puffiness round the ankles in the evening; some degree of increased rapidity of the pulse while at rest; slight enlargement of the liver. Severe: Shortness of breath on slight exertion, such as walking at the ordinary rate on the level, or on changing position in bed; cyanosis while at rest; a considerable degree of oedema of the lower extremities in mitral cases, and a moderate degree of cardiac enlargement; a considerable degree of tachycardia while at rest; oedema of the bases; a moderate degree of hepatic enlargement; albuminuria; orthopnoea; cardiac asthma. Extreme: Continuous shortness of breath; severe dyspnoea on slight exertion; marked cyanosis while at rest; general anasarca in mitral cases, and a considerable amount of oedema of the lower extremities in uncomplicated aortic cases; oedema of the serous membranes; much hepatic enlargement; pulsus alternans in the absence of a severe grade of tachycardia. A point of the utmost prognostic importance in angina pectoris is the ease with which the pain is provoked, and whether it occurs even when the patient is at rest.

I now pass to some therapeutic considerations. These are germane to the purpose of our discussion, for the following reasons: I am strongly of opinion, and would with great earnestness submit it for your consideration, that not infrequently fatalities occur during induction of anaesthesia which might be avoided if advantage were taken of certain therapeutic measures which are clearly indicated. I am bound to say that I have been much impressed with the frequent lack of due preparation shown, as far as the heart is concerned, in the case of operations on the subjects of cardio-vascular affections. May I give you some examples of this? Most unfortunately a considerable proportion of patients with cardio-vascular affections endeavour, or are compelled, to live beyond the limit of the heart's strength, with the result that their hearts are constantly tired. I have merely to mention the inadvisability of operating on the subject of a cardio-vascular affection at a time when the heart is exhausted, and of the importance of postponing the operation until the patient has had a period of rest adequate for a full restoration to the normal level of cardiac strength whenever possible. Again, in the cardiac failure due to a rapid ventricular rate associated with auricular fibrillation or auricular flutter, the results of the administration of digitalis in the majority of cases are very, and in some cases extraordinarily, good. This usually occurs within a week, and sometimes in three or four days, after the commencement of full doses; if the case is more urgent, a physiological effect is usually obtained in from twelve to thirty-six hours from the oral administration of massive doses, while in still more urgent cases, or when the patient cannot tolerate any of the other preparations of the digitalis series of drugs by the mouth, improvement commences within about two hours and becomes very pronounced six to ten hours later after an intravenous injection of quinidine phanthin. In paroxysmal tachycardia 5 grains of quinidine sulphate once daily in the intervals between the attacks is usually successful in preventing their occurrence. In Adams-Stokes syndrome due to complete heart-block 5 to 15 minims of a 1 in 1,000 solution of adrenaline hydrochloride is often completely successful. Lastly, I would remind you of the value of venesection in certain cases of supernormal blood pressure, for while its effects are usually transient

they are of sufficient duration for the purpose of an operation. I would, therefore, earnestly plead the importance of taking full advantage of modern cardiological therapeutic measures whenever possible.

The question of the choice of anaesthetic does not lie strictly within my province, and in any case experts such as you are more competent to deal with it. I would, however, ask leave to make a few observations. The symptoms of cardiac failure in mitral disease are principally respiratory in character. The symptoms of cardiac failure in aortic disease are at first usually mainly those of systemic anaemia, there being little or no chronic venous congestion. The chief danger is syncope, and it is important to avoid lowering the blood pressure. Later on symptoms of relative mitral incompetence are apt to appear. Syncopal attacks are also the chief danger in fatty degeneration of the myocardium, and the blood pressure is almost always low in this affection. In fibroid degeneration of the myocardium, while there is also a danger of syncope, the clinical picture approaches more that of chronic venous congestion, and the blood pressure is usually normal or above the normal. In subnormal blood pressure the obvious indication is at least to avoid a further lowering; whereas the opposite is the case in supernormal blood pressure, arterial disease, and aneurysm. In angina pectoris it is of especial importance to avoid an increase in the blood pressure, unless this is materially below the normal. In auricular fibrillation it depends upon whether the symptoms of cardiac failure are mainly respiratory in character, or mainly those of systemic anaemia; they are usually the former.

With regard to the use of chloroform: Deep chloroform anaesthesia may induce heart-block in animals, which suggests that pre-existing mild heart-block in man may be increased by chloroform. I would also emphasize the great importance of avoiding irregular or intermittent administration during induction, and light anaesthesia; not commencing the operation before the patient is completely under; and the patient should be allowed to come out of the anaesthetic quietly.

Lastly, the foregoing considerations apply to the cardio-vascular affections, such as the age of the patient, whether he is of a robust or asthenic type, whether he is of a nervous disposition or not, whether he is addicted to excess of alcohol, and the nature and duration of the operation, have almost always to be taken into account. I venture to hope that, if the observations I have had the privilege of making to you are put into practice there will be fewer fatalities, and also that it will be possible to perform operations which are indicated on surgical grounds but which otherwise it would not be possible to undertake.

II.—JOSEPH BLUMFIELD, O.B.E., M.D.,  
Senior Anaesthetist and Lecturer on Anaesthetics, St. George's Hospital.

LOOKING back on some twenty-eight years' experience as an anaesthetist and reflecting on the occasions on which cardio-vascular affections have played a part in the case which was being dealt with, two facts become prominent. The first is the number of times that patients have been encountered who had been told by medical practitioners that they "could not stand an anaesthetic on account of the heart," and the second is the minute space occupied by chronic valvular disease of the heart in any list that could be compiled of anaesthetic fatalities gathered from private and hospital work, both personal and that of colleagues. This is the more notable because there is scarcely a variety of chronic valvular disease which has not been present in one or other of the patients in such a series who have passed safely through anaesthesia and operation. Generally speaking, it can be truly said that patients with heart affections do not give difficulty to the anaesthetist, the reason no doubt being that with a poor circulation go a poor physique and feeble muscular development, and consequently a type of individual who passes easily into anaesthesia without undue spasm or excitement. Nevertheless, it would of course be foolish to underestimate the risk which may be introduced into a case by the presence

of chronic valvular disease. When what is called "compensation" has broken down and there is shortness of breath then the subject of chronic valvular disease, if he must undergo operation, offers perhaps as critical a risk as any the anaesthetist is asked to meet. Even in such cases, however, when an operation is urgently necessary and the surgeon wishes to perform it, the anaesthetist need, in my opinion, never refuse the risk. There is always some form of anaesthesia or analgesia which can meet the demands of the situation, and although the inhalation of an anaesthetic may not be possible with safety, it is rarely indeed that the requirements of the surgeon cannot be met either by a regional analgesia, by rectal infusion, or by some combination of hypodermic injection with a minimal inhalation of nitrous oxide and oxygen, supplemented possibly by a very small amount of ether. The anaesthetist is not expected or required to make a diagnosis between the various kinds of cardio-vascular affections. What is, however, expected of him is that, confronted with a patient who is affected in one of these ways, he will be able to give a confident opinion as to the propriety or not of administering an anaesthetic at all, and if one is permissible he must be able to decide what it should be, how it should be given, and also to give it with safety. For these purposes we may consider the chief symptoms exhibited by the class of patients with whom we are dealing, and how these symptoms affect the anaesthetist's decision and procedure.

The most important symptom in a cardio-vascular case, from the anaesthetist's point of view, is breathlessness. When the patient cannot lie in the ordinary supine position with one pillow beneath his head without becoming breathless, whatever the exact change within the circulation which causes this symptom, the anaesthetist has a dangerous case to handle. Exactly how to meet the circumstances must depend partly on the site and nature of the operation to be performed, but certain principles will have to be observed in any case. First, the patient must be given his anaesthetic in that position in which respiration is most easily carried on; and secondly, in the administration of the anaesthetic, either no air limitation must be practised, or else air must be substituted by a free supply of oxygen. The great danger in this class of case is the introduction of any asphyxial element into the administration. The avoidance of this entails the avoidance of all spasm during the early stages of narcosis, and it is here that the anaesthetist's skill will be most severely tested. It is the not infrequent appearance of spasm in the upper air passages during the early stage of "gas and oxygen" anaesthesia that makes this method not always applicable (as at first sight we would expect it to be) to the kind of patients who are now under consideration. So vital do I believe it to be to avoid spasm and anoxaemia in these people that I would rather give even pure chloroform, if I believed that a quiet narcosis without muscular excitement during induction could be obtained with it, than the "safe" nitrous oxide and oxygen, if from the patient's build and the configuration of his mouth and pharynx I believed that spasm would be sure to arise during the inhalation of the gases. Whatever anaesthetic is used, oxygen should be given with it if the operation is at all prolonged, and, of course, every means necessary must be employed to ensure a perfectly unobstructed oral air way throughout. In association with shortness of breath I should like to mention a simple test which is invaluable in estimating a patient's capacity to undergo general anaesthesia. Without being obviously breathless, if a patient cannot, after taking a deep inspiration, hold his breath for thirty seconds then that patient almost certainly has a heart muscle which is poor and likely to fail if exposed to severe strain by any operation and anaesthetic. The use of this simple test will often put the anaesthetist on the *qui vive* in cases of myocardial degeneration, in which the patient's general appearance and the character of the pulse might not have led him to suspect the presence of risk. Auscultation will in such a case perhaps confirm the suspicions aroused, the first sound of the heart being found short and high pitched, and weak, or having a tick-tack rhythm. In the presence of these signs and symptoms the anaesthetist will be well advised to avoid the use of chloroform and to include some ether in whatever inhalational method he

adopts. Poor quality of the heart muscle is the bugbear of the anaesthetist, whether it is due to fatty change or to myocardial degeneration of another kind. For this reason very obese people are poor subjects for severe operation, and also those who have for long harboured some focus of septic infection. It is in cases of myocardial degeneration without marked symptoms that the anaesthetist needs the co-operation beforehand of the cardiologist.

Stress need not be laid here on the great advantage of always letting the anaesthetist examine the patient on a day previous to that of operation when circumstances permit. When he makes this examination on a patient with myocardial inefficiency he will discover the need for more accurate knowledge of the heart's condition, and this will be supplied to him by the heart specialist with his electro-cardiograms. In cases of advanced degeneration, when there is dilatation of the heart and swelling of the ankles, help is not so necessary, because the condition is obvious; but this is not so in the early stages of degeneration, when the anaesthetist may detect nothing but a small feeble pulse, and an altered first sound. When the anaesthetist has the opportunity of testing the effect of exercise on the cardiac rate he is greatly helped. When the normal increase in rate is exceeded and the return to normal delayed, the anaesthetist is put on his guard. Undue rapidity of pulse just before taking an anaesthetic is, of course, often merely due to nervousness; this rapidity diminishes as anaesthesia comes on. In other cases it is the effect of too much tobacco, and is then not steadied down by the anaesthetic. The rapidity associated with hyperthyroidism is evidence of a dangerous state, to meet which the anaesthetist has to take special measures, particularly beforehand, the details of which, however, do not rightly come within the limits of this paper. Generally speaking, slow pulses are favourable as regards inhalation anaesthesia. A fair proportion of perfectly healthy people, particularly males, have unusually slow pulses, a rate of 50 or less being not very uncommon. If with this slow rate of pulse there are no symptoms and there is no toxic condition present, the anaesthetist need take no unusual course; the patient will react favourably to the anaesthetic and there will be but little increase in the rate of the heart's action. When the slow pulse is due to heart-block the indication is more serious, but even in this condition long and severe operations have been safely carried out. A striking example may be mentioned in illustration of the capacity of a much damaged heart to stand operation when a suitable method of anaesthesia is adopted. These are abbreviated notes of the case.

A man, aged 60, was admitted to hospital in a state of collapse, and an injection of strychnine was administered in the surgery. Examined in the ward, he looked ill, and was found to have a temperature of 95° F., pulse 60, furred tongue, and pyorrhoea. There was a history of six months' constipation and indigestion, with intermittent pain about the umbilicus for the last five weeks. For the week before admission there had been hiccup and nausea; he had eaten nothing, and passed nothing by the bowel. He had attacks of a feeling of impending collapse, with numbness and tingling of the arms, but there had been no faintness, giddiness, or palpitation. The radial pulse was easily compressed; its rate was 60, with an occasional intermission. The heart sounds were soft and irregular, premature extra-systoles being superimposed on a triple rhythmic beat. The weak extra-systoles were followed by a compensatory pause. The jugular pulse showed numerous large and small pulsations. Later examination by electro-cardiograph showed an auricular rhythm of 75 and a ventricular of 40, with complete heart-block. The pulse had now settled down to an even rate of 36, which corresponded with the apex beat and the first heart sounds. The blood pressure was 145/58. There was an intermittent soft diastolic mitral murmur, and the first sound was accompanied by a harsh murmur, conducted towards the axilla. The abdomen offered some resistance to palpation in the low epigastric and umbilical regions. An x-ray examination showed some ballooning of the first part of the descending colon and a definite filling defect of the descending colon. The patient could walk a few paces without rise of pulse rate or feeling tired. The abdominal trouble continued, although occasional motions were passed, and a diagnosis of a growth of the sigmoid flexure was made. The surgeon in charge was anxious to operate, and the physician consented with reluctance, believing that the heart could not stand the strain of any prolonged anaesthetic. However, the abdomen was opened, a carcinoma of the sigmoid investigated, and a short circuit between the bowel above and below the growth was made. The anaesthetic employed was a mixture of two parts chloroform with three of ether for the first ten minutes of the administration, and pure ether for the remaining forty minutes. Both were given on an open mask under which a gentle stream

of oxygen was played throughout. The patient caused no anxiety during operation, and made a good recovery. The pulse rate did not rise above 50 per minute during the administration; it was 36 before this began.

Irregularity of the pulse is often met with, and in the absence of other symptoms need give the anaesthetist no concern. Generally the irregularity in otherwise normal persons persists during anaesthesia. When the irregularity has the form of *pulsus alternans*, or when the irregularity is extreme, or when there is undue rapidity of the pulse, the anaesthetist must mistrust the cardiac condition, and a special examination by a cardiologist is necessary.

We may now consider the bearing of the blood pressure upon the use of anaesthetics. With regard to excessive pressure, it is remarkable how few accidents have been attributable to this condition. It is often the case that persons with a blood pressure much above the normal have to be subjected to operation before time can be taken to reduce the plethoric state. These people are precisely those who are most apt to pass through a time of violent spasm and breath-holding during the induction of anaesthesia; at this time the blood pressure is, of course, enormously raised, and everything favours the rupture of a blood vessel. This accident, however, is of the rarest occurrence, and a search through the literature, as well as through personal experience, brings to light only two cases of positive haemorrhage and one case of hemiplegia which could reasonably be attributed to the action of an anaesthetic in patients who were the subjects of abnormally high blood pressure. When the pressure is unduly low the danger is, of course, that a still further lowering, produced by shock during operation, may result in syncope. In extreme cases it is desirable, whenever circumstances admit, to raise the pressure by intravenous infusion and by warmth before operation is undertaken. The use of warmed ether will generally then enable the anaesthetist to get any patient safely through operation; but these persons give great anxiety afterwards when the stimulation of the ether has passed off. It is with the people in the condition outlined above that the use of hypodermic injection of morphine before operation is particularly dangerous. In the subjects of abnormally high blood pressure, on the other hand, preliminary injections of morphine and of scopolamine are often of the greatest service.

In giving anaesthetics to patients suffering from aneurysm, as to those with unduly high blood pressure, the problem is how to induce anaesthesia with the least possible muscular excitement. It might seem that in these cases chloroform should always be chosen as producing so much less stimulating an effect on the circulation. It often happens, however, that nitrous oxide or ethyl chloride is preferred, followed by ether, because of their rapid induction. The patient must be regarded as a whole, and not simply as an example of aneurysm or of supernormal blood pressure. This general survey will often convince the anaesthetist that the safest mode of anaesthesia—that which is most quickly and most quietly effective, and therefore puts the least strain on the circulation—is just one which might often, *qua* circulatory system, be the least desirable. The newer anaesthetics, ethylene and propylene, appear to offer particular advantages in cardio-vascular conditions, for they can be used with large proportions of oxygen, and they do not give rise to great spasm. Experience, however, is as yet limited with these agents, and in the case of ethylene the appearance of irregularity with rapidity of pulse in several cases in which the heart has been normal make me chary of pronouncing as yet a very favourable opinion.

#### DISCUSSION.

Dr. ERNST VON DER PORTEN (Hamburg) said that the non-organic cardio-vascular diseases were of more interest to the anaesthetist than the muscle and valve diseases of the heart, which had often been called contraindications to general anaesthesia. The patient with a so-called organic disease of the heart was a bad risk patient in the wider sense of the word, but the degree and seriousness of his disease and his consequent danger from being anaesthetized could be estimated fairly exactly. On the other hand, the

patient suffering from cardio-vascular symptoms without organic basis was usually treated with particular respect by the anaesthetist, who was always afraid of surprise symptoms of collapse. In such cases there were two points to be watched with special care: The patients should come to the anaesthetic room carefully prepared and calmed by adequate doses of morphine; and secondly, in these cases anaesthesia should be as light as possible. Patients with a Basedow goitre should never, for instance, be so far under as to abolish the corneal reflex in both eyes.

Dr. A. L. FLEMING (Bristol) joined issue with Dr. Bloomfield as regards the necessity for the anaesthetist diagnosing the heart lesion. He maintained that the anaesthetist should know what type of lesion he had to deal with, and should make the examination and diagnosis himself. It was of the utmost importance in cases of cardio-vascular disease that plenty of time should be given for induction to avoid spasm and consequent heart-strain.

Lady BERRY (London) said she rarely gave an anaesthetic in cardio-vascular cases without a physician's report: patients with tachycardia and even with cyanosis could be prepared by rest and digitalis. She never gave a preliminary dose of morphine and always gave atropine. Slow induction was very important. She always gave open ether, and had a strong objection to nitrous oxide and oxygen in goitre cases. She always used the Rochester method of open ether, and the result of her inquiries from patients was that the induction by this method did not seem long. She kept the anaesthesia as light as possible all the time, compatible with real surgical anaesthesia, and carefully followed the respiration throughout.

Dr. H. M. COHEN (Manchester) raised the question of the relative importance of the systolic and the diastolic pulse pressure.

Dr. J. C. BRAMWELL (Manchester) said that the pulse was the most important indication of a patient's condition both to the anaesthetist and to the cardiologist. Irregularity of pulse was merely an outward indication of more profound disturbance in the circulation and heart mechanism. Syncope on the whole was due to a disturbance of the vasomotor mechanism rather than to a primary disturbance in the heart, and, excluding aortic disease, Stokes-Adams syndrome, and fatty and fibroid degeneration of the heart muscle, it was rare to find syncope due to heart disease rather than to disturbance of the vasomotor mechanism. Bradycardia was common in good athletes, and the pulse rate was often 50 or less. A man was a good athlete because he had bradycardia. If his pulse rate rose to 150 on exertion his recuperative power was as 3 to 2 compared with a rival whose normal heart beat was 75 increased to 150 on exertion. *Pulsus alternans* was of very grave significance when not associated with a rapid heart beat.

Dr. H. W. FEATHERSTONE (Birmingham) found that cases with extra-systoles went through ether anaesthesia well and in many cases the extra-systoles disappeared in the course of the anaesthesia. The choice of an anaesthetic was a responsibility in the case of a patient with a high blood pressure. Chloroform gave bad results; spinal anaesthesia was also undesirable.

Dr. H. P. FAIRLIE (Glasgow) stressed the importance of assessing the risk before giving anaesthetics. The bad risk patient gave less trouble on the table than afterwards. The anaesthetist in these cases should be guided by the physician.

Dr. S. R. WILSON (Manchester) advised co-operation between the physician and the anaesthetist, the choice of the anaesthetic to remain with the anaesthetist under the advice of the physician. Digitalization was useful, but he desired information as to the influence of morphine and atropine in cases of heart-block.

## THE EVOLUTION OF ANAESTHESIA.

Dr. S. R. WILSON (Manchester) prefaced a lantern lecture on the evolution of anaesthesia by emphasizing the great need that existed for improvement in the administration of anaesthetics for dental surgery, especially when the latter was carried out in the patient's home or in the surgery of the dental practitioner, where an operating theatre was not available. Preliminary preparation of the patient was not habitually possible. The surgeon was working against time, and there must be no risk of life to the patient either from the operation or the anaesthetic. Recovery must be rapid, and the patient, if not already there, able to go home in a short time. The case was complicated by the fact that the area of operation was common both to the surgeon and the anaesthetist. It had also to be borne in mind that suddenly and without warning the dentist might be faced with a situation of such difficulty as would require, if a general surgeon were dealing with the case, an anaesthetic lasting as long as two hours.

He noticed that a committee was now sitting to investigate the impurities in nitrous oxide gas as commercially provided, and the effects of these impurities on the patient. He would like to draw attention to a paper, published as far back as 1914, on this very subject by two Manchester dental surgeons, Hart and Minshall, which was full of information that had been practically ignored by the profession. The reports of the committee so far published were emptier of information than that of the two investigators he cited. However, the way of the pioneer was proverbially a hard one, and in his own experience twenty years had passed before the authorities awoke to the fact that there was need for a committee of investigation into the question of mule-spinner's cancer, a condition he had described when a house-surgeon.

There were three periods in the evolution of anaesthesia. The first, or pre-anaesthetic period, dated from 850 B.C. to A.D. 1776. The second, or "dawn of anaesthesia," dated from A.D. 1776 to 1844-46; while the third, or period of anaesthesia proper, dated from 1846 to the present day. Homer or Melisagenes, the blind poet of Chios, flourished in Greece circa 850 B.C., and the first reference to anaesthesia proper occurs in the *Odyssey*, the anaesthetist being Helen of Troy, who placed a drug in the wine whereof the soldiers drank. From this they might learn the lesson of pre-anaesthetic medication. Why had there been so much discussion on preliminary medication? Pavlov's work might eventually lead to the clarification of their ideas on this subject. Contrary to the usually accepted ideas, bromides act by brain stimulation and not by brain depression, and in the speaker's opinion caffeine would probably prove to be the drug they had been looking for all these years. Strychnine acted like caffeine. Orpheus was the first example of one who managed his patients by psychological methods, whereas when Elijah restored to life the widow's son he applied the excellent method used in anaesthetic overdose, and one which the speaker had employed with success on several occasions—oral insufflation by means of a tube, at the same time compressing the nostrils. This method could be employed at almost any place where surgical operations were done, as no elaborate apparatus was necessary, since all that was required was a couple of feet of rubber tubing, which was practically always at hand. Galen, who flourished between A.D. 130 and 200, and who for a thousand years supplied Europe with all that Europe knew of medicine, was practically silent on the subject of anaesthesia. He merely stated that mandrake had the power of paralysing sensation and motion. On the other hand, Dubartas (1544-1550) gave a perfect picture of anaesthesia in one of his poems. The speaker, when a youth, had a very poor opinion of poets as a race, but in his comparative old age he was being converted into thinking that, after all, they might have some use, and he almost admitted that he was able even to see beauty in some of their compositions. Shakespeare, in *Cymbeline*, Act i, Scene 6, depicted the queen, the wife of Cymbeline, in consultation with one Cornelius, a physician. She was a lady of racy language, who reminded him of the duchess who

hitherto had not taken part in the conversation. She says:

"Having thus far proceeded,  
(Unless thou thinkest me devilish,) is't not meet  
That I did amplify my judgement in  
Other conclusions? I will try the forces  
Of these thy compounds on such creatures as  
We count not worth the hanging, (but none human,)  
To try the vigour of them, and apply  
Allayments to their act; and by them gather  
Their several virtues and effects."

Cornelius was, however, doubtful of the bona fides of the lady, and, after receiving his congé, said in an aside:

"I do not like her. She doth think she has  
Strange lingering poisons: I do know her spirit,  
And will not trust one of her malice with  
A drug of such damn'd nature. Those she has  
Will stupefy and dull the sense awhile;  
Which first, perchance, she'll prove on cats and dogs,  
Then afterwards up higher: but there is  
No danger in what show of death it makes,  
More than the locking up the spirits a time,  
To be more fresh, reviving."

Here, then, they had an excellent definition of what an anaesthetic should be, and moreover the true spirit of scientific research, dependent on experiments on animals.

The dawn of anaesthesia commenced with Priestley, who, destined for the Church, renounced the idea and became a scientist. Possibly the emanations from a neighbouring brewery had something to do with the trend of his researches and led him to the discovery of nitrous oxide and other gases, for he was born near a brewery. Priestley was, however, apparently unaware of the anaesthetic properties of his discovery, and it was left to Sir Humphry Davy to suggest that the gas might be used to lessen the pains of surgery. The suggestion, however, lay buried in his works, and it was not until Henry Hill Hickman (1800-29) devoted his short life to researches into carbon dioxide gas, nitrous oxide gas, and asphyxia that Davy's suggestion was carried into practice. The inborn opposition of the profession as a whole to any novelty was as strong in those days as in any other period of the history of medicine, and Hickman's discoveries were neglected and almost laughed at. He went to Paris, where he was met with a little more sympathy, and a committee of the Academy of Medicine there was appointed by the King to inquire into his discoveries and to report thereon. But nothing further ever came of this second attempt of Hickman, and he died a few years later a disappointed man. Crawford Long took up the tale, and it is a remarkable fact that it was his good fortune to lead a placid and happy life and to enjoy a contented old age. On the other hand, Horace Wells and William Morton both passed through a short, stormy, embittered career, and in fact it would appear as though the pursuit of anaesthesia by the pioneer workers in that art was dogged by a malignant and malevolently implacable fate, which eventually impelled those in search of the relief of pain during surgical operations to end their careers by a self-inflicted death, after a life of intolerable distress and disappointment.

## VACCINE THERAPY IN A CASE OF ACTINOMYCOSIS FOLLOWING EXTRACTION OF A TOOTH.

This case is of unusual interest, since on the one hand the intelligent observation of the patient led to the diagnosis, and on the other hand her intolerance of iodides led me to the use of vaccine therapy. I have also waited two years in case there should be any recurrence of the disease.

Miss P. L., aged 17, had her second left lower molar tooth extracted in July, 1924. She went on her holidays, during which period an abscess formed in the tissues around the region of the extracted tooth; this was treated by poultices and other fomentations, but as soon as the abscess had drained itself and healed this was followed by a further abscess formation and rupture of its contents. There being no cessation of these abscesses the patient consulted me in September, 1924, two months after the commencement of her trouble. I found a dusky red area, triangular in shape, the base of the triangle being below the

left lower mandible, about three inches in extent; the apex of the triangle extended to the lower border of the left malar bone. Within the left cheek I felt a hard mass about the size of a shilling, which I attributed to a metastatic pyaemic deposit.

During the following month I made periodically free incisions into the abscess-forming area, so as to allow for efficient drainage. On October 31st the patient noticed some small "grains" upon the dressing which she was about to discard, and brought it straight to me for examination. On examining the granules under the microscope the usual filamentous network of the *Streptothrix actinomyces* was revealed. I sent a specimen to Dr. White, the district infirmary pathologist, who confirmed the diagnosis.

The diagnosis thus confirmed, the patient was put upon potassium iodide, but unfortunately, after a month of gradually increasing doses, she became intolerant of the drug, and was looking ill and losing weight. I therefore resorted to vaccine treatment. Messrs. Parke Davis supplied me with a vaccine containing 100 million actinomycosis fragments per c.cm. Intramuscular injections were given as follows: November 10th, 1924, 0.25 c.cm.; November 17th, 0.5 c.cm.; November 24th, 0.75 c.cm.; December 1st, 1 c.cm. Up to this period great improvement took place, but after the 1 c.cm. injection the affected area became very dusky in colour, the surrounding tissues were very much thickened and infiltrated, and there was every appearance of a further abscess formation; the patient herself was feeling far from well.

Presuming this to be due to some reaction taking place, I reduced the dose to 0.3 c.cm. of the vaccine, and kept to this dose weekly, from December 8th, 1924, to June 11th, 1925, with very satisfactory results—abscess formation ceased and the whole inflammatory area cleared up. At the present time the patient has regained her health and weight, and at the seat of the lesion there are some small scars, which in time will become scarcely perceptible.

It appears that the nidus of infection was in the cavity of the carious tooth. The case illustrates the importance of examining microscopically the pus of obstinate abscesses and sinuses after tooth extraction, and indicates that on the diagnosis being made, early treatment by vaccine therapy should be resorted to, especially when the patient shows iodide intolerance.

# SUBARACHNOID HAEMORRHAGE AS THE FIRST EFFECT OF A CEREBRAL TUMOUR.

THE following case of cerebral tumour with unusual symptoms seems of sufficient interest to be placed on record.

A man, aged 39, was admitted to the General Hospital, Birmingham, under Dr. Stanley Barnes on July 23rd, 1926. He had a long syphilitic history, having first contracted the disease in 1918. He was treated at the venereal clinic of the General Hospital over the whole period of seven years. The Wassermann reaction of the blood had been negative from 1922, and he had attended once or twice a year since for examination. For some weeks previous to admission he had suffered from intermittent attacks of giddiness and headaches, the headaches usually being preceded by a smell of burnt milk.

On admission he was only partly conscious and had a total paralysis of the left arm and leg. Lumbar puncture was performed and the cerebro-spinal fluid was found to be uniformly mixed with blood. The Wassermann reaction, both of the cerebro-spinal fluid and of the blood, was reported to be negative in each case. He recovered consciousness the following day and then had a severe headache in the right frontal region, which caused him to keep his right eye closed. No abnormality of the optic discs was found except some venous engorgement of the left.

For the next fortnight his condition seemed to improve; the paralysis cleared completely. About a week after admission there appeared the first signs of an exudate on the left optic disc. A month after admission he began to lose ground rapidly; he became more drowsy, the headache was worse, he was incontinent, and the optic discs both showed increased oedema and swelling, with numerous haemorrhages and complete filling in of the physiological cup. Further Wassermann tests of both cerebro-spinal fluid and blood were negative.

He died seven weeks after admission, and at the autopsy a tumour about the size of a Tangerine orange was found in the left temporo-sphenoidal lobe; there was a small aperture in the under surface of the tumour through which blood-stained serous fluid was still escaping into the subarachnoid space. Around this aperture there was a yellow clot from which the haemoglobin had been absorbed. The tumour was a gliosarcoma into which a haemorrhage had occurred.

It is thus clear that the slight early symptoms of headache and giddiness were coincident with the development of the tumour; that the first notable sign (unconsciousness and left hemiplegia) was due to haemorrhage into the tumour and rupture into the subarachnoid space near the apex of the temporo-sphenoidal lobe. The syphilitic infection had presumably no relation.

## Reports of Societies.

### TREATMENT OF CARCINOMA OF THE OESOPHAGUS.

At a meeting of the Section of Surgery of the Royal Society of Medicine on November 3rd, Mr. V. WARREN LOW (President) in the chair, the subject for discussion was the treatment of carcinoma of the oesophagus.

#### Surgical Treatment.

Mr. F. J. STEWARD, in opening, dealt first with palliative treatment. Since the outstanding symptom was dysphagia, due to mechanical obstruction by the growth, all forms of palliative treatment were necessarily directed towards the relief of this symptom. With this end in view the lumen of the stricture might be either enlarged by dilatation with bougies, or maintained of a size sufficient for the passage of fluids by tubes of various kinds, or increased by the destruction of the growth forming the wall of the stricture by diathermy or by radium. For many years now he had not used a tube of any kind for a case of carcinoma of the oesophagus: he had always advised gastrostomy. A Witzel's gastrostomy, if performed as soon as the diagnosis was made, was quite easy to manage after the first fortnight, so that the patient or his friends were able to administer the feeds without difficulty or discomfort and could soon learn to guard against leakage. He knew that gastrostomy for cancer of the oesophagus had a bad record and a high mortality. This was the result of the operation being done too late, and often as a placebo for a moribund patient after other treatment had failed. He pleaded for its early performance as a treatment *per se*. Perhaps the most definite advantage of gastrostomy lay in the fact that it was a source of real comfort to the patient and his friends as soon as they realized that it was a sure guarantee against death from starvation. This was more than could be promised when the stricture was treated directly, whether by tube or diathermy or radium. The consequent cessation of irritative symptoms resulted in a quite unexpected lengthening of the period of survival. Two of his patients had lived for five years, and there might be others.

Mr. Steward next turned to curative treatment. Radium had been disappointing in so far as actual cure was concerned. That radium could destroy the carcinoma of the oesophagus was certain, for ulcers and tumours that had been seen through the oesophagoscope, and had been proved by histological examination to be carcinomatous, had completely disappeared after treatment with radium. But this complete disappearance resulted in only a small proportion of the cases treated, and even in these the disease, with very few exceptions, reappeared sooner or later. With regard to the future of radium treatment, to his mind the hope of improved results depended upon earlier diagnosis, more exact knowledge of the extent of the disease, and more powerful dosage. Next he discussed the question of the excision of a portion of the oesophagus as a method of curative treatment. The factors which had led to failure were: (1) rapidly fatal infection of pleura or mediastinum or both; (2) such straitness of the oesophagus that there was no slack when it was mobilized, while on the other hand it retracted longitudinally in section; (3) the peculiar structure of the oesophagus, in particular the absence of a serous coat, and the softness of its walls, which in consequence would not hold sutures at all well; (4) the great difficulty in reconstruction of the oesophagus after resection for carcinoma and for cicatricial stenosis. He believed that only three cases were recorded in which patients had recovered from an operation for removal of a carcinoma of the oesophagus; the first was recorded by Torek in 1913, the second by Lillenthal, and the third by Eggers. The study of these three cases led him to the conclusion that it would be justifiable to attempt operation in cases in which the growth appeared to be small, localized to the oesophagus, and devoid of complications, provided that the patient was in good general condition and free from visceral disease. He had explored an oesophageal carcinoma with a view to removal on three occasions, the

ages of the patients being 51, 62, and 53. All three cases ended fatally: the first rallied well from the operation, but died suddenly the next day, the *post-mortem* examination revealing nothing to account for death; the second patient lived nine days, and the third did not rally from the operation. Notwithstanding this melancholy result there were certain encouraging features in these experiences which led him to the opinion that as technique improved better results might be looked for. He based this view on the following considerations: (1) The symptoms of the carcinoma were straightforward and distinctive, so that correct diagnosis at an early stage was not difficult. (2) The disease remained localized to the oesophagus for a considerable time in all cases, and during its whole course in a large proportion. (3) The successful performance of other operations involving the mediastinal portion of the oesophagus, such as operations for fibrous stricture of the oesophagus, clearly showed that from the point of view of technique the excision of a carcinoma of the oesophagus was practicable. (4) Although so few cases had been successful, the reported cases proved the possibility of cure by operation. (5) It was perhaps not unreasonable to hope that the history of the surgery of other organs might be repeated in the case of the oesophagus. With regard to the choice of operation, he had formed the opinion that for a growth at the lower end of the oesophagus Lilienthal's would be the more suitable, while for a growth in the middle third he would prefer the operation as described by Torek.

#### *The Intubation Method.*

Mr. H. S. SOUTTAR said that he felt rather shy, after the brilliant work Mr. Steward had described, in bringing before the Section the very simple method of which he himself made use, the more so as he was afraid he entirely dissented from Mr. Steward's views as to the operability of these cases. The ground on which it was suggested that these cases were suitable for operation was that no secondary growths were found. But how often did one find a secondary growth within one year after the origin of carcinoma of the breast, and how many cases of carcinoma of the oesophagus survived a year? He had examined eighteen *post-mortem* records at the London Hospital, from each of which it was obvious that the growth had reached an entirely inoperable stage, and the condition found inside the thorax and around the oesophagus could only be described as chaos. It might be said that these were old cases; but they had died quite soon after coming into hospital, from various causes, some of them after gastrostomies. The average duration of the symptoms was 4.7 months. The speaker had just reached his own hundredth case treated for carcinoma of the oesophagus, and the average duration of the symptoms at the time he first saw these patients was 4.8 months. Surely this supported his contention that at the time when these cases were first seen by the surgeon they were already in the penultimate stage of the condition which was found *post mortem*. He did not believe that 5 per cent. of the cases which came to the surgeon were operable, from the purely pathological point of view, at the time he saw them. It might be said that these cases came late; but the man who could not swallow came at once. Many of the cases that he had seen had come to him within a few weeks or even days of the appearance of their first symptoms, and even then the condition inside the thorax revealed by the oesophagoscope was staggering. Not only that, but many of the cases examined *post mortem* had never had any oesophageal symptom of any kind—the cancer of the oesophagus was found by accident. The first symptom of this disease, interference with swallowing, appeared only at a very late stage, and by that time operation, pathologically speaking, was out of the question. In any case he did not think personally, much as he would like to do it, that it was worth attempting. Even supposing that a few completely successful results after removal of the oesophagus could be pointed to, was the operation as a routine procedure thereby justified? This was not a rare disease by any means. In a very short time he himself—and he was not a throat surgeon—had collected through the kindness of his friends one hundred cases. The annual mortality from this condition in England and Wales

was 1,600. Moreover, could it be described as a cure if a section of the oesophagus were removed and the patient made unable to swallow? Many would prefer death to existence on those terms. To make the patients able to swallow comfortably until the end of their lives was all that it was possible to do in very many cases.

Intubation (Mr. Souttar continued) by the methods ordinarily adopted aimed only at the swallowing of fluids. In his own method he had provided for the swallowing of soft solids, and, after all, in the normal person, given effective mastication, soft solids were all that the oesophagus carried. He exhibited three of his oesophagoscopes tubes of different lengths, 10, 14, and 18 in., which afforded remarkable facility in handling the patient. With one of these in position, the next problem was to pass through the stricture, a delicate piece of work, in which one had to be sure that the stricture itself was entered. He used a modification of a Jackson bougie, and, controlled by the oesophagoscope, in the great majority of cases the bougie could be worked through. This accomplished, the surgeon's troubles were over. He then slid down dilators of increasing diameter, up to 11 mm., over the guide and through the stricture, after which one was in a position to pass a tube of reasonable dimensions. The tubes used were of German silver wire, flattened and twisted in a curious spiral so as to prevent regurgitation of the tube. Since this spiral twist was introduced he had not had a tube coughed up, which was a common event beforehand. The results in the great majority of cases were satisfactory, and the patient, exercising reasonable precautions, was able to sit down to dinner with his family. The patients were told to have everything minced because, as a rule, they had defective teeth. The average duration of life in twenty-six cases which he had followed up to a conclusion was 5.3 months. The prospect was melancholy, because these patients must be regarded as having a fatal condition. Most of them were persons of between 60 and 70 or over, and, after all, to enable them to swallow food for perhaps a year—one of his patients went on for two years, and several for eighteen months—and to make them comfortable was to do a great deal of good, and compared advantageously with the results of gastrostomy. But he certainly hoped that in time it might be possible, at least in a certain proportion of these cases, to resect the growth and obtain a complete cure.

#### *General Discussion.*

Mr. W. G. HOWARTH said that for the last sixteen years he had had the opportunity of looking after practically all these cases at St. Thomas's, and he had tried all the recognized methods, but particularly the radium treatment of the oesophagus, not only the method employed in this country (of small doses repeated at monthly or six-weekly intervals), but also the intensive method advocated by Guisez. He was profoundly disappointed with radium in this condition. He had also used diathermy, and once a suitable electrode was obtained the result was satisfactory for the time being, though, of course, neither radium nor diathermy was more than a temporary expedient. He favoured Mr. Souttar's method; to make the patients comfortable and able to swallow, at any rate for some months, perhaps longer, was no small achievement. One saw so many of these very advanced cases in the last stages that anything one could do to relieve their distress was of the utmost importance. Large numbers of them could not even swallow fluids, and to deal with their own saliva was one of their difficulties. On the day that Mr. Souttar published his paper in the *BRITISH MEDICAL JOURNAL* the speaker borrowed a tube from him and tried it in what proved to be his most successful case. It was that of an old lady, who lived for eighteen months with the tube in her oesophagus and had no difficulty in swallowing minced and semi-solid foods. With regard to Mr. Steward's observations about attacking the carcinoma externally, he had himself removed an oesophageal carcinoma from the upper end of the oesophagus and brought up the oesophagus to join the cut end of the pharynx. The patient was still alive after two years, and able with a minute aperture to get along fairly comfortably. His experience was that it

Nov. 13, 1926]

# MODERN ASPECTS OF SYPHILIS.

THE BRITISH MEDICAL JOURNAL 889

was very difficult to say what was going to be an operable case and what was not. On looking down the oesophagoscope and passing the bougies it was not easy to determine where the carcinoma was springing from, and still more difficult to determine the lower end of the growth.

Mr. A. L. AMZ, referred to the difficulties arising from infected teeth. All the teeth should be removed (or, if the patient objected to that, all the infected teeth) before either a tube was passed or radium introduced or an operation undertaken. With regard to the question of anaesthetic had been performed under a local anaesthetic, with stomies had been performed under a local anaesthetic, with no immediate mortality, and in no case the development of so-called bronchopneumonia. The way to measure the length of the carcinoma or of the stricture was first to x-ray the patient in the ordinary way, using an opaque drink; afterwards the patient was placed on the right side and an x-ray exposure made during the act of swallowing a bismuth solution. In this way one got an indication of the stricture not only from above downwards but from below upwards. If the stricture was probably operable, He had operated on a few cases through the mediastinum, one of the patients living fairly happily for eleven months afterwards. He thought there was no shock, or very little, from this operation, and it was not conceivable that the passing of a skin flap under the growth should add to the shock or danger. He had used Mr. Souttar's tubes in eight cases, but in four they were swallowed straight away, and in the other four the result was not very satisfactory. He pleaded for another attempt at surgical cure. Mr. Souttar had said that these patients came early; but they did not come to the surgeon early, though they might go to their own practitioner. They came to have a gastrostomy done. If the patient was to wait until he had only when somebody else thought it was time to have the gastrostomy done. If the patient was to wait until he had only when somebody else thought it was time to have the gastrostomy done.

Mr. T. B. LARSON said that a very small number of cases were suitable for operation; he was inclined to agree with Mr. Souttar's estimate of 5 per cent. Mr. Souttar had seemed to suggest that operation was not worth while, but surely it was worth while, even in a small number of cases, if the patient was fairly young. There were difficulties in selecting cases for operation. Mr. Souttar had suggested that when one looked down at the top of the growth through the oesophagoscope one could tell what condition it was in. The speaker did not think that much knowledge could be derived from the narrow part of the oesophagus, but gave much information from the shadows around the growth. An enormous amount of shadow in the area around the growth was probably an indication that the growth had already spread into the mediastinum, and that the case was not very suitable for operation. He agreed with Mr. Abel's remarks as to the importance of local anaesthetics, these should be removed very gently under local anaesthetics.

Dr. G. E. VILVANDRE spoke as one who had x-rayed a large number of Mr. Souttar's cases at the London Hospital—perhaps fifty during the last eighteen months or two years—and in only three or four had he found the tube phagel tube in the caecum or in any other part of the alimentary tract. In the great bulk of the cases the tube had proved quite efficient, to judge from the evidence of the barium meal.

Mr. E. D. DAVIS thought the dysphagia a very late symptom. Altogether he had done between seventy and eighty oesophagoscope examinations for carcinoma, and only one looked like an early case; all the others were advanced cases, and died within about eight months. With regard to Mr. Souttar's intubation expedient, he had had a certain number of successes in using the method, but those were cases in which the middle of the oesophagus was the part involved. At the cervical end of the oesophagus the patient would not tolerate this procedure, and at the cardiac end it was difficult and uncertain.

The PRESIDENT (Mr. Warren Low) said that his impression of these cases from the point of view of cure was rather gloomy; he would very much like to share the

enthusiasm of Mr. Steward and Mr. Abel. At the same time he could not help thinking that possibly they were right. Surgical experience with other organs had always started in this somewhat gloomy way, and then one or two pioneers had come along and had shown what could be done. But early diagnosis was essential. As it was not at first realized that this was an advanced case of oesophageal carcinoma. When the patient was questioned about his condition during the previous few months he would confess generally to vague pains in his chest, usually put down as "indigestion." He might have seen his doctor for these pains, or he might have gone to the *Daily Mail* and obtained his diet, and ate brown bread instead of white and afterwards "a little more vitamin"! Not until months afterwards was it discovered what was really the matter with him. If some frank symptom, such as the difficulty in swallowing, were awaited they would be landed with rather late cases. He had had no personal experience of Mr. Souttar's tubes, but he had seen a good many tubes used, and there seemed to him something essentially unsound in dilating a carcinomatous stricture. If any foreign body was in close relation with a carcinomatous surface there must be some irritation of that surface and some reaction, though at the same time undoubted relief was afforded so far as the difficulty in swallowing was concerned. He was in agreement with Mr. Steward that the best operative method was gastrostomy. Assuming that the carcinoma was inoperable according to present methods of examination, he was sure that an early gastrostomy was a wonderful comfort to the patient. The difficulty was the prejudice, not only of the public, but of the medical profession. He was constantly told of a doctor who had said, "I would rather die than have such a thing done to myself." But it must be remembered that the doctor was speaking from the point of view of a healthy man. The humanitarian value of gastrostomy was enormous. The high mortality of the oesophagus, he thought, was made too late. Carcinoma of the oesophagus, he thought, spread rather by implication of the surrounding structures than by the lymphatics. The patients died most often from invasion of the trachea or the aorta or general spread in the mediastinum. He had had several patients live for two years comfortably after gastrostomy. One patient of Sir Frederick Treves, many years ago, had a gastrostomy done for a large growth at the lower end of the oesophagus and lived for three and a half years afterwards. Mr. STEWART, in reply, said he was glad that the President had given him some support in his advocacy of gastrostomy. He had not used Mr. Souttar's tubes, but he had been impressed by what Mr. Souttar had told them, and he had no doubt that in Mr. Souttar's hands this was as good a thing as could be done for the patient suffering from inoperable carcinoma of the oesophagus. With regard to the operability of these cases, he did not want to suggest for a moment that every case should be operated on. No doubt it often happened that by the time the case came forward the mediastinum was in a state of chaos; but there were other cases in which the growth could be diagnosed while it was still limited to the oesophagus and with no signs of secondary deposits. He still maintained that if the gastrostomy were done early the patient would lead a more comfortable life than with the tube.

## MODERN ASPECTS OF SYPHILIS.

The first two meetings of the Royal Medico-Chirurgical Society of Glasgow were occupied with a symposium on the modern aspects of syphilis in special and general practice. The President, Dr. JOHN COWAN, occupied the chair. Dr. W. HENNERT BROWN, opening the discussion, limited himself to the earliest, or primary, stage of the disease in the male. In view of the amount of propaganda there had been, every member of the medical profession might have been expected to be familiar with the most important modern aspects, but this was not so, judging by the previous histories of some patients who came to venereal clinics. Patients sometimes presented themselves with secondary cutaneous and with tertiary syphilis, and it transpired that several weeks or months previously they

had had genital sores, which were treated by the physician in charge by local antiseptics, with or without mercury pills and potassium iodide. This was far removed from what ought to be done in such cases, since the sequelae were so serious. The key to preventing the ravages of syphilitic infection and the social and family calamities which followed was early diagnosis with early treatment. Few diseases were more amenable to treatment, if the diagnosis was made early and the best modern treatment undertaken. Every genital sore (venereal) should be considered as possibly syphilitic until the contrary had been proved. No one, however expert, was justified in assuring a patient, from one or even several examinations, that he had not contracted syphilis. There was still a prevalent impression among undergraduates and graduates that all syphilitic sores were hard, and that non-syphilitic sores, or "soft sores," were not infiltrated. This was quite wrong, since many characteristic syphilitic sores presented no induration and the Hunterian chancre was rather a rarity. The speaker divided venereal sores into three classes: those which were characteristic of syphilis from their clinical features, the doubtful sore, and those which were characteristic of the non-syphilitic, or soft sore. In the first instance the diagnosis should be clinched by finding the *Spirochaeta pallida*. In the doubtful sore, search should be made, not once, but several times if necessary, for the spirochaete, the patient be kept under strict supervision so as to detect further evidence of syphilis, and a Wassermann test be performed every week if necessary. All patients with non-syphilitic sores should be kept under observation for three to four months, and should not be dismissed as free from syphilis without one or more Wassermann tests. Dr. Brown then gave a brief outline of what he considered a satisfactory line of treatment. Comparing the common antisyphilitic remedies, arsenic, mercury, bismuth, and the iodides, he considered arsenic in the form of one of the salvarsan preparations as pre-eminently first, and the sheet-anchor for the great majority of cases of early syphilis, but it was desirable to supplement it by the slower acting remedies such as mercury, or its new rival, bismuth. For early syphilis the intravenous method of injection was the one of choice, but the intramuscular and subcutaneous injections of suitable preparations could be adopted if there were any contraindications to the intravenous route. The importance of a thorough general examination of the patient before starting treatment was emphasized, and the urine should be examined comprehensively before every injection throughout the course of treatment. The drugs used, their dosage, and the number of injections varied with each experienced worker. In this country the intermittent treatment was generally adopted, the patient being given a course of injections, next a period of rest for six or seven weeks, then another course, and so on until an adequate amount had been given. Dr. Brown described in detail the course of treatment he preferred, and said that practically every case of early primary syphilis with a negative Wassermann reaction should receive twenty to twenty-five intravenous injections of salvarsan and some sixteen or eighteen of mercury and bismuth, or mercury be given orally. The number of injections and mode of administration were determined by the general response of the patient and the serological tests.

Dr. MADELINE ARCHIBALD referred to her experience in a large industrial practice. She found the typical chancre of the textbook an uncommon phenomenon, and believed that syphilis was not so prevalent among manual labourers as among those whose occupations were sedentary. While the incidence of congenital syphilis in Glasgow had been variously estimated—as, for example, 10 per cent. (Findlay) and 8 per cent. (Elliot)—she had found the incidence of acquired syphilis to be at least 10 per cent., and possibly higher. While her conclusion might have been influenced by the fact that she was connected with a venereal hospital and a venereal clinic, she thought that her experience was not far removed from that of the average general practice in an industrial area. In the ordinary routine of practice, out of 400 patients who had had their blood tested 109 were discovered to have a positive Wassermann reaction; 70 of these were reluctant to admit the possi-

bility of syphilis and failed to recollect the existence of a primary sore. Only seven admitted the presence of a "text-book" genital sore. Throughout a period of ten or eleven months only five cases of primary chancre came under observation, though the case incidence in her practice was higher than that in Glasgow as a whole. Of these five, three were small macules occurring on the glans penis and discovered only because the patients, having been exposed to infection, had been conducting a daily inspection. Of the remaining two, one was labial with no induration and no glandular involvement, but with a snail-track mucous patch on the soft palate; the other was on the anterior lip of the cervix, with a macular rash on the chest.

The majority of observations of the primary sore had been made in the male, while the anatomical structure in the female rendered the detection of small sores difficult, and thus the disease in a woman might escape detection till the birth of a frankly syphilitic child, or even till the child-bearing period was passed and late symptoms suddenly manifested themselves. Dr. Archibald concluded by making a plea for the early administration of neokharsivan, even amidst the routine of a busy practice, providing always that the contraindications were kept in mind and brought to light by the ordinary simple clinical methods.

Dr. J. FERGUSON SMITH considered the situation where the infection was already generalized, as evidenced by a positive Wassermann reaction or a secondary rash. When it was remembered that the treponema could be detected in the blood of rabbits before even the primary lesion had taken clinical shape, they might well give late primary sero-positive and early secondary cases the benefit of intensive treatment. Although such intensive treatment subjected the patient to a definite risk, that risk was worth taking when the late results of uncured syphilis were considered. It was essential to keep a very close watch on the patient's general health so that signs of intolerance should be detected at once. Albuminuria in untreated secondary syphilis was an indication for caution in using neokharsivan, and not an absolute contraindication. Albuminuria developing during arsenical treatment was, of course, a very different matter. In recent syphilis the motto was, "Strike early and strike hard." Dr. Smith detailed the course of treatment for cases of tertiary syphilis, and gave statistics of 45 patients treated under the auspices of the Public Health Department of Glasgow for at least six months. Of the 45, 39 were clinically cured, 5 improved, and 1 unimproved. This last and two of the "improved" were cases of leucoplakia linguae. Fourteen had a negative Wassermann reaction, 21 were strongly positive, 4 were positive, and 3 were doubtful. Of those with a negative Wassermann reaction, 10 had been negative for over one year, and 5 of these for over two years.

Dr. W. H. SCOTT dealt with syphilis from the congenital aspect; the cases could be divided into infantile syphilis and lues tarda (symptoms appearing at or after the second dentition). Both of these classes presented difficulties in treatment peculiar to themselves. In the adult the main curative agent must be one of the organic arsenic compounds, and intravenous medication was the method of choice. In infants the injections could be given into the scalp veins, and the drug was tolerated very well. The dose per kilogram of body weight could be much larger than in the adult, and toxic symptoms were very rare. No case of toxic jaundice in an infant had been encountered, and it was an interesting fact that, although the liver appeared to be affected in practically every case of congenital syphilis, the use of a drug which, in adults, was markedly toxic to the liver, and especially to a diseased liver, was not dangerous. In older children the problem was much more difficult, both as regards technique and the amount of treatment required to produce cure. The dose could not be much higher than in infants, as children at this age did not show the same tolerance to the drug. The parents of all cases of congenital syphilis should be treated if possible. The mothers rarely showed any signs of the disease, but all had positive Wassermann reactions. Treatment during pregnancy was safe and the results good.

Dr. ALLISON McLAUCHLAN supported Dr. Brown's plea for early diagnosis and for efficient and prolonged antisyphilitic treatment. The combination of antisyphilitic remedies was,

# PROBLEMS OF ETHER ANAESTHESIA.

he thought, unnecessary; he was, indeed, inclined to consider their combined use as predisposing to some of the untoward effects of therapy. He was surprised at the high incidence of syphilis in Dr. Archibald's general practice. After making a plea for closer collaboration of the physician, neurologist, bacteriologist, and others in dealing with the many problems of syphilis, the speaker discussed the treatment of nerve and cardio-vascular syphilis. His own experience of the treatment of such cases by the more modern methods had been disappointing, and he was forced to the conclusion that, in the more advanced stages of the disease in these systems, the results of modern treatment showed little if any advance on those of the older-fashioned methods. While his experience had been limited, he was disposed to think that, if they excluded the group of cases presenting a positive blood reaction and little or no evidence of gross cardiac changes, but with subjective angina, irregularity, fatigue, and general respiratory distress, the use of salvarsan products did little good and might be distinctly harmful. In congenital syphilis he had found the results of salvarsan disappointing, not only in the infant born with active syphilis, but also in late congenital disease.

Dr. DOUGLAS ADAMS referred to the very wide range of the subject under review. The necessity of remembering the biology of syphilis was emphasized, and also the importance of research with reference to the causal organism, in which little recent advance had been recorded. Prophylaxis was of supreme importance, and the necessity of prolonged treatment, with subsequent lifelong observation of the patient, was urged. The literature of the pyrexial treatment was then reviewed, and attention was drawn to the fact that artificial pyrexia had been tried solely in late neurosyphilis. The results published were conflicting, and the difficulty of drawing definite conclusions was not lessened by the limitation of its application to types of the disease in which spontaneous remissions were to be expected. If it was thought that hyperpyrexia possessed definitely spirochaetocidal effect, would it not be logical to employ it in the primary stage of the disease rather than to defer its use until the patient was dying of general paralysis? Two aspects of neurosyphilis appeared to merit special consideration. In the first place, assuming that the original syphilitic infection had been either untreated or imperfectly treated, it was essential to recognize the earliest symptoms pointing to central nervous involvement, and to correlate these with the cytological and serological changes which, at this stage, were almost invariably found in the cerebro-spinal fluid. Energetic treatment could then be instituted before irreparable nervous damage had been done. In the second place, attention to the routine examination of neurosyphilitic material cut and stained by Jahnke's method revealed surprisingly scanty evidence of the presence of spirochetes. The experimental knowledge of *Spirochaeta pallida* was unsatisfactory, but a review of the literature revealed two important facts. The number of occasions on which *Spirochaeta pallida* had been successfully transmitted primarily to animals was very limited. In addition, the importance of *Spirochaeta cuniculi* as a source of error in experimental syphilis in rabbits had always to be borne in mind. Further research on the cultural and experimental properties of *Spirochaeta pallida* and of its distribution in the tissues held out the chief hope of a real advance in the knowledge of the subject.

Dr. T. K. MACLACHLAN said that in the treatment of syphilis of the nervous system, the older remedies, especially mercury, gave better clinical results than those of the salvarsan group. The best results were obtained in the varied clinical conditions grouped under the heading of meningo-vascular syphilis. Assiduous mercurial inunction pushed to the limits of the patient's tolerance should be the routine; potassium iodide should be added after four to six weeks, but not before, as the iodine promoted the elimination of mercury, which was the objective. It was advisable to give a course of neosalvarsan to stay the advance and to prevent fresh manifestations of syphilis. In the group formerly known as parasyphilis, since the main lesion was of the nervous tissue proper—the ganglion cells and fibres—tissue so specialized in function that when

damaged repair did not occur, it was not possible to recognize the possibility of a cure. In dementia paralytica though an associated meningitis and endarteritis might be treated and lead to some clinical improvement, yet from the vital nature of the cells and association tracts affected the outlook could not be good. In tabes dorsalis, on the other hand, the poisoned nerve fibres were not of such vital importance, so that if antisyphilitic treatment was instituted at an early stage the advance of the spinal disease might be stayed, and, by re-education of links, useful life might be made possible for years.

Dr. O. H. MAYON thought that Dr. Archibald's estimate of a 10 per cent. incidence was exaggerated. In two groups of medical wards at Stobhill hospitals the figures were: total number of patients 320, Wassermann tests performed in 92, positive results obtained in 19. The test was performed in all probable syphilitics, and in view of the part played by syphilis in so many "hospital" conditions the figures were remarkably low. The implication in Dr. Scott's paper that all infants showing a positive Wassermann reaction should be treated energetically with salvarsan preparations gave some cause for observed, late While no immediate toxic reactions were observed, effects on the reticulo-endothelial and endocrine systems must be borne in mind, as must also the fact that a proportion of these children did not have syphilis at all, and merely gave the reaction of the maternal blood. On the question of advanced arterial syphilis he could not take Dr. A. D. McLachlan's view that asymptomatic cases ought not to be treated. Nearly all late cases of syphilis showed arterial disease. There was a strong body of opinion against treating patients with gross manifestations. The action of potassium iodide was not properly understood, and the commonly accepted ideas were probably wrong. He suggested that specific intramuscular medication was followed by undoubted benefit if the following criteria were accepted: (1) Disappearance of bronchitis, (2) disappearance of cardiac pain, (3) correction of cardiac irregularity with consequent disappearance of dyspnoea, (4) consistent fall in blood pressure, (5) increased sense of well-being, (6) diminution in size of an aneurysm.

Dr. W. G. CLARK discussed the position of the Glasgow Medical School in connexion with instruction about venereal diseases. He thought it was a matter of regret that the material for the proper teaching of these diseases was passing from the general hospitals to *ad hoc* centres under the corporation, where teaching must become secondary to the speedy cure of the patient.

## PROBLEMS OF ETHER ANAESTHESIA.

At the opening meeting of the new session of the Section of Anaesthetics of the Royal Society of Medicine, on November 5th, Dr. Z. MENNELL, the new President, after briefly referring to the success of the Section during the past year and to the visits of fellow workers in the field of anaesthetics from the Continent and the United States, invited the meeting to discuss certain controversial issues connected with the administration of ether as an anaesthetic. Dr. Mennell asked first what depth of anaesthesia the ideal when teaching students. If the deepest possible under unmixed ether were they justified in indicating as the degree of anaesthesia was to be desired he wished to know whether this was safe, and, if not safe, what were the effects of over-oxygenation in the administration of ether? What was the cause of apnoea in the early stages of ether narcosis with the pupils widely dilated? He called attention to the valuable and interesting information that could be obtained from examination of the vocal cords during the administration of an anaesthetic. True abdominal relaxation could not be obtained until the abductor muscles of the larynx became paralysed. In the early stages of narcosis the cords were seen as white taut-glistening bands, but when the abductor muscles became paralysed these bands became pink and the tightness disappeared; it was only then that a really free airway was established and the abdominal muscles became relaxed. He mentioned a phenomenon which he called late jactitation. This was

entirely different from the ether clonus so frequent in the early stages of ether anaesthesia, since it occurred late in the administration of the drug and was always a danger signal. Apparently it was not associated with the degree of purity of the drug, since in all cases the ether used had been subjected to analysis and found free from impurities. Some of these patients had died at a later period, a few hours after operation, and the phenomenon appeared to be of grave import in prognosis. The speaker attributed it to prolonged deep ether narcosis, and to him it was an argument against the employment of this method of administration. In this connexion he referred to an anaesthetic fatality in which peripheral dilatation of all the small vessels occurred under deep ether anaesthesia, and reported two other cases. He attributed the result to prolonged over-stimulation combined with a falling blood pressure, and mentioned in this connexion Dale's researches on histamine. Dr. Mennell described a case of death from fat embolism which occurred under ether. The operation was concerned with correcting the position of the tendo Achillis, so that there was no free fat at the site of operation which could enter the circulation. In his opinion the ether had nothing to do with the fat embolism, and the case was a surgical curiosity. Slides showed large deposits of fat in the circulation of the kidney and heart muscle. His own views were that prolonged deep ether anaesthesia was to be avoided as it was not safe. It was necessary to produce a preliminary deep narcosis with ether to ensure relaxation, but once this had been reached it was not necessary to maintain this great depth, and the pupils could be kept only moderately dilated. Over-oxygenation was to be avoided as it had undesirable after-effects.

Professor DUNGERON could not explain the mechanism of the case of fat embolism, as the operation had been performed on a part relatively free from fat. It was generally noticed in such cases that the patient was bedridden, as in the present instance. He deplored the fact that patients who died under anaesthesia were removed to a distant coroner's court, where a somewhat formal post-mortem examination was made. The case under review had been more fully examined than usual, the pathologist and coroner allowing material to be removed for a more extensive examination and so preserving much valuable material which was usually lost in other cases. In the patients who had died from peripheral circulatory dilatation, death occurred from shock due to dilatation of the vessels caused by the administration of ether. He asked whether such cases occurred frequently, and whether they were due to modern methods of administration. He also inquired whether cases of pulmonary thrombosis were more frequent nowadays than formerly.

Dr. L. POWELL said that it was his practice to teach that the least amount of ether should be given which satisfied the needs of the surgeon. On common-sense principles saturation with ether for prolonged periods must be bad for the patient. Mr. PERCY SARGENT believed that death with great dilatation of the blood vessels was due either to the toxic effect of the anaesthetic or to failure of the vasomotor system. Dr. C. F. HADFIELD was accustomed to teach that the size of the pupil was relatively unimportant provided that the respiration and colour were satisfactory. He had had a case of convulsions at the end of a prolonged anaesthesia; this turned out to be due to uraemic convulsions. He called attention to the danger to the patient of removing a cancerous growth from the tongue and at the same time clearing away the glands of the neck. In his experience when the double operation was performed the patient was likely to die a few hours after operation. Dr. LANGTON HEWES described the case of an athlete who, in extremely hot weather, was under anaesthesia for two and three-quarter hours for the correction of a deformity of a joint and who exhibited the phenomenon of late ether spasm. He asked whether, when the other cases of ether spasm occurred, the weather was also hot. Dr. H. P. CHAMPTON declared himself an unrepentant advocate of deep anaesthesia. He gave all his patients atropine and morphine and was therefore unable to rely on the pupillary reaction, since, unless the anaesthesia was remarkably deep, his patients rarely showed much dilatation of the pupil.

## EVOLUTION OF LARYNGOLOGY.

At the meeting of the Section of Laryngology of the Royal Society of Medicine, on November 5th, Dr. ANDREW WYLIE, in his presidential address, gave an interesting collection of references to laryngology and rhinology, gathered from folk-lore, historical sources, and general literature. Dr. Wylie began with Peacock's *Maid Marian* and Father Prout on Dr. Tagliacotus, and passed on to Swift and Catlin's *Breath of Life*. He then considered Shakespeare, Thackeray, and Fielding, and referred to the historical half-sovereign which was impacted in the air passages of Isambard Brunel, the skill of Sir Benjamin Brodie, and the resourcefulness of the patient. He told interesting tales relating to Queen Elizabeth, James I, and Charles II. This erudite address was brought to a close with Barham's description in the *Ingoldsby Legends* of his own suffering from laryngeal cancer.

### Nerve Anastomosis and the Vocal Cords.

SIR CHARLES BALLANCE and Mr. LIONEL COLLEDGE demonstrated a cinematograph film illustrating the results of nerve anastomosis on the movements of the vocal cords. The film showed the normal movements of the vocal cords in a baboon, and the results of anastomosis between the recurrent laryngeal nerve and the vagus and between the recurrent laryngeal and the phrenic nerves. After the vagus anastomosis no return of movement was observed except on partial asphyxiation, but after anastomosis between the recurrent laryngeal and the phrenic the normal respiratory movements were seen to be restored. The last two sections of the film showed the larynx of a terrier dog and of a rhesus monkey in which an anastomosis had been performed between the phrenic and the recurrent laryngeal on both sides, and movement had been restored to both cords. The dog had regained the power of barking. The paralysis of the diaphragm had been overcome by anastomosis of the peripheral end of the phrenic nerve to the central end of the descendens noni, and the paralysis of the subhyoid and pre-laryngeal muscles by implanting the peripheral end of the descendens noni into the side of the hypoglossal.

## FRAGILITAS OSSIUM AND DEAFNESS.

At the meeting of the Section of Otology of the Royal Society of Medicine, on November 6th, Dr. DAN MCKENZIE, the new President, Dr. A. M. H. GRAY, and Mr. F. C. ORMEROD opened the session with a series of papers on diseases of the outer ear. The paper by Dr. Gray, dealing with affections of the skin of the outer ear from the standpoint of a dermatologist was especially valuable.

Mr. F. J. CLEMINSON, in a paper on deafness associated with fragilitas ossium, stated that in this condition there was a triad, the complete syndrome consisting of fragilitas ossium, blue sclerotics, and deafness of the type of otosclerosis. He displayed family trees in which 50 per cent. of the members were affected, but each element of the triad was not necessarily present in every case. He showed a section prepared by Professor Nager of Zurich from the temporal bone of such a case. This patient had been totally deaf from occlusion of both the oval windows, and the section showed areas of oto-sclerotic bone in the neighbourhood of the cochlea and oval window. Mr. Cleminson related the clinical history of a case under his own observation in which the right arm had been broken three times, the right leg once, and probably the left upper jaw. The sclerotics were greyish-blue, and a careful examination of the ears disclosed typical signs of otosclerosis, Gellé's test indicating fixation of the stapes.

Mr. G. J. JENKINS, in discussing the paper, referred to the relationship between osteitis deformans and oto-sclerosis; he made it clear that oto-sclerosis might exist histologically in the subjects of osteitis deformans without causing deafness unless the endosteum was affected. Deafness might therefore have a very late onset in the course of the disease, and appear in the form of nerve deafness instead of that commonly associated with oto-sclerosis.

Mr. J. S. FRASER described the clinical history and pathological findings in a case of congenital deafness, with mal-

# STERNAL PAIN.

formation of the bony and membranous labyrinth on both sides. This was illustrated by photographs and a series of histological sections from the temporal bones, showing the deformity of the cochlea and the rudimentary state of the semicircular canals, which scarcely existed. Mr. Fraser thought that the case was not syphilitic, the child being the last member of an otherwise healthy family of twelve, and in this opinion Dr. KERR LOVE concurred.

## STERNAL PAIN.

At a meeting of the Medical Society of London on November 8th, with the President, Sir HENRY ROLLESTON, in the chair, a discussion was held on sternal pain and its clinical significance.

Dr. JOHN PARKINSON said that the term sternal pain was a better one than precordial pain, for patients usually pointed to their sternum with some degree of accuracy. He briefly mentioned several lesions of the comparatively limited number of thoracic organs which gave rise to sternal pain, such as acute tracheitis or bronchitis, and also added that smoking, for example, might cause it. Turning to cardiac disease, the speaker pointed out that in certain serious cardiac diseases pain was a comparatively subsidiary symptom, as, for example, in acute pericarditis, or in the patient with rheumatic valvular disease who felt discomfort below the left breast, or in patients with cardiac failure who walked about with pain at the lower end of the sternum due to a congested liver. The more important type of sternal pain was that associated with certain forms of serious cardio-vascular disease. If the sternal pain was definitely related to effort it was probably of serious import. There were various degrees of sternal pain, some patients complaining of discomfort and others of a severe sense of constriction. The pain was usually mid-sternal, but might spread to the left arm or to the back, shoulders, or neck. Pain in such forms of cardiac disease was rarely absent; it was induced by exertion and disappeared when the exertion stopped. It might come on after a meal or when meeting a cold wind, and later, might follow slight exertion, such as getting into bed. Nervous patients rarely included the sternum in the area of their pain, which was usually under the left breast, but might extend down the left arm. In such cases of so-called "pseudo-angina" the ache was more constant and not definitely related to effort. Coming more precisely to the subject of angina pectoris, Dr. Parkinson indicated the great differences between authorities on its pathogenesis. The symptom of sternal pain was present in the majority of cases of this complaint; it might sometimes be localized in the left supramammary region alone, but never in the submammary region alone. Sternal pain on exertion was usually one of four varieties. Sternal pain of the heart and aorta was a common vascular disease of the heart and aorta was a common syphilitic disease of the heart and aorta was a common cause of sternal pain in a man aged 35 to 50. There might be a clear history of infection, but the Wassermann reaction would be positive. Physical examination might reveal a blowing aortic systolic, or, more characteristically, a diastolic, murmur, or the second sound might be altered. The prognosis could not ignore the risk of sudden death, but by early treatment such a variety of sternal pain might be cured. The second variety of cardiac lesion was atheroma of the aorta or coronary arteries, which was a common cause of sternal pain. The radial or brachial arteries might be thickened, but the diagnosis was usually by exclusion. The prognosis was uncertain, but in the absence of complications these patients might live for years. The third group was a subdivision of the second group, and consisted of cases of coronary thrombosis. Recent disease was rarely syphilitic, but usually atheroma. Recent work in America had thrown much light on what used to be called the "status anginosus," which was of surgical interest in that it might simulate acute abdominal conditions. The pain usually seized the patient in the night and was like that of angina, but prolonged often for hours and accompanied by symptoms of severe shock. Later there appeared signs of cardiac failure, and the pulse became fast and perhaps irregular. This disease represented a breaking up in the entity of angina pectoris, and Dr. Parkinson insisted that the position of the profession with regard to

angina pectoris was unsatisfactory. The fourth group of cases were those with high blood pressure. A small proportion of such patients complained of sternal pain, due possibly to coronary disease or to a distended aorta. Dr. Parkinson concluded by indicating the help given in the diagnosis of sternal pain by certain modern methods of investigation. Radioscopy might show the bulge of syphilitic aortitis or a dilated aorta in cases of high blood pressure. The electro-cardiograph gave information as to the state of the myocardium, since the tracing was modified or grossly abnormal in most cases of true angina.

Mr. A. J. WALTON dealt with the surgical aspect of sternal pain under several headings. Lesions of the thoracic viscera were first considered, and the speaker referred principally to those of the oesophagus. Nearly all cases of carcinoma of the oesophagus gave rise to mid-sternal pain, which was no indication of the site of the growth. The pain at first was sharp and sudden, occurring during the act of swallowing, and passing directly through to the back. Later the pain became more constant, was only slightly increased by swallowing, and was dull and aching in character. The diagnosis was generally made evident by the presence of difficulty in swallowing and the regurgitation of swallowed saliva, while it could be readily confirmed by x-ray examination after a barium meal or by the oesophagoscope. Mr. Walton then passed to sternal pain due to cardiospasm. In the common variety of this complaint, he said, patients sought treatment at about the age of 50. In one group the chief symptom was a somewhat indefinite pain, increased by the taking of food, situated in the epigastrium, and passing through to the back. In a second group regurgitation of food was the chief symptom, and diagnosis was easier. As the condition became more established towards evening; vomiting usually occurred and brought relief. Such cases might simulate cardiac disease, but careful attention to the history and x-ray investigation should make the diagnosis clear. Mr. Walton mentioned the absence of any area of referred pain in these cases of cardiospasm despite the extreme distension of the viscera which occurred. He next considered lesions of the abdominal viscera, and mentioned the frequency with which patients suffering from lesions in the upper abdomen believed that they had cardiac disease. In gastric ulcer there was usually no difficulty, but in early cases the pain might be referred to the mid-sternal region, and there might also be a band of hyperaesthesia reaching as high as the nipple on the left side. Later this disappeared, and the sharply localized area of tenderness in the mid-epigastrium cleared up the diagnosis. In the case of an ulcer which had penetrated into the pancreas pain might radiate widely up between the shoulders or to the mid-spinal region, but these areas were very distinct from those of cardiac or thoracic disease. Acute dilatation of the stomach might give rise to dyspnoea and cardiac distress, but the true nature of the complaint should be revealed by careful examination. The pain of viscerospasm might sometimes simulate cardiac pain, since it was increased by exercise and relieved by lying down; but here, again, a carefully taken history and examination of the abdomen should reveal the true nature of the trouble. Mr. Walton then dealt with lesions of the pancreas and gall bladder, since chronic inflammatory affections of these two viscera might give rise to pain which was in part referred to the mid-sternum. In cases of gall-bladder and liver disease there was the characteristic pain referred to the right shoulder, and in pancreatic cases the pain was usually in the back, referred to the left shoulder. Dr. Walton described colic ought not to give rise to any confusion with cardiac lesions. Coming lastly to local lesions, Mr. Walton mentioned how a tuberculous focus in a rib or cartilage overlying the precordium, or the presence of a bony tumour in the same situation, might at first set up localized pain mistaken for a cardiac lesion. The existence of definite tenderness on pressure and a carefully taken skiagram should generally clear up the diagnosis, but the transmitted pulsation of the heart might lead to difficulty. Certain lesions of the spinal cord, meninges, or vertebral column might give rise to hyperaesthesia over the cardiac region if the nerve roots were involved. Other signs of nerve disease were generally

present in such cases, and in tuberculous lesions the characteristic rigidity of the vertebrae should prevent any difficulty.

Sir JOHN BROADBENT stated that thirty years ago cases of angina pectoris were attributed to "fatty heart," but the modern tendency was to consider the condition as being due to coronary sclerosis. Sir James Mackenzie had taught that the pain was due to failure of contractility, and the speaker considered that there were two classes of cases: either the blood supply to the heart was affected, as in coronary disease, or the myocardium was at fault, and was leading to failure of contractility. He thought that cases of coronary disease with a positive Wassermann reaction were always fatal. Dealing with the so-called abdominal angina, the speaker said that epigastric pain coming on after exertion should not be looked upon as gastric in origin. He did not believe that syphilitic aortitis and severe aortic disease necessarily gave rise to pain.

Dr A. BLACKHALL MORISON referred to the close similarity between coronary thrombosis and acute abdominal lesions with regard to symptoms. He agreed with Dr. Parkinson's division of angina pectoris: the centre of stimulus could be in more structures than one, and he was heterodox enough to believe in "cardiac" pain. Even in cases of advanced syphilitic aortic disease pain might be absent. He thought that the pain in angina pectoris was due to "blood strokes," the sudden output of energy required by some sudden exertion. Angina pectoris might be divided into the direct and indirect types; a stimulus caused by some ulcerative changes in the aorta or coronary artery gave rise to the direct type. The myocardial type, on the other hand, might come on without exertion.

Dr. POULTON asserted that all types of dyspeptic sternal pain were produced mechanically in the oesophagus, and even the heart could produce such oesophageal pain. He described experiments in which a bag was swallowed and the contractions of the oesophagus recorded. When pain occurred there were usually large contractions shown, whereas if pain was absent there were no signs of high intra-oesophageal pressure. He thought the pain in "heartburn" was mechanical. Swallowing usually altered the pain in some way, and he showed illustrations of experiments in which the passage of a peristaltic wave abolished such pain, which was due to postural tonic contractions in the oesophagus.

Dr. J. A. RYLE said it was important to consider the site of production and cause of sternal pain. He emphasized the fact that a distended viscus was not painful, but pain occurred when a hollow viscus was trying to overcome some obstruction. The essential cause of pain was increased tension. He showed the striking analogy between the pain in intermittent claudication and in angina pectoris; the pain in angina pectoris was probably produced in the coronary arteries. "Heartburn" was a common variety of sternal pain, and it was peculiar in its burning character. It was wrong to assume that it was due to acid in the oesophagus. A similar burning pain occurred in tenesmus, and was probably due to the contraction of a hollow viscus with nothing to act against. The relief of "heartburn" by sodium bicarbonate depended on its action in causing relaxation of the cardiac sphincter.

Dr. PARKES WEBER thought that all cases of angina pectoris might be subdivided into those with gross coronary obstruction from organic change and those without. It was a mistake to regard syphilitic cases as a separate group, as those cases with gross coronary obstruction included the syphilitic. Such a differentiation was convenient for prognosis, but the difficulty was that patients in whom gross coronary obstruction had been found after death might have had no anginal pain during life.

Sir CHARLTON BRISCOE thought it was remarkable that so many different conditions produced the same type of pain. In every case one muscle could be found to be tender and in a state of tonic contraction. He showed slides to illustrate this. In one case of apical pleurisy the triangularis sterni on the right side was tender; in another case of angina pectoris this same muscle was also tender, and an attack was produced while testing this muscle. In other cases one or other of the intercostal muscles was affected, or it might be one of the scalene group.

## Rebuelos.

### THE PARASITIC PROTOZOA.

In the two volumes of *Protozoology: A Manual for Medical Men, Veterinarians, and Zoologists*,<sup>1</sup> Dr. C. M. WENYON, director of the Wellcome Bureau of Scientific Research, has presented to scientists and medical men a work on the parasitic protozoa which will rank undoubtedly as one of the standard textbooks on this subject. The book is indeed a realization of the dreams of many teachers and research workers, in that it is an encyclopaedic compilation of the present state of knowledge of the unicellular animals which are parasitic in man and the lower animals. The two volumes contain nearly sixteen hundred pages; there are 565 figures in the text, and 20 coloured plates. The arrangement of the subject-matter and the distribution of the plates have been carefully considered and the convenience of the reader everywhere studied.

Since the discovery of the first protozoon in man, attributed to the Dutch observer Leeuwenhoek in the seventeenth century, zoologists of all nationalities have slowly built up a great edifice of knowledge; medical protozoology especially received an extraordinary stimulus in the latter part of last century by the brilliant discoveries of Laveran and Ross. During the last thirty years many more remarkable discoveries in this field of parasitology have been made. Schools of tropical medicine were founded in London and in Liverpool, and Wenyon was the first to be placed in charge of the Department of Protozoology at the London School. It therefore seems fitting that it is he who has accomplished the task of writing what might be described as the romance of the unicellular animals. It can have been no easy matter to collect, condense, criticize, and present the colossal mass of literature on the subject, but the task has been most satisfactorily accomplished. It is noteworthy that in this, a first edition, there are few typographical errors. At the beginning of each volume a comprehensive classification of protozoal organisms in general is given, and a further classification of the special groups at the beginning of each separate part, so that the student can readily study the systematic position before reading the chapter on any particular subject.

The first hundred and fifty pages of vol. i serve as an introduction. They are devoted to the definition, structure, division, physiology, organelles, and syngamy of the protozoa. Then follow sections on immunity, and the production of drug-fast strains, a matter of great importance in treatment. The remainder of this volume is concerned with the amoebae and flagellates of man and the lower animals, and with an account of those coprozoic animals which may be encountered in the examination of films during diagnosis. The section on the human amoebae contains the wonderful story of the difficulties encountered by early observers, and the final triumphal emergence of definite knowledge, so necessary in diagnosis. The subject is illustrated by a useful coloured plate showing the appearance of the various intestinal cysts of man in iodine solution.

Noteworthy sections are those on the genera *Leishmania* and *Trypanosoma*, and the description of the various problems concerned with morphology and transmission. In dealing with *Leishmania*, an account is given, accompanied by a plate, of certain vegetable organisms which may be confused with true *Leishmania*. The space devoted to trypanosomiasis is rightly very large; in addition to the classification and morphology, we have parts concerned with the pathogenicity, immunity, and the curative action of drugs and serums. It is difficult to convey in a few words to prospective readers the amount of information packed into these pages regarding the trypanosomes, but the clear manner in which these have been described, accompanied by such text figures as those on pages 470, 487, and 531, to mention only a few, will appeal to all who read the work. Then there is a useful account of the group of organisms known as the *Cnidosporidia*, which are important from an economic point of view, in that they are parasites of fish,

<sup>1</sup> *Protozoology: A Manual for Medical Men, Veterinarians, and Zoologists*. In two volumes. By C. M. Wenyon, C.M.G., C.B.E., M.B., B.S., B.Sc. Lond. London: Baillière, Tindall and Cox. 1926. (Roy. 8vo, pp. xxviii + 1563; 565 figures, 20 plates. 84s. net the two volumes.)

bees, and silkworms. At the end of the volume is a study of certain parasites of undetermined position—for example, the sarcocysts common in ruminants though rarely found in man.

The second volume, approximately equal in size to the first, begins with the sporozoa, and contains chapters on the malarial parasites of man and allied pigmented parasites of animals. In addition to two coloured plates of the parasites of human malaria, the author has introduced for the sake of comparison plates of the haemosporidia of birds, malaria of monkeys, and malaria of various mammals. The morphological resemblance of the parasites of monkeys to those of human malaria is a striking feature well brought out in these plates. Into the description of the development of this parasite in the anopheline the author has introduced a series of beautiful original drawings and coloured figures, which graphically tell the story of the life cycle in the mosquito discovered by Ross over a quarter of a century ago. The coccidia, haemogregarines, and piroplasms receive adequate attention, and the last two are depicted in colour.

In the third part of this second volume a group of non-protozoal organisms, the spirochaetes, are described. Although they belong to the realm of bacteriology, they have received so far scant attention in bacteriological works, so that their inclusion here will be welcome to medical men. The fourth part deals with methods of investigation, and with the rules of nomenclature, the latter a very apt addition to such a work. In the fifth part we find what is, in our opinion, one of the most complete extant lists of the blood parasites of vertebrates and the trypanosomidae of invertebrates. Finally, the book concludes with ninety-seven pages of references, which comprise all the most important papers, monographs, and books on the study of parasitic protozoa.

The book is, we believe, the best written on the subject in any language; it is certainly a very fine piece of work and a credit to the English school. It marks a great advance in the correlation of our knowledge of the protozoa. No medical man domiciled in the tropics or interested in the problems arising from diseases of protozoal origin should be without a copy.

#### ACUTE PANCREATITIS.

M. P. Brocq, inspired by Professor P. DELBET, started in 1913 to gather material for his monograph *Les pancréatites aiguës chirurgicales*,<sup>2</sup> which is based on 340 collected cases (20 now published for the first time), on his numerous experiments on dogs, and on a thorough survey of the literature. Although this abdominal catastrophe usually comes as a bolt from the blue, he shows reason to believe that it occurs in a pancreas already showing morbid changes, and admits that for this reason the results obtained by the experimental production of acute pancreatitis in dogs with normal pancreases are not absolutely comparable in every respect. Obesity, overeating, gastrointestinal disorders, and especially gall stones (in two-thirds of the cases), are the most frequent antecedents. The different forms of acute pancreatitis are all derived from the same fundamental lesion—namely, necrosis, usually partial, of the gland; haemorrhage is extremely common, but fat necrosis takes more time to appear and so may not be seen in fulminating cases.

A noticeable conclusion is that the initial necrosis is aseptic and due to the digestive action of trypsin when the protrypsin has been activated by cellular kinases. Of the two hypotheses as to its causation, that which ascribes it to vascular lesions, such as thrombosis, embolism, and chronic arteritis, is shown by the author's experiments to be less probable than that which refers it to damage inflicted by way of the excretory ducts of the gland. The problem what are the factors activating the pro-ferment is discussed in considerable detail, and illustrated by the results of many experiments. The influence of bile retrojected into Wirsung's duct as the result of obstruction of the orifice of the biliary papilla is considered; only eight

cases (of which one is published here for the first time with an illustration) of calculus blocking the tip of the biliary papilla are on record. But though the efficacy of bile in the pancreatic ducts to activate protrypsin is fully admitted, and Archibald and Brown's explanation that reflex spasm of Oddi's sphincter may cause reflux of bile into the pancreas is mentioned, the action of bile is regarded as one only of the possible causes of activation of protrypsin. The clinical and pathological features of aseptic forms of acute haemorrhagic, oedematous, sub-acute, encysted (pancreatic haematocoele), and attenuated pancreatitis are described with judicious use of statistics and personal cases. Suppuration and gangrenous pancreatitis, due to superadded infection, are dealt with separately. The sections on diagnosis, clinical and laboratory, and on treatment are full, and the usefulness of this valuable book of reference is increased by a good bibliography.

#### A HANDBOOK OF FORENSIC MEDICINE.

The place which Hofmann's textbook of forensic medicine<sup>3</sup> has attained in the literature of the subject is shown by the appearance of the eleventh edition in two large volumes comprising 1,234 closely printed pages.

The original book was recognized at once as a work of outstanding merit which placed forensic medicine on a more scientific basis than it had previously occupied. The tenth, and now the eleventh edition, have, in the able hands of Professor HABERDA, fully maintained the reputation of this great work. Forensic medicine has advanced during recent years, like other sciences, with rapid strides, and no more capable editor could have been employed. Indeed, Professor Haberdar has partly rewritten and greatly amplified the original. It is a complete textbook in every sense of the term, and the psychiatric part is ably dealt with by Professor Wagner-Jauregg.

Not the least valuable aspect of the present volumes is the very complete references to literature, brought down to the middle of 1926. Many new and striking illustrations have been introduced which assist the elucidation of the text.

It is a trite but eminently true remark that no one who professes this subject can afford to be without this edition of what we confidently affirm to be the most complete and accurate treatise on forensic medicine.

HARVEY LITTLEJOHN.

#### ECZEMA.

Dr. G. A. Rost has produced a useful textbook of dermatology.<sup>4</sup> Without claiming that he has exhausted the subject, he has dealt with all questions which concern the general practitioner, for whom his volume is primarily intended. He has rightly devoted most space to, and laid most emphasis upon, those conditions which are the more commonly met with, and has only briefly referred to the rarer affections of the skin. In his arrangement of chapters he has adopted an etiological classification of dermatoses. Some day, let us hope, it will be possible to do this with precision, but at the present moment we are regrettably in the dark as to the causation of so many of the pathological conditions of the skin, that to try to use the tempting and apparently logical method of etiological classification is to follow a scientific will-o'-the-wisp and only lands one in a tangle of contradictions. For practical purposes it still seems preferable, after disposing of the conditions definitely known to be due to external causes, to fall back on a morphological arrangement. Apart from this objection to his scheme of classification we have nothing but praise, for Dr. Rost is very practical and fully up to date. The matter which at present is chiefly agitating the dermatological world is the question of eczema—what is meant by the word itself and what conditions may fairly be included under the title. In the present book a large number of conditions which might

<sup>2</sup> *Les pancréatites aiguës chirurgicales*. Par Pierre Brocq. Annales de la Clinique chirurgicale du Professeur Pierre Delbet. Paris: Masson et Cie. 1926. (Roy. 8vo, pp. 188; 3 figures, one coloured. 4s. 2d.)

<sup>3</sup> *Hofmann's Lehrbuch der Gerichtlichen Medizin*. Edited by Dr. Albin Haberdar. Professor of Forensic Medicine, University of Vienna. Eleventh edition. Vienna: U. J. Leschnitzer. 1926. (Roy. 8vo, pp. 1,234; 104 figures, one coloured. 12s. 6d.)

<sup>4</sup> *Hautkrankheiten*. By Dr. G. A. Rost. Leipzig: J. F. Bergmann. 1926. (Med. Bro. pp. x + 405; 104 figures. 8.50 M.)

possibly be included under this head are described as due to the "status exsudativus." The author is evidently a devoted follower of Czerny, to whom we owe this conception. It cannot yet be said that this statement of the position has been substantiated, but a fair discussion such as is here given is well worthy of the attention of dermatologists. The book is well printed, easy to handle, and the illustrations, both coloured and in monochrome, good and clear. Dr. Rost's textbook should by no means be without honour in his own country, but for the British student and practitioner there are several works produced at home which will serve his purpose equally well.

Eczema has been described as the most important subject in the whole of dermatology, and Dr. S. JESSNER, who is the author of a number of monographs on dermatological subjects, primarily intended for the general practitioner, has dealt very fully with it in a small book<sup>5</sup> on its diagnosis and treatment. Only a few pages are devoted to the nature and etiology of the eczematous reaction, rather more to the differential diagnosis of the condition, and the remainder, about two-thirds of the whole, to its treatment. He considers in some detail the internal treatment, including dietetics and spa therapy. Like most of us, he has not a very high opinion of the efficacy of such measures, and is quite free from the fads dear to so many German writers. He rightly lays the greatest stress on local treatment, and after giving general directions goes in detail into the modifications advisable in different types of the condition, and also as it occurs on differing parts of the cutaneous surface. His teaching is quite sound, but it is interesting to note the variations of fashion in therapeutics between this country and Germany. Perhaps they are greater now than they were before the war, when every German drug and unguent was eagerly snapped up by the medical public. The fashion has now swung over to favour the French pharmacist, hardly, however, to the same degree. One of the commonest German remedies, very seldom used here, is solution of aluminium acetate, another is tumenol (a tar preparation), another is mitin (a base for ointments). Dr. Jessner does not forget to mention the use in treatment of various forms of radiant energy, such as the Roentgen rays, which he finds extremely useful, and the various forms of artificial sunlight, which he considers to have only very limited application in the treatment of eczema; in fact, he only recommends it in scrofulous eczema, a variety of the condition which in this country is hardly recognized. This little book, now in its third edition, can be recommended to any practitioner desiring guidance in dealing with eczema, and even an experienced dermatologist may pick up some tips from it.

### NOTES ON BOOKS.

Dr. A. C. JORDAN has published a second edition of his monograph on *Chronic Intestinal Stasis (Arbutnot Lane's Disease): A Radiological Study*,<sup>6</sup> the first edition (1923) of which was reviewed in our columns (1924, i, 154). The work is much the same in substance and size as before; the preface tells us that the author has resisted the suggestion that the scope of the work should be enlarged so as to provide a complete treatise on the radiology of the digestive system, but that small additions have been made to the chapters on the pelvic colon, appendix, and gall bladder. In the case of the gall bladder there are seven lines on cholecystography and three new skiagrams, none of which, however, show the results of the new tetraiodo method. The remaining information on gall stones occupies six lines, and of them the three lines, "Gall stones are not very often seen in the x-ray picture, for cholesterol is perfectly transparent, and a gall stone does not produce a shadow until it has existed long enough (years) to have become encrusted with lime salts," might be qualified or expanded with advantage. But in fairness to the author it should be borne in mind that this subject is rather outside the restricted field of chronic intestinal stasis. Criticism may also be excited by the statement that "a healthy appendix is never attacked by acute inflammation, and it does not become diseased

unless its environment is unhealthy"; for, though no doubt acute inflammation often supervenes on old, it is difficult to bring forward evidence that acute infection does not fall on a previously normal appendix. As before, the get-up of the volume is good and the radiograms generally are clear.

The scientific papers which have been contributed to medical journals during the years 1923-25 by the staff of the Walter and Eliza Hall Institute of Research in Pathology and Medicine, Melbourne, have been bound together into a single volume.<sup>7</sup> We notice that the staff of the institute has given a great deal of attention to hydatid disease, and seven of the twenty-two articles deal with it. The diagnosis of this disease by clinical and laboratory methods has been the chief problem studied. The other papers deal with a great variety of subjects, ranging from tuberculosis to cancer. Most of them are reprinted from the *Medical Journal of Australia*, but one or two have appeared in the *Journal of Pathology and Bacteriology*. Dr. C. H. KELLAWAY, who was recently attached to the Medical Unit at University College Hospital, London, is now the director of this institute for research.

In the form of a novel entitled *The Factory King's* Dr. NORMAN PORRITT, who was recently awarded the Hastings Prize, has given us a vivid and poignant account of factory life in the middle of the nineteenth century, when Richard Oastler, whom he appropriately calls "the Danton of the factory movement," made it his aim to improve the lot of the factory worker. The avariciousness of the mill owner, who drove men into unemployment and drink by the substitution of cheap labour by women and children, and the brutality of the factory overseer, are drawn in lurid colours, but Dr. Porritt assures us in the preface that he has not drawn on his imagination for the facts, but has taken his description from contemporary records and writings.

In *Man not a Machine: A Study of the Finalistic Aspects of Life*<sup>8</sup> Professor EUGENIO RIGNANO of Milan brings forward many arguments to refute the materialistic view that the body is a purely physico-chemical apparatus on the analogy of the growth of a crystal, and contends for the existence of a form of energy peculiar to life. Examples of pre-established and of new adaptations with a purposive object are marshalled against the mechanistic explanation of life, and in the last chapter the social purposiveness of justice and morality is brought forward in support of his thesis.

<sup>1</sup> *The Walter and Eliza Hall Institute of Research in Pathology and Medicine*. Vol. II, 1923-25. C. H. Kellaway, M.D., ed. (Demy 4to; illustrated.) Porritt. London: Jonathan Cape 1926.

<sup>2</sup> *Man not a Machine: A Study of the Finalistic Aspects of Life*. By Eugenio Rignano, Professor in the University of Milan: With a Foreword by Professor Hans Driesch. Psyche Miniatures. London: Regan-Paul, Trench, Trubner and Co., Ltd. 1926. (Pott 8vo, pp. 77. 2s. 6d. net.)

### PREPARATIONS AND APPLIANCES.

*Preparations of the State Serotherapeutic Institute, Vienna.*

We have received from the State Serotherapeutic Institute, Vienna, preparations put up in a convenient form for performing certain well known clinical tests.

They include "dermotubin" or skin tuberculin (Loewenstein). This is a concentrated glycerin broth culture of the tubercle bacillus. A drop is placed on the skin and rubbed in for a minute; a positive reaction consists in the appearance of nodules after one or two days. This is obviously a very convenient and safe method of carrying out tuberculin tests, and it has been subjected to extensive clinical trials. The safety of the test is proved by the fact that it was applied to 11,000 Viennese school children without any undesirable effects being observed. (Loewenstein: *Wiener klin. Woch.*, 1925, No. 5.) Extensive reliability tests have also been performed, and the tuberculin ointment test has been found to agree with the Pirquet injection test in 90 per cent. of cases. (Kundratitz: *Zeit. f. Tuberculose*, 42, 222, 1925.) The method seems therefore to provide a very safe and easy technique for applying the tuberculin test.

Another preparation, "haemotest," consists of a small box containing the simple apparatus necessary for determining the blood group to which any patient or prospective blood donor belongs. The essential parts of the apparatus are tubes containing serum from persons belonging to blood groups 2 and 3 respectively. With this apparatus the blood group to which any person belongs can be determined in five minutes. The apparatus is arranged in very convenient form, and a full description of the technique is provided. The letterpress appears, however, to be a literal translation of German directions, and it would be clearer if the English were improved.

<sup>5</sup> *Diagnosis and Therapie des Ekzems*. By Dr. S. Jessner. Third edition. Leipzig: C. Kalyeb. 1925. (Pott 8vo, pp. 173. M.6.30.)

<sup>6</sup> *Chronic Intestinal Stasis (Arbutnot Lane's Disease): A Radiological Study*. By A. C. Jordan, M.D. Camb., M.R.C.P. Lond. Second edition. Oxford Medical Publications. London: Humphrey Milford, Oxford University Press. 1925. (Cr. 4to, pp. xv + 250; 315 figures. 21s. net.)

THE VIRUS THEORY OF CANCER.

British Medical Journal.

SATURDAY, NOVEMBER 13TH, 1926.

THE VIRUS THEORY OF CANCER.

THE hypotheses put forward to explain the genesis of cancer have been legion, but for many years past there have been two that, owing to the numbers of their respective supporters and their inherent probability or plausibility, command pride of place. There is the irritation theory and there is the parasitic theory. According to the former, cancer is the result of chronic irritation: cells subjected to long-continued stimulation by some definite, or more often indefinite, means at last acquire a new property of limitless and destructive proliferation. It may be that the chief exponents of the doctrine nowadays would state it in more precise terms, but it is almost a necessary corollary that "cancer" is to them merely a generic word. According to the parasitic theory, some *contagium vivum*—protozoal, bacterial, or ultra-microscopic organism—gains access to cells and causes them to proliferate, itself multiplying within these cells and keeping up the constant division. In support of the irritation theory might undoubtedly be cited numerous examples of cancers in man where definite irritating substances had been present at their inception; and, above all, the experimental work of recent years in the production of tumours in animals by the use of various substances seemed to place the theory on a sound basis. It is one of the weaknesses of this theory that, in man at least, so very few of the subjects exposed actually develop cancerous growths, and it has been held that the irritants merely prepare the soil for the intervention of some other cause. Further, it has to be admitted that in the great majority of cases of cancer it is difficult to trace any definite sort of irritation. The ceaseless pursuit of a germ, on the other hand, had yielded no result. Some hoped that in process of time new staining methods would reveal it, just as Giemsa's stain revealed the organism of syphilis; some thought that novel cultural methods would be devised so that it could be obtained in a free condition; and some fondly believed that an ultra-microscopic parasite would be isolated from cancers. Cancer, according to them, would be a specific disease. The schools were sharply divided, and no common ground could be found.

In these circumstances the theory put forward last year by Dr. W. E. Gye attracted world-wide attention. It attempted to reconcile the two conflicting views without conceding to either all that their adherents had claimed, and to not a few it seemed as though the central problem in cancer had at last been solved. In the Lloyd Roberts Memorial Lecture, which we publish at page 865 this week, Dr. Gye traces the development over many years of experimental research that has cleared the ground for modern investigations, and he states again persuasively the original experiments he has performed and the conclusions to which these have led him. Briefly expressed, his theory is that cancer is a specific disease caused by the combined operation of an ultra-microscopic organism, or virus, and an

accessory chemical substance which determines the special characters of the resulting cancer. It would seem as though the virus were omnipresent but incapable of producing its effect until the chemical substance has been elaborated. Hitherto this accessory factor has only been obtained from pre-existing malignant tumours, but it has been suggested that it may result in the body from the action of irritants of various kinds. The experiments on which this theory is based are again set forth. It was known that a peculiar lesion in fowls, considered by Rous, its discoverer, and by many others to be a spindle-cell sarcoma, could be transferred from one fowl to another by the filtered and presumably cell-free juice. By heat and by certain chemicals the activity of this extract could be destroyed, but Dr. Gye gives reason for believing that the extract contains two different factors which may be separated. By treatment of the filtrate with chloroform or acriflavine he suppresses one of these (the virus) and leaves the other (the chemical factor) unimpaired. Then by cultivating a portion of the fowl tumour by special technique he obtains the "virus" alone. When this cultivated "virus" is added to the "chemical factor" the characteristic Rous sarcoma is obtained on injection into suitable fowls. Neither of the ingredients alone produces the condition. Does this Rous sarcoma stand by itself, something unique, quite unrelated in etiology to other tumours? So it had been regarded. All attempts to obtain active cell-free filtrates in mammalian tumours had failed, nor could Dr. Gye repeat successfully with them the method he had adopted in the case of the fowl tumour. However, by cultivating certain mammalian cancers in his special medium he obtained something which, when combined with the Rous "chemical factor" and injected into chickens, produced the fowl sarcoma. In other words, he successfully substituted for the Rous virus some similar, if not identical, "virus."

The proof, therefore, that mammalian cancers contain a "virus" is indirect, and it is only by inference, and not by experiment, that it is permissible to conclude that they contain an "accessory chemical factor." Nevertheless, the experimentation so far as it has gone is very attractive, and the deductions are ingenious. It may be remembered that in the week following the appearance of Dr. Gye's original communication we published an article by Dr. Archibald Leitch,<sup>1</sup> which, though highly appreciative, yet pointed out certain weaknesses in the argument and cast doubts on the claim that the chloroform treatment had quite destroyed the activity of the filtrate; and in the same issue Dr. Twort, in our correspondence columns, suggested that other substances besides malignant tissue extracts might restore the activity of the chloroformed filtrate. If it could be shown that the active agent of the Rous sarcoma was not destroyed by the chloroform, then the whole theory would fall to the ground. Since that time a considerable amount of critical work seems to have been performed in this country and abroad which tends to support these early criticisms. Murphy of the Rockefeller Institute and Flu de Leyden, in particular, have been able to restore the activity of the chloroform-treated extracts by "cultures" of normal tissues, although Dr. Gye in his own experiments has not succeeded in so doing. At the present moment, therefore, it would appear that Dr. Gye's attractive theory, so widely broadcast less than eighteen months ago and so authoritatively sponsored, is being subjected to an artillery fire that may destroy it.

<sup>1</sup> BRITISH MEDICAL JOURNAL, July 25th, 1925, p. 174.

## POPULATION AND PESSIMISM.

EACH year there is a net increase in the population of human beings and in the number of books on the growth of human population. Dr. J. Shirley Sweeney's spiritual child, an essay entitled *The Natural Increase of Mankind*,<sup>1</sup> saw the light in the Johns Hopkins School of Hygiene; Professor Raymond Pearl was the obstetrician and Professor William Welch is the godfather, and the child is not unworthy of such eminent protectors.

Dr. Sweeney has made a painstaking study of the changes in the "vital index"—as Professor Pearl terms the percentage ratio of annual births to annual deaths—in practically every country which furnishes any statistics. He has found that nearly all the countries studied possess high mean indices—that is, that population is almost everywhere increasing—although the magnitude of the index and the slope of the line indicating its secular trend are negatively correlated. Further, a study of the belligerent nations showed that "the birth-death ratios, although extraordinarily lowered during the war and influenzal years, resumed their pre-war and pre-influenzal levels within two years' time." It was therefore held that "war and pestilence serve only to cause a temporary disruption in the chief factors of population growth." It was held, furthermore, that "population growth was shown to be a steady, uniform, and persistent phenomenon."

Different statisticians might prefer slightly different methods of presenting the facts—we have never been able to convince ourselves that the ratio of births to deaths is a better index than the more frequently employed rate of natural increase—but all would agree that these are trifles, and that Dr. Sweeney has effectively and succinctly presented the essential facts. What is the conclusion to which they lead? They lead Dr. Sweeney to a gloomy one. He thinks, indeed, that absolute overpopulation, in the crude sense of the term—that is, in the sense that human population will reach a point at which there is literally not sufficient food to maintain it in existence—will never occur as a world phenomenon; but that there will be a *relative* overpopulation, evoking some of the positive checks of Malthus, such as wars. The only remedy he can see is in deliberate limitation, but, in preference to Mr. Harold Cox's suggestion of a "league of low birth rate" among European populations, he advocates a league of "stationary populations." Whether this would really be more acceptable, as he thinks, is doubtful. It is true that there is a differential racial fertility, and it is true that "a low birth rate is a relative term, whereas a stationary population avoids the issue of discrimination in the strictest sense." But since, apart from migration (and, of course, from changes in marriage rate and age constitution), the only way in which a population now increasing can be kept stationary is by increasing the death rate if the birth rate is maintained—and nobody would advocate that—Dr. Sweeney's practical proposal is not really different from Mr. Cox's. But, again, the point is hardly more than a verbalism if Dr. Sweeney is right in being without hope that what he has said "will make the slightest impression upon things as they now are. All that is hoped is that perhaps a few minds, heretofore closed to the consideration of the matters we have brought up, may be slightly opened, and that later discussions of the population question may experience

somewhat less resistance." This conclusion we take to be that of most sensible men, but if so, how is it that we are not all profoundly depressed by the prospect before the world—indeed, before our own nation? The population of England and Wales is certainly increasing. Dr. Major Greenwood's estimate<sup>2</sup> that by 1931 there will be three and by 1941 five millions more alive in England and Wales than in 1921 may be too pessimistic (or too optimistic, according to the point of view); but no serious prophet has budgeted for a decrease, and, if there be any truth in what masters and men are now saying, at least one industry is already employing a quarter of a million more men than economic "facts" justify, while no other industry is exactly clamouring for a quarter of a million recruits. We must, then, choose between a reduction of natural increase (whether by decrease of births or increase of deaths) and a lowering of the standard of life.

Why are we not alarmed? There are, perhaps, two reasons. One is summed up in the phrase, "It will last my time." Those who have to face the worst horrors of a war are seldom those who experienced the utmost rigours of its predecessor. And one may take that point of view without being purely selfish. How many of us have succeeded in passing on our experience of the common facts of life to our own children, in enabling our sons to avoid making precisely the mistakes we made at their age? If we cannot do this we shall certainly fail to convey our experiences of the uncommon events of 1914-18 to those born in or after 1900—that is, to those who would now form a majority, and will soon form a large majority, of the rank and file should Europe be so unfortunate as to become involved in another war. There is another factor: the religious man calls it the providence of God, the psychologist the unconscious mind. The apparently inevitable conclusion of logic has in economics, in politics, and even in medicine, so often been disproved by the event that, when the problem is a complex one, we distrust logical conclusions and assume that things will neither be so good nor so bad as reasoning would have us expect.

There is a great variety of reasons why the state of the people of England should be, on the average, much worse now than in 1914. Plenty of people assure us that it is much worse, and will shortly be worse still. Yet any one of the time-honoured tests—infantile mortality, mortality from tuberculosis, prevalence of the diseases associated with filth and misery—leads to the conclusion that the people are not worse but better off than before the war. Of course, these tests are not conclusive; we may be entering upon a period of increasing misery, we may even be upon the brink of some great calamity. But this at least is true, that those who, like Dr. Sweeney, have no belief in the efficacy of argument to influence the reproductive habits of mankind, even those who pay not the least attention to the jeremiads of the eugenicists and care not a jot for the survival of the unfit, are often neither ignorant nor selfish, but merely humble-minded. Perhaps *tout le monde* is really wiser than any individual, even a distinguished economist, a eugenicist, or a statesman.

THE Nobel Prize of the value of 37,000 dollars has been awarded to Dr. J. Fibiger, professor of morbid anatomy at the Copenhagen Faculty of Medicine, whose experimental production of carcinoma of the stomach in rats by a nematode is a milestone in the history of the study of cancer.

# STUDY OF MEDICAL HISTORY.

ARRANGEMENTS are being made for the formation of a History of Medicine Section at the forthcoming meeting of the British Medical Association at Edinburgh in July, 1927. A great deal of interest has been taken and research carried out on this department of medicine in the universities of the Continent, and at the present time few of the larger medical schools in America are without historical libraries. It is appropriate that the first meeting of a Section on History of Medicine should be held at Edinburgh, both because the 1927 meeting is, in a sense, historical, being connected with the celebration of the centenary of Lord Lister's birth, and still more because Edinburgh University was the first medical school in this country to recognize the importance to the practitioner of a certain amount of acquaintance with the history of his calling, by deciding to establish a lectureship on history of medicine in 1908. The course is a voluntary one, and has been held continuously every winter session since the institution of the lectureship, with the exception of four years during the war, and has been attended each year by from sixty to ninety students. The syllabus for 1926-27 shows that the course consists of twenty lectures, comprising an outline of medical history, beginning with Egyptian medicine and passing through the development of medicine among the Greeks and Romans. Hippocrates and Galen are dealt with in a biographical and critical sense, while accounts of Arabian medicine and of the medical aspects and politico-social effects of the mediaeval epidemics give pictures of medicine in the Middle Ages. The history of hospitals, including the activities of the Knights of St. John and of the foundations made by Pope Innocent III and St. Louis in the thirteenth century, together with an account of the rise of the universities and the formation of the medical guilds, outlines the Renaissance as it affected medicine. Other lectures then deal with the revival of the experimental method in connexion with medicine and its results. The early labours of Bacon and Harvey, followed by those of the group who, after the Civil War, were concerned in the foundation of the Royal Society, show the earlier stages of this movement; and the great light thrown upon bodily processes by the discovery of the microscope is demonstrated in connexion with its adoption by Malpighi, Leeuwenhoek, and others. The development of physiology is continued by an outline of the early work done and suggestions made by Van Helmont, Sylvius, Reaumur, Beaumont, and others, who turned their attention to the question of digestion and secretion, which culminated in the important researches of Claude Bernard, Karl Ludwig, and their present-day successors. The development of our knowledge of respiration, successively built up by Boyle, Hooke, Mayow, Black, Priestley, and Lavoisier, forms the subject of another lecture; while still another treats of concurrent developments of the knowledge of nervous phenomena through the researches of Willis, Haller, Bell, Magendie, Broca, and others. The later development of pathology and the progress of clinical medicine in the eighteenth and nineteenth centuries, as it took place in the various schools of France, Britain, and Germany, and the development of surgery in the eighteenth and nineteenth centuries, are also outlined. The course for the present academic year appropriately concludes with two lectures on the origin and development of the Edinburgh medical school and on the life and work of Lister.

## MILK REGULATIONS IN COPENHAGEN.

THE milk supply of Copenhagen is derived from some 3,400 farms in Zealand and elsewhere, with a total stock of about 54,000 cows. The daily consignment of milk to the city, exclusive of cream, buttermilk, and skimmed milk, is about 60,000 gallons, some 3,000 gallons of which are

described as milk for infants and 700 gallons as Jersey milk. The regulations for the sale of milk in Copenhagen, which are quoted in a recent publication by the League of Nations, are administered by the local health committee. They deal with all milk sold in the city from its production on the farm to its place of distribution. No business for the sale of milk in Copenhagen may be conducted without notice given to the sanitary authority. "Whole milk," according to the regulations, must not contain less than 3.25 per cent. of milk fat. The cows providing it must be inspected monthly by a veterinary surgeon, who on each occasion must carry out a minute examination of the udder, testing milk from each teat. The veterinary surgeon in his certificate must indicate whether the rules laid down by the health committee for owners of herds supplying whole milk to Copenhagen are being observed. These rules are concerned with cleanliness and other points. All milk offered for sale as milk without a specific designation is held to be offered for sale as whole milk. "Milk for infants" likewise must not contain less than 3.25 per cent. of milk fat. The herd providing it must be tested with tuberculin once a year, and animals which have passed the test ear-marked. Reactors must be isolated and disposed of. Any animal added to a herd must have passed the tuberculin test. Every animal in the herd must be inspected fortnightly by a veterinary surgeon, who must certify as regards observation of the rules applying to producers of milk for infants. The use of milking machines is forbidden. The milk, after milking, must be cooled at once to 8° C. and kept in a cold place till it reaches the consumer. It must be sold only in properly closed bottles of tinted glass, which must be sterilized or carefully cleansed and duly labelled. The sale of "pasteurized milk" is prohibited unless so described. Pasteurization is defined as heating to at least 85° C. and cooling immediately thereafter to 10° C. Milk heated in any other way may not be described as pasteurized, and may not be sold at all unless approved by the health committee. Repasteurization is forbidden. Containers must be sterilized or carefully cleansed. Bottles, if used, must be of tinted glass. "Mixed milk for infants" may be sold in bottles, mixed with boiled water and containing sugar, provided the exact composition of the mixture is stated on a label affixed. "Jersey milk" may be drawn from Jersey cows only, and must contain not less than 4.75 per cent. of milk fat. The regulations also include provisions as to sick cows and infective persons, and as to milkshops in Copenhagen, their cleanliness and lime-washing, their relation to sleeping-rooms and other goods which may be sold on the same premises, and the supply of water-spitoons of a serviceable type. Of the milks named under the Copenhagen regulations, "milk for infants" is apparently the equivalent in Copenhagen of the milk designated "certified" in this country, except that on the Danish plan the herd is inspected more often but tested with tuberculin less often, while the fat requirement differs from the usages here, and no bacterial standards are laid down. "Whole milk" may be regarded as broadly corresponding to a Grade A milk in this country, except as regards the fat content and the absence of bacterial standards. It has, however, a wider range. Grade A conditions here can only be applied to persons desiring to employ the designation "Grade A." Whole-milk conditions in Copenhagen are, on the other hand, not only applicable to vendors of whole milk by that title, but are imposed also upon vendors of milk *simpliciter*, since all milk not specifically otherwise described is held to be whole milk. The useful effect of this interpretation would appear to be that all unclassified fresh milk sold in Copenhagen is produced under the condition of a monthly inspection of the herds concerned. For "pasteurized milk" in Copenhagen no bacterial standard is laid down. The general powers contained in the Copenhagen regulations

as to infection, cleanliness, management, notices to sanitary authorities, and the like, are provided in this country either under statute or by rules and regulations. The supply of water-spittoons in milkshops, however, is not exacted here. Alike in their points of agreement and difference, the Copenhagen sale of milk regulations offer an interesting comparison with the methods current in this country for securing the great object aimed at in both cases—the purity of the milk supply.

#### "SOME HEART ONCE PREGNANT WITH CELESTIAL FIRE."

IN *A Nineteenth Century Teacher* Mrs. Liveing gives us a biography of her uncle, John Henry Bridges, sometime Fellow of Oriol College, Oxford, and medical inspector to the Local Government Board. Her story is full of pathos; for John Henry Bridges was a brilliant Oxford man who became an apostle of a lost cause. To those of us who remember in our youth the warfare of the Positivists with the Church on the one hand and with Professor Huxley on the other, a book about a disciple of Comte is bound to have an old-world flavour. It is easy to suggest that Positivist philosophy left its mark on English thought and life, and that the little band of men led by Frederic Harrison anticipated the trend of much modern action; but the fact remains that the philosophy made little appeal in the nineteenth century, and in the twentieth it has practically ceased to exist. But for his enthusiasm for the religion of humanity Bridges might have been a great historian, a great sociologist, a great doctor, or even perhaps a great administrator. As it was, Mrs. Liveing is forced to confess that the man "has not been forgotten, he has never been discovered." Bridges was a man of catholic interests, as his writings show. His *France under Richelieu and Colbert* made S. R. Gardiner deplore the sacrifice of a great historian to the Local Government Board. His work for improved Poor Law hospitals and for the control of ophthalmia and small-pox might have made the Local Government Board deplore his absorption in international politics. His views on dominion home rule, on China, and on Ireland, though really a part of his religious philosophy, might have made the internationalist and the League of Nations enthusiast of to-day jealous of his devotion to Positivism. It was this versatility and intense interest in many sides of life which caused the failure of Bridges to attain the eminence which his brilliance and accomplishments deserved. Yet who shall say that he was in any way less happy a man for that? His love of poetry, his powers of conversation, the devotion of his relatives and friends, and the knowledge of much sound work accomplished—surely all these things must have given peace and contentment to his mind. And added to this he had the satisfaction of faith in a religion of which, in England, he was in truth the spiritual head. Mrs. Liveing's study is a pleasing tribute to the memory of a great and noble, if little known, character.

#### SMALL-POX AND COMMERCE.

Dr. H. E. YORNG, provincial health officer of British Columbia, in the annual report of his department for the year ended June 30th, 1926, discusses the recent prevalence of small-pox in and around Vancouver, the chief commercial city of the province.<sup>2</sup> In the face of very active propaganda in Vancouver and in the capital city of Victoria, he and his colleagues managed to secure vaccina-

tion of 60 per cent. of the school children. This, with the large number of people who had been vaccinated during the war, and also those who realized the value of vaccination, placed the Provincial Board of Health in a much better position, with the result that there were only 98 cases in the period under review, compared with 1,014 in the previous year. In 1925 the United States insisted that all persons travelling south from Vancouver must show evidence of recent vaccination. The serious effects of this prohibition were not at first appreciated by the business world of the city. But its removal brought about a remarkable change in public opinion. "They realized in terms of money what the ban had meant, and they went to the other extreme and asked that the Provincial Board of Health would enact regulations that would prevent the employment of anybody unless they were vaccinated." Although this was asking too much, the Board has already gone some way in the right direction. Before the ban was raised it had urged upon the large mining interests in British Columbia the need for insisting that their employees should be vaccinated, and met with a ready and favourable response. Following this it approached the officials of the Canadian Pacific Railway, pointing out that their employees were probably more exposed than any others to small-pox, because they were in constant touch with the public and in greater danger of carrying the disease. The C.P.R. finally agreed to instruct its heads of departments that applicants for any employment which brings them into direct contact with the travelling public must either undergo vaccination or produce a certificate of successful vaccination within the preceding twelve months. Encouraged by this success, the Board persuaded the manager of Western Lines of the Canadian National Railway to take corresponding action. "We think," writes Dr. Young, "that this has been one of the greatest advances that we have made along the lines of preventing disease. The fact that these two large companies, the largest employers of labour in Canada, have made this ruling will be an argument hard to answer when other employers are approached."

#### INTERNATIONAL TUBERCULOSIS STATISTICS.

THE Health Organization of the League of Nations appears to have set Dr. S. Rosenfeld of Vienna a Sisyphean task in the preparation of a report on an international investigation of tuberculosis statistics. No sooner does Dr. Rosenfeld roll his ponderous statistical stone up the hill on a set of rails made in Germany, than down it comes again at the impetus of a fallacy manufactured in England or Japan. Dr. Rosenfeld thinks that international statistics of tuberculosis mortality, though still far from exact, do not prevent us from following the variations in mortality provided we take the precautions he advises. He hopes that the statistics may give a solid basis for researches tending to the discovery, not only of the causes of variation in tuberculosis mortality, but also of the causes of this mortality. The investigations would be much less difficult if all countries adopted a standard nomenclature, a universal system of death certification, and proper classification, and possessed a properly educated medical profession. At present in many countries deaths are often certified by laymen; and although Dr. Rosenfeld says that "the layman is generally able to recognize pulmonary tuberculosis," and that "tuberculosis is not often overlooked, as the diagnosis is generally easy," we feel that these statements require some qualification. Apart from the difficulties that occur in countries where non-medical persons give certificates of death, trouble arises on the certificates of medical men. Why, he asks, is the death rate in England from acute and chronic bronchitis extremely high, and the tuberculosis mortality extremely low?

<sup>1</sup> *A Nineteenth Century Teacher: John Henry Bridges, M.B., F.R.C.P.* By his Niece, Susan Liveing. With a preface by Professor L. T. Hobhouse, and an introduction by Professor Patrick Geddes. London: George Paul, Trench, Trubner and Co., Ltd. 1926. (Cr. 8vo, pp. x + 262; 1 portrait, 10s. 6d. net.)  
<sup>2</sup> See BRITISH MEDICAL JOURNAL, August 1st, 1925, p. 229.

Dr. Rosenfeld's answer is that there must be a transfer, intentional or not, from one group to another. He urges that in reporting meningitis, pleurisy, pericarditis, peritonitis, etc., the physician should be required to add the words "tuberculous" or "non-tuberculous." Dr. Rosenfeld is of opinion that the establishment of State insurance systems has introduced a fallacy into statistics, at all events in countries where notification of the cause of death is not confidential, as it is in Switzerland. He believes that out of consideration for the memory of the deceased, or of the susceptibilities of his family, or in order not to admit an error of diagnosis, the physician certifies the cause of death of an insured person as "chronic bronchitis" instead of tuberculosis. Dr. Rosenfeld dwells also on difficulties due to the interpretation of terms in death certificates. According to him, in England the words "primary" and "secondary" on certificates of death indicate the relative importance of the diseases, whilst in Germany the corresponding terms indicate only the order of succession. In making this statement he may find some justification in the writings of some of those who have previously discussed the point, but it may be well to recall the exact definition of "primary" given on English death certificates—"the disease which initiated the train of events leading to death, and not a mere secondary, contributory, or immediate cause, or a terminal condition or mode of death." We gather that Dr. Rosenfeld thinks that Virchow's pathological classification of diseases according to their localization, instead of according to their etiology, has prolonged certain errors in the records of causes of death. This does not prevent Dr. Rosenfeld from advocating a classification of tuberculous diseases according to their localization, though how he proposes to decide that tuberculosis of the lymphatic glands or of the genito-urinary system has not arisen from pulmonary tuberculosis, or vice versa, we have no means of deciding. Anyhow, though many of Dr. Rosenfeld's statements are interesting, we are by no means certain that they are of much practical value under the present chaotic system of death certification in the various countries he deals with. What we are certain about is this: that if the Health Organization of an important body like the League of Nations thinks a report worth translating into different languages, it should employ translators who can reproduce the ideas in the language appropriate to each country, and not incommode the reader by following too slavishly the phraseology of the author.

#### SILICOSIS IN POTTERS.

THE General Council of the Trades Union Congress asked the Secretary of State for Home Affairs in 1925 to take steps to schedule "potter's asthma," or silicosis, as an industrial disease under the Workmen's Compensation Act. The disease, however, could not be dealt with under this Act, but only by special powers obtained under the Workmen's Compensation (Silicosis) Acts of 1918 and 1924. Before deciding to apply these powers it was thought well to establish the facts as to the incidence of the disease; and an investigation has been carried out by Dr. E. L. Middleton, medical inspector of factories, with the help of Drs. C. L. Sutherland and S. Bryson, and of Dr. A. H. John of Stoke-on-Trent as radiologist. Their report<sup>1</sup> has now been published by the Home Office. For those who do not live in the Potteries the report seems in need of a glossary. Few people resident elsewhere will, we imagine, understand such terms as "slipmakers," "jiggerers," "jolliers," or "sagger makers." The observers are of opinion that silicosis exists in the workers in the pottery

industry to a very considerable degree, and they give a list of occupations practised in pottery work in which there is risk of the disease. We are left, however, to infer that the observers think a compensation scheme is desirable; we are only told that modellers, mouldmakers, and red marl workers, if subjected to special regulations, might be excluded from a scheme. Some interesting facts have been elicited by the investigation. Thus silicosis has been found, not only amongst those exposed to the inhalation of dry flint dust, but also in occupations such as the manufacture of earthenware, in which sand is used instead of flint; in flint-milling processes, in which the material is wet; and also in processes of manipulating the ware in the clay state before firing. Uncombined silica in the form of flint or quartz is the more important factor in causing serious respiratory disease in the industry. It appears that fibrosis of the lungs has been frequently diagnosed by medical examination earlier than silicosis has been found by radiological examination in the same occupational group. Apparently the great majority of cases were found to occur after twenty years' employment in the industry. In the report this assertion is followed by the statement: "It is significant that in the occupation where the incidence of silicosis is high it becomes evident at an early stage in the occupational history of the workers. This feature may be regarded as a true measure of the severity with which silicosis is likely to occur under given conditions." It is not clear whether this is meant to imply that silicosis in the Potteries is not a severe disease: the report gives no indication. Dr. Middleton writes that the report "should command the respect alike of those concerned with the conduct of the industry and of medical authorities who are interested in the health aspect of the subject"; nevertheless, we rise from its perusal without having acquired any precise idea of what it is thought ought to be done to remedy those disabilities to which it calls attention.

#### WEEK-END TUBERCULOSIS CONFERENCE.

A TUBERCULOSIS week-end has been arranged by the Tuberculosis Society and the Society of Superintendents of Tuberculosis Institutions from November 19th to the 22nd. Dr. Strandberg, of the Finsen Institute, Copenhagen, will read a paper on the first day, at 5 p.m., at the house of the Royal Society of Medicine, on treatment by heliotherapy and artificial light of tuberculosis, with special reference to laryngeal disease; the discussion will be opened by Sir StClair Thomson and by Mr. Somerville Hastings. This meeting will be followed by a dinner at 7 p.m., and in the evening a discussion will be held on Memorandum 37/T of the Ministry of Health. On November 20th excursions will be made to various sanatoriums and hospitals. A clinical demonstration will be given by Dr. L. S. Burrell on the morning of November 22nd at the Brompton Hospital, and this will be followed by lunch at the Welbeck Palace Hotel, where guests from foreign countries will be entertained. In the afternoon Dr. P. F. Armand-Delille of Paris will read a paper on the diagnosis of bronchiectasis and lung cavities by intratracheal injections of lipiodol. This paper will be illustrated by cinematograph films, and the discussion will be opened by Dr. F. G. Chandler. After tea Dr. George Schroder, medical director of the New Schönbürg Sanatorium, Würtemberg, will give an address with epidiascope illustrations on specific stimulant therapy and protective inoculation measures; the discussion will be opened by Dr. H. Hyslop Thomson, medical officer of health for Hertfordshire. Visitors interested in these discussions and excursions are cordially invited; further information may be obtained from Dr. J. R. Dingley, Darvell Hall Sanatorium, Robertsbridge, Sussex, or Dr. F. J. C. Blackmore, Tuberculosis Dispensary, Plumstead, S.E.18.

## Union of South Africa.

[FROM OUR CORRESPONDENT IN CAPE TOWN.]

MEDICAL ASSOCIATION OF SOUTH AFRICA (BRITISH MEDICAL ASSOCIATION), CAPE WESTERN BRANCH.

THE annual dinner of this Branch was held at Sea Point on September 29th. The occasion was noteworthy as being the first social function to be arranged by the Branch since assuming its new designation, and a company of close upon a hundred sat down. Dr. D. H. Wessels, president of the Branch, presided, and had on his right the mayor of Capetown, Mr. W. F. Fish, and on his left the chairman of the Cape Hospital Board, Mr. M. C. Vos, who is also mayor of the neighbouring township of Wynberg. Among other guests present were Mr. T. Lindsay Sandes, president of the Southern Peninsula Medical Society, and Mr. H. J. Barclay, president of the Dental Society of the Western Province, while not a few members entertained personal friends. After the customary loyal toasts had been proposed and duly honoured, Mr. M. C. Vos proposed the toast of the evening, "The Medical Association of South Africa (British Medical Association)." He heartily congratulated the medical profession on its newly obtained unity, and emphasized the point that from now onwards, on all matters pertaining to the public health and to its own interests as well, the profession could speak with one voice. The consummation of that very desirable ideal, the solidarity of the medical profession, was in large measure the direct result of the visit of Dr. Alfred Cox, Medical Secretary. In dealing with the Cape Hospital Board, a body which, rightly or wrongly, had fallen into disrepute both with the profession and the public, Mr. Vos foreshadowed that, with the reorganization about to be brought into effect, whereby the Board would be reduced in membership to exactly half of what hitherto had been its number, greater efficiency would be attained. In responding on behalf of the Medical Association of South Africa, Dr. Wessels thanked Mr. Vos for his good wishes, and called on Dr. C. L. Leipoldt, who, in a most admirable speech, drew attention to the fact that in the process of amalgamation both the British Medical Association and the South African Medical Association had made no little sacrifice. The toast of "The Medical School of Capetown" was given by Mr. H. A. Moffat, who pleaded for closer co-operation between the members of the university staff and the profession in general, and advocated the appointment of more of the younger men to subordinate posts on the teaching staff. Professor W. A. Jolly, dean of the Medical Faculty, replied in a speech brimful of dry humour, but dealt with Mr. Moffat's criticism in a serious vein, asking that more leniency be shown to a school of such recent birth. Dr. Royden Muir was allotted the privilege of proposing the health of the guests in a neat speech, to which Mr. Fish and Mr. Barclay responded. Thus ended a most successful function, which was thoroughly enjoyed by all present.

### PLAGUE MEASURES IN THE CAPE PROVINCE.

Reference has already on previous occasions been made here to the incidence of plague, more especially in the Transvaal and the Orange Free State, and to the investigation of the carrier problem, which is being carried out conjointly by the Department of Public Health and the South African Institute for Medical Research. In the Cape Province, plague infection in veld rodents is known to have existed in the Kenhardt district for some two years, and from time to time warnings have been issued that the disease in man might show itself south of the Orange River, the northern boundary of the north-western districts of the Province. Quite recently plague-infected rodents have been discovered in a more southerly direction—namely, the Williston and Calvinia districts, extending as far as a point some miles north of Nieuwoudtville. The first report of a suspected case in man in this area was made on June 11th last, and coincidentally suspected mortality among field rodents was recorded in the same tract of country. Since then further cases among human beings have occurred, and so menacing has the situation

become that a plague survey in the infested area has been instituted by the Department of Public Health. Dr. F. C. Willmot, assistant medical officer of health for the Union, has been actively engaged during the last few weeks in investigating what natural barriers exist to the southward, and how they may be utilized in any scheme directed to the prevention of the spread of infected rodents. There is a grave risk that enzootic infection in veld rodents may spread to the Van Rhynsdorp and Clanwilliam districts, and thence further south along the coastal belt through the areas of Piquetberg and Malmesbury to the Cape Peninsula. So far, however, no evidence of infection has been found in the Van Rhynsdorp and Clanwilliam districts. The north-western districts, to which reference has been made, are known to be heavily infested with the Namaqua gerbille and hares. In three of the recent cases in man the patients are said to have eaten or handled dead hares. The results of the plague survey to date show that useful natural barriers against spread by field rodents to the country south of the Olifants River exist in the Bokkerveld and Cedarberg Mountains and the Doorn and Olifants Rivers with their irrigation canals. The value of such natural barriers lies in the fact that veld rodents, with one or two exceptions, will not cross water, nor are they likely to resort to high-lying ground. The authorities intend to supplement these natural lines of defence by clearing field rodents along a wide belt of country north of the Olifants River.

### A MEDICAL MAYOR.

Very general satisfaction throughout the profession is felt at the election of Dr. P. A. Euvrard as mayor of Malmesbury, one of the most progressive of the country towns, situated in the heart of a fertile grain-growing district some thirty miles from Capetown. Dr. Euvrard, who had previously acted as deputy mayor, has been in general practice at Malmesbury since his return from Edinburgh, where he graduated M.B., Ch.B. in 1907. It is only fitting that his term of office should coincide with the inauguration of the new water supply system, recently officially opened by the Administrator of the Cape Province, a forward step which must prove a lasting benefit and exercise a marked influence for good on the health of the community.

### THE LATE DR. JASPER ANDERSON.

There was unveiled recently, at the City Hospital for Infectious Diseases, Capetown, a tablet to the memory of the late Dr. A. Jasper Anderson, first whole-time medical officer of health to the city of Capetown, who held office for a period of many years, and who, on his retirement owing to ill health in 1923, was succeeded by Dr. T. Shaddick Higgins. The tablet, which is of marble, with gilt lettering, is let into the front wall of the building on the left of the main entrance, and bears the following inscription: "1901-1923. In remembrance of A. Jasper Anderson, M.A., M.B.(Oxon.), D.P.H.(Cantab.), M.R.C.S., F.R.S.(S.A.), Medical Officer of Health of the City, who conducted this Hospital with marked ability and success." It is fitting, indeed, that the City Hospital should be chosen as the site of such a memorial, for it owes its establishment to Dr. Anderson's initiative, having been taken over by him from the military authorities on behalf of the city council, and having been his very special care for many years. Mrs. Councillor Walsh, chairman of the public health committee, in asking the mayor to unveil the tablet, said that it was to the memory of one of their most faithful and loyal servants, who had left behind him a record which was an example to all who were attempting to follow in his footsteps. The British Medical Association, Cape of Good Hope (Western) Branch, of which the late Dr. Jasper Anderson was a past president and one of its staunchest supporters, was represented at the ceremony by Mr. Cecil E. Jones-Phillipson, himself a past president and a member of council.

### NATIONAL AMBULANCE AND NURSING COMPETITION.

The annual competition in ambulance work and nursing organized by the South African Red Cross Society and the St. John Ambulance Brigade took place at Bloemfontein on October 1st and 2nd in the Rambler's Hall, where some hundred competitors paraded on the first day to take part

in the tests. The silver shield presented as a trophy by Earl Selborne in 1907 was won by the Pretoria Railway division, who scored 244½ marks out of a possible 310. The silver shield presented for competition to the nursing section by Dr. Bennie Hewat of Capetown was won by the Johannesburg Railway nursing division with a score of 251 out of 300. Thus both the honours of the first day went to the Transvaal. On the second day ten teams in the men's ambulance section competed for a trophy presented by the Central Mining and Investment Corporation, Ltd., being representative of the four provinces and Rhodesia. The test was to treat a man who had fallen from a balcony and had sustained a compound fracture of the left femur. The upper portion of the broken bone protruded from the flesh, and there was severe haemorrhage. In the nursing section the teams which competed for the Lady Hoy silver rose bowl were asked to treat a woman who, in an epileptic fit, had fallen on a stove, severely burning her face and sustaining a compound fracture of the left wrist.

At the annual meeting of the Central Council for South Africa of the Order of St. John of Jerusalem, presided over by Mr. Alpheus F. Williams of Kimberley, reference was made to the Salt River railway disaster, which occurred in June, 1926, at which most excellent work was performed by the railway members of the St. John Ambulance Brigade. A letter was read from a surgeon who was present at the accident, in which he remarked that he had never seen such efficient first-aid work; within forty minutes of the occurrence of the disaster all the injured, to the number of over fifty, had been treated and removed to hospital or their homes. In regard to development a number of new divisions of the St. John Ambulance Brigade have been formed, so that there are now seventy-two divisions and three sections of a division in the Union, and one division in Rhodesia. The translation of the St. John first-aid textbook into Afrikaans had been completed, and the first edition would soon be ready for issue.

#### UNIVERSITY OF CAPE TOWN: COMMEMORATION DAY.

The annual commemoration day of the University of Capetown took place on September 24th; it was celebrated by an at home given by Principal Sir Carruthers and Lady Beattie at the New University site, Groot Schuur. It was favoured by fine weather, and was attended by a large number of distinguished guests, who were received by the host and hostess on the lawn in front of the old summer house, where tea was served in the open to the accompaniment of music provided by the band of the Defence Force. The New University tennis courts, which number fifteen, were formally opened; they are built in terraces on the sloping ground, which rises gradually from the back of the principal's residence to the level of the university site proper, and should suffice for the requirements of tennis-loving students for many years to come. The opening ceremony was performed by Mr. Justice F. E. Watermeyer, a past student of the South African College, from which the university has developed. After the opening of the courts a match was played between teams representing the present students and the staff, together with past students; the result was a substantial victory for the older generation.

## England and Wales.

#### UNIVERSITY OF DURHAM COLLEGE OF MEDICINE, NEWCASTLE.

SIR THOMAS OLIVER, M.D., has been elected to succeed Sir David Drummond, M.D., as president of the University College of Medicine at Newcastle, and, as is customary, has been made also vice-chairman of the Court of Governors. Sir David Drummond has been a member of the council of the college for forty-seven years, and became president in 1918. His retirement from office is due to his home being now at a considerable distance from Newcastle. He will remain a member of the council. Members of the British Medical Association will recall that Sir David Drummond was President of the Association in 1921, at a time when his official duties included also the Vice-

Chancellorship of the University of Durham. A further change in the personnel of the college is taking place through the resignation of the honorary treasurer, Dr. Cecil Cochrane, after eighteen years' service. In that period the income of the college has increased from less than £10,000 to more than £30,000, while assets of £50,000 or £60,000 have grown to nearly £140,000. The year's deficiency of £487 has brought the total deficit in the working of the college to £2,111; but it is hoped that with improvement in industrial conditions the financial position will become better.

#### TUBERCULOSIS IN LANCASHIRE.

The economic and diagnostic value of the x-ray installations in each of the five tuberculosis dispensary areas of the administrative county of Lancashire is emphasized by the central tuberculosis officer (Dr. G. Lissant Cox) in his annual report for 1925. By frequent screen examinations and taking skiagrams during the course of the disease the tuberculosis officer becomes skilled in their interpretation, and early cases of infection are detected with greater facility and certainty. Help in determining the suitability of patients for institutional treatment is similarly available, and expense is thus reduced. An account of the radiological work during the year is contributed by Dr. J. Logan Steward, and, illustrated by radiograms, shows how effective this method of diagnosis has proved to be in the examination of contacts and in estimating the extent and nature of the disease. One interesting fact revealed by this routine radiological examination is that acute spontaneous pneumothorax, with partial collapse of the lung, is not uncommon in cases with pleurisy, the condition persisting only for a short time and expansion of the lung being completely restored. Research work has also proceeded with reference to the fate of young children of tuberculous households, comparison of home and sanatorium treatment, the circumstances attending the failure and lateness in notifying cases of tuberculosis, the proportion of cases diagnosed primarily by x-ray examinations and subsequently confirmed clinically, and the types of lamps and carbons most suitable for treatment by artificial light in dispensaries. In the last particular the long-flame carbon arc has so far been found to be the most effective, with the addition of a mercury vapour lamp for local treatment. During 1925 experimental artificial light centres were established at two dispensaries, and early in 1926 mercury vapour lamps were installed in Elswick Sanatorium and the Rufford Pulmonary Hospital. Dr. Lissant Cox gives reasons for disagreeing with the present tendency to reduce the size of the administrative areas in England and Scotland; he maintains that large units are necessary if provision is to be made for the adequate hospital, laboratory, and radiological accommodation, which, with well staffed dispensaries, should be co-ordinated in a really effective scheme for preventing as well as treating tuberculosis. To this may be added the important point that in larger areas the trial of new remedies can be made on a sufficiently large scale to be valuable, and overlapping of different authorities is avoided, while the proportion of cases notified is increased. Dr. Lissant Cox believes that it is impossible for a tuberculosis officer to become a real clinical expert if he is to deal with a population of under 150,000, taking on other kinds of work in addition. The average population of each of the five large dispensary areas in Lancashire is nearly 350,000. Another indication of the value of such concerted work on a large scale is afforded by the fact that the death rate for pulmonary tuberculosis per 100,000 of the population, which was 107 in 1918, has fallen almost steadily since then, and in the year under review reached the record low figure of 67. There are now eighteen voluntary care committees at work in the county covering a population of nearly 1,800,000. Co-operation with sanitary authorities and medical practitioners is very close, and the latter continue to send more than three-quarters of their patients to dispensaries for examination prior to notification. Dr. Lissant Cox mentions the need for better education of the public with regard to the symptoms and dangers of tuberculosis, and advocates instruction of the older school children in elementary hygiene and the laws of health.

## CENTRAL MIDWIVES BOARD.

The Central Midwives Board for England and Wales held a penal session on November 4th. Sir Francis Champneys, Bt., presided. In reply to a request for advice from the Joint Nursing and Midwives Council for Northern Ireland, the Board expressed the opinion that the fact that medical help became necessary to apply forceps did not prevent a case being counted to a pupil, provided that the pupil had made abdominal and vaginal examinations. The Board considered, however, that cases of Caesarean section should not count to a pupil. Dr. Harrison, resident medical officer, was approved as a lecturer to pupil midwives at Bagthorpe Infirmary, Nottingham, for six months pending the arrangement of a scheme with the authorities of the Collin's Trust Maternity Home, for the delivery of a single course of lectures in Nottingham. The report on the work of the Board for the year ending March 31st, 1926, was amended and approved, and signed by the chairman and secretary for transmission to the Ministry of Health.

## THE MEDICAL MAYOR OF EXETER.

The new Mayor of Exeter, Mr. Ransom Pickard, is a distinguished member of the medical profession. After studying at St. Bartholomew's Hospital he graduated M.S.Lond. in 1892, and M.D. in 1893, having obtained the diploma F.R.C.S. in the previous year. He commanded the 1st Wessex Field Ambulance from its formation until July, 1917, when he became A.D.M.S. of the 48th South Midland Division, holding this post until demobilization in April, 1919. He landed in France with the 8th Division in November, 1914, and left France for Italy with the 48th Division in November, 1917. He was engaged in repatriating prisoners of war from Bavaria and the Tyrol during the winter of 1918-19. He was mentioned in dispatches five times, and obtained the Mons star and the Italian Croce di Guerra. For his distinguished services he was awarded the C.B. and the C.M.G. For several years Mr. Ransom Pickard has been a member of the South-Western Branch Council of the British Medical Association; he was vice-president of the Section of Ophthalmology at the Annual Meeting in 1923, and he is a member of the central Ophthalmic Committee.

## Scotland.

## INFLUENCE OF FOOD ON HEALTH.

THE sixth annual conference of the Scottish Council of Women Citizens' Associations was held at Dumfries on October 30th. Lady Leslie Mackenzie, chairman of the council, presided, and Dr. Chalmers Watson (Edinburgh) gave an address on "Diet and sunshine," in which he said that the best results in regard to prevention of disease could only be obtained by intelligent co-operation between the educated public and the medical profession. He referred to the remarkable evolution in recognition of disease conditions which had taken place in the last twenty or thirty years, and expressed the belief that many diseases now commonly recognized as adenoids, appendicitis, pyorrhoea, and neurasthenia were largely dependent on changes that had taken place in diet. There had been a gradual diminution in the consumption of natural foods, which had been replaced by foods prepared or preserved by methods which interfered with their nutritive value. He believed that medical treatment required by children of middle-class families, which commonly involved operations for removal of adenoids, later for appendicitis, and later still regular dental attention for the development of trouble in the teeth, was directly due to the parents' ignorance of the fundamental laws of sound nutrition. The nation, he believed, had departed a long way from the system of nutrition which had reared in the past a race that was physically and mentally virile. In the past twenty years the nutritive value of bread had been enormously impaired by artificial methods of treatment in response to the public demand for a white bread. The consumption of oatmeal, which formerly entered largely into the national dietary in Scotland, had fallen. The amount of milk consumed

per head was very far behind the figure in America and Denmark. He believed that for the early periods of growth pure milk supplied from tuberculin-tested cows was the most valuable foodstuff available, and that its greater use could be advantageously extended to the young adult. At the present day large sums of money were annually spent in the purchase of proprietary milk foods, which were both more expensive and less valuable than the natural product. Most of the diseases of old age, also, he held to be preventable. At a later stage of life neurasthenia, rheumatism, high blood pressure, and kidney or heart disorders, and later still premature old age, were largely due to a defective system of feeding and drinking. It was important, too, to remember that sunshine entered largely into the formation of good milk as well as into the composition of vegetables and fruits, which could advantageously be eaten raw. Dr. Livingston, Convener of the Public Health Committee of Dumfries Town Council, emphasized the point with regard to the necessity for proper care of the teeth in the prevention of disease. He believed that if Robert Burns were alive to-day he might have modified his grace before meat to read:

"Some ha'e meat an' canna eat,  
An' some would eat that want it,  
But we ha'e meat and we can eat,  
God gi'e us teeth to munch it."

Dr. Joseph Hunter, M.O.H. for Dumfries, said that dietetic reforms had made less impression on the general public than was desirable, largely because there were so many faddists and cranks in regard to what ought and ought not to be eaten. Common sense should be applied to this matter, and articles of diet found unsuitable for individuals should be withdrawn from the daily diet. Mr. Allan W. Ritchie, chief sanitary inspector, Edinburgh, in a paper on food handling, urged that cleanly practices were necessary in every aspect of food supply, from the place of production to the home of the consumer. Progress had been made in regard to bread by the provision of many hygienic bakeries, but in the generality of bakehouses there was still need for a higher standard. A system of medical examination of persons employed in certain sections of the food industry was urgently required. The exposure of food in shop windows and on counters and shelves, although intended to attract customers, should arouse repulsion, owing to the possibility of contamination by dust and flies, and shops connected directly with dwelling-houses were unsuitable. He thought that improvement could be achieved both by education and by legislation. The conference passed a resolution urging upon the Scottish Board of Health that local authorities should be provided with further powers to control by registration, regulations, or inspection all places where food is produced, sold, stored, and distributed.

## DAIRY RESEARCH.

At a special meeting of the governors of the West of Scotland Agricultural College, held in Glasgow on November 1st, the proposal of the Secretary of State for Scotland for the establishment of a dairy research institute for Scotland was considered. An offer was made about a year ago by Mr. John M. Hannah of Girvan to give a portion of the estate of Auchincruive, Ayr, including a mansion house, to the governors of the college, for the purpose of an agricultural college and dairy school. The offer, however, involved the transfer of the college in Glasgow to Auchincruive, and the governors, therefore, had rejected it. In the interval the offer had again been made to the Secretary of State for Scotland for the purpose of furthering agricultural education and research in the south-west of Scotland, with the special view of affording courses in agriculture and dairy research. At a meeting of representatives of the University of Glasgow and the Agricultural College on October 13th the Secretary of State had expressed the view that a dairy research institute should be promoted in the West of Scotland, that it should be in close relation to the Agricultural College, although under its own governing body, and that the estate of Auchincruive was suitable for such a research institute, where courses on dairy management might be given. A committee of the college had pointed out that Kilmarnock

was the recognized dairy research centre in Scotland, just as Reading was in England, and appeared to deprecate the formation of another dairy research institute largely independent of the College of Agriculture. It proposed the setting up of a joint university and college committee to carry out the work, but suggested that, subject to suitable arrangements being made, the college department now located at Kilmarnock might be transferred to Auchincruive. It was decided to defer consideration of the question.

#### DUNDEE EYE INSTITUTION.

The report presented to the annual meeting of the Dundee Eye Institution showed that 3,730 patients had been treated during the year—2,929 from Dundee and the remainder from a wide district in the surrounding country. During the ninety years of the institution's existence over 139,000 cases in all have been treated. Each patient made on the average about five visits to the institution during the course of the year. Greater financial assistance from country districts was needed; one district which had sent about seventy cases to the institution had contributed only 7s. 6d. There was a credit balance at the end of the year of £69.

#### GIFTS TO GLASGOW ROYAL INFIRMARY.

The gift of an area of land to the Glasgow Royal Infirmary by Mr. James Macfarlane, LL.D., one of the directors, and his brother, Mr. George W. Macfarlane, on which an auxiliary convalescent hospital is to be erected at Canniesburn, was announced some time ago. The donors have now arranged to present a still more extensive area, in the belief that future developments might make a larger site desirable. To the twenty-two acres previously given, nine and a half acres have been added, and the whole of the feu duty and other annual payments is to be redeemed by the donors. Towards the cost of building the auxiliary hospital, Miss Clark, a Glasgow lady, has given £10,000 in memory of her father, Dr. Samuel Clark. The building fund now amounts to £23,500.

## Ireland.

#### CRIPPLED CHILDREN.

DURING a recent visit to Dublin Sir Robert Jones addressed several meetings in connexion with the problem of the crippled child. He expressed his approval of the proposal to co-ordinate the various cripple institutions in the country, and said that the first thing to do was to ascertain the number of patients that would have to be dealt with. Where a census of cripples had been taken, as in America and some other countries, it had been found that there were five cripples to every thousand persons. If that ratio held in the Irish Free State it must contain 12,000 or 14,000 cripples. The chief diseases that caused crippling were tuberculosis and rickets. In addition there were the cases of congenital deformity and deformity produced by injury. In England at the present time cases of infantile paralysis were occurring in fairly large numbers, but there had been a serious epidemic in America which had produced 13,000 deaths; 25 per cent. of cases of deformity were due to rickets, and about 50 per cent. to tuberculous disease. About 50 per cent. of the cases of tuberculosis of the bones and joints were to be traced to milk, and about 30 per cent. to direct contact with the human consumptive. In England it had been found that one out of ten specimens of milk examined contained living tubercle bacilli. It was absolutely essential that there should be some real strict supervision, municipal or other, of the milk that was brought into every city. That supervision should be so effectual that it would be impossible for a dirty dairyman or a dirty cow to infect the children. It should be possible to prevent the conveyance of infection from a consumptive to his child or relatives. Sir Robert Jones went on to say that he had visited the Dublin hospitals and thought the work done there was absolutely splendid, but the conditions under which the surgeons in
